The path chosen by a galvanic current is no secure indication of the course which will be taken by a lightning flash. The course of a trickle down a hill side does not determine the path of an avalanche. Lightning will not select the easiest path alone; it can distribute itself among any number of possible paths, and can make paths for itself. Ordinary testing of conductors is therefore no guarantee of safety, and may be misleading. At the same time it is quite right to have some system of testing and of inspection, else rust and building alterations may render any protector useless.

There is no space near a rod which can be definitely styled an area of protection, for it is possible to receive violent sparks or shocks from the conductor itself. Not to speak of the innumerable secondary discharges which, by reason of electro-kinetic momentum and of induction and of the curious recently discovered effect of the ultra violet light of a spark, are liable to occur as secondary effects in the wake of the main flash.

Just one word on the subject of iron *versus* copper. The writer last year thought and stated that, in so far as the substance of the conductor was magnetised by a discharge, iron would obstruct a lightning flash or any other rapidly varying current enormously more than copper does. But the fact is, that the substance of a conductor is, by sufficiently rapidly alternating currents, not magnetised at all. The current is tubular, keeps wholly to the outer surface, and magnetises nothing inside. Hence the magnetisability of the substance of the conductor is of no moment at all, and iron, therefore, will do every bit as well as copper. Mr. Preece's experience with half a mile of iron wire telegraph post protectors leads him to uphold iron as entirely satisfactory. So on the one point, as well as on the necessity existing for a good earth, a portion of the practical and of the theoretical camp have been able to agree.

Immediately after the discussion Dr. Lodge exhibited some preliminary attempts at photographing lightning taken with a double-necked camera, having two sensitive plates, one fixed, the other revolving 30 times a second.* The same flash was depicted on both plates, but on the moving plate it was separated into two or three distinct streaks, showing its multiple character. Each constituent, however, was as clear and distinct on the rotating as on the fixed plate, and had in fact exactly the same shape and appearance, so that one could be superposed on the other exactly; thus proving its instantaneous character. The rate of spin was naturally nothing like sufficient to exhibit the alternating character of each constituent.

It is to be hoped that many more photographs of flashes will be taken on this plan, because they are evidently in many kinds of composite flashes, and it is an excellent way of analysing them and correcting the impressions, often erroneous, formed by the eye.

On the whole, the Bath meeting, though not largely attended by the temporary class of members and associates, may be considered, so far as Section A is concerned, as one of the most interesting and important that have ever been held; thanks largely to the excellent arrangements made by the Secretaries, and the discussions of Hertz's researches by the President in his address, mark a distinct epoch in our acquaintance with electromagnetic phenomena.

HERTZ'S RESEARCHES ON ELECTRICAL OSCILLATIONS.

BY C. W. DE TUNZELMANN.

(Continued from page 636.)

Node.—The vibrations in the micrometer circuit which have been considered are the simplest ones possible, but not the only ones. While the potential at the ends alternates between two fixed limits, that at the central portion of the circuit retains a constant mean value. The electrical vibration, therefore, has a node at the centre, and this will be the only nodal point. Its existence may be proved by placing a small insulated sphere close to various portions of the micrometer circuit while sparks are passing at the discharger of the coil, when it will be found that if the sphere is placed close to the centre of the circuit the sparking will be very slight, increasing as the sphere is moved further away. The sparking cannot, however, be entirely got rid of, and there is a better way of determining the existence and position of the node. After adjusting the two circuits to unison, and drawing the micrometer terminals so far apart that sparks can only be made to pass by means of resonant action, let different parts of the circuit be touched by a conductor of some capacity, when it will be found that the sparks disappear, owing to interference with the resonant action, except when the point of contact is at the centre of the circuit. He then endeavoured to produce a vibration with two nodes, and for this purpose he modified the apparatus previously used by adding to the micrometer circuit a second resonator, E F, exactly similar to the first (as shown in Fig. 7), and joining the points of the circuit near the terminals by wires L and L, as shown in the diagram.

The whole system then formed a closed metallic circuit, the fundamental vibration of which would have two nodes. Since the period of this vibration would necessarily agree closely with that of each half of the circuit, and, therefore, with that of the circuit C C, it was to be expected that the vibration would have a pair of loops at the junctions L1 and 21,

* The Eruption of Krakatoa, a pamphlet by E. Douglas Archibald, Tunbridge Wells; or the Report of the Krakatoa Committee.

* See a letter in *Nature*, July 12, 1888.

35582

and a pair of nodes at the middle points of *cd* and *gh*. The vibrations were determined by measuring the sparking distance between the micrometer terminals 1 and 2. It was found that, contrary to what was expected, the addition of the second reet[illegible] diminished this sparking distance from about 5 millimetres to about 1 millimetre. The existence of resonant action between the circuit C C and the micrometer circuit was, however, fully demonstrated for any alteration in the circuit *e f g h*, whether it consisted in motion of a slider decreasing its length, diminished the sparking distance. It was also found that much weaker sparks took place between *e f g h* and an insulated sphere, than between it and the same sphere, showing that the nodes were in *f* and *g*, as expected. Further, when the sphere was made to touch *ef* or *gh* it had no effect on the sparking distance of 1 and 2; but when the point of contact was at any other portion of the circuit the sparking distance was diminished, showing that these nodes really belong to the circuit to the resonant action of which increased this spark distance.

The wire joining the points 1 and 1 was then removed. As the strength of the induced oscillatory current should be zero at these points the removal ought not to disturb the vibrations, and this was shown experimentally to be the case, the resonant effect and the position of the nodes remaining unchanged. The vibration with two nodal points was, of course, not the fundamental vibration of the circuit, which consisted of a vibration with a node between *e* and *c*, and for which the highest value of the potential were at the points 1 and 1.

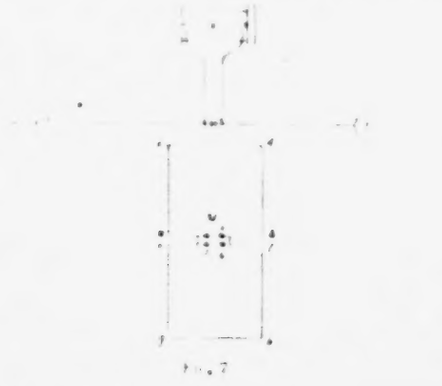

Fig. 7.

When the spheres forming the terminals at these points were brought close together slight sparking was found to take place between them, which was attributed to the excitation, though only to a small extent, of the fundamental vibration. This explanation was confirmed in the following manner. The sparks between 1 and 1 were broken off, leaving only the sparks between 2 and 4, which measured the intensity of the fundamental vibration. The period of vibration of the circuit C C was then increased by drawing it out to its full length, and thereby increasing its capacity, when it was observed that the sparking gradually increased to a maximum, and then began to diminish again. The maximum value must evidently occur when the period of vibration of the circuit C C is the same as that of the fundamental vibration of the micrometer circuit, and it was shown that when the sparking distance between 2 and 4 had its maximum value, the sparks corresponded to a vibration with only one nodal point, for the sparks ceased when the previously existing nodes were touched by a conductor, and the only point where contact could take place without effect on the sparking was between *e* and *g*. These results show that it is possible to excite at will in the same conductor, either the fundamental vibration or its first overtone, to use the language of acoustics.

Hertz appears to consider it very doubtful whether it will be possible to get higher overtones of electrical vibration, the difficulty of obtaining such lying not only in the method of observation, but also in the nature of the oscillations themselves. The intensity of these is found to vary considerably during a series of discharges from the coil even when all circumstances are maintained as constant as possible, and the comparative feebleness of the resonant effects shows that there must be a considerable amount of damping. There are, however, many secondary phenomena which seem to indicate that irregular vibrations are superposed upon the regular ones, as would be expected in complex systems of conductors. If, therefore, we wish to compare electrical oscillations from a mathematical point of view, with those of acoustics, we must seek our analogy in the high notes intermixed with irregular vibrations, obtained say, by striking a wooden bar with a hammer rather than in the comparatively simple harmonic vibration of tuning forks, or strings; and in the complex vibrations of the former class we have to be contented to rest in the study of acoustics, with little more than indications of such phenomena as resonance and nodal points.

Referring to the conditions to be fulfilled in order to obtain the best results, should other physicists desire to repeat the experiments Dr. Hertz notes a fact of very considerable interest and novelty, namely, that the spark from the discharger should always be visible from the micrometer, as when this was not the case, though the phenomena observed were of the same character, the sparking distance was invariably diminished. This effect of the light from the spark of an induction coil in increasing the sparking distance in the secondary circuit of another coil excited great interest when referred to by Dr. Lodge in the course of the recent discussion on lightning conductors at the British Association, and he pointed out that the same effect was produced by light from burning magnesium wire, or other sources rich in the ultra violet rays.

Theory of the Experiments.—The theories of electrical oscillations which have been developed by Sir William Thomson, Helmholtz and Kirchhoff have been shown* to hold good for the open circuit oscillations of induction apparatus, such as for the oscillation Leyden jar discharge, and, although Dr. Hertz has not succeeded in obtaining definite quantitative results to compare with theory, it is of interest to inquire whether the observed results are of the same order as those indicated by theory.

Hertz considers, in the first place, the vibration period. Let T be the period of a single or half vibration proper to the conductor existing the micrometer circuit. If its coefficient of self induction in absolute electromagnetic measure, expressed therefore, in centimetres, C the capacity of one of the terminals in electrostatic measure, and, therefore, also expressed in centimetres, and v the velocity of light in centimetres per second.

Then if the resistance of the conductor is small,

$$T = \pi \sqrt{LC}$$

In the case of the resonance experiments the capacity C was approximately the radius of the sphere forming the terminal, so that C = 1·5 centimetre. The coefficient of self induction was that of a wire of length 1·5 centimetre and diameter 0·2 centimetre.

According to Neumann's formula

$$L = 4\left(\log\frac{4l}{d} - 0{\cdot}75\right)$$

which gives in the case considered

$$L = 22\left(\log\frac{1}{d} - 0{\cdot}75\right) = 19{\cdot}62\text{cm}$$

As, however, it is not quite certain that Neumann's formula is applicable to an open circuit, it is better to use von Helmholtz's more general formula, containing an undetermined constant *k*, according to which

$$L = 2\left(\log\frac{4l}{d} - 0{\cdot}75 + \frac{k}{2}\right)$$

Putting *k* = 1 this reduces to Neumann's formula, for which it reduces to that of Maxwell, and for *k* = 0 to Weber's. The greatest difference in the values of L obtained by giving these different values to *k* would not exceed a sixth of its mean value, and, therefore, for the purposes of the present approx-

* Lorentz, Wied. Ann. d. Phys. Vol. VII. p. 161. 1879.

3139

[illegible] it is enough to assume that l is not a large positive or negative number, for if the number 1·07 does not give [illegible] value of the coefficient for the wire [illegible] in length, [illegible] give the value corresponding to a coefficient not differ[illegible] from it in length.

[illegible] we have $= \frac{1}{2}CP$ [illegible] which gives the distance travelled by light during the oscillation according to Maxwell's theory, the length of an electromagnetic wave. The value of P is then found to be [illegible] millionths of a second, which is of the same order as [illegible] results.

The ratio of damping is then considered. In order that [illegible] may be possible the resistance of the open circuit [illegible] less than $2\sqrt{LC}$. For the existing circuit [illegible] ohms as the upper limit of resistance. If the actual [illegible] is sensibly below this limit, the ratio of [illegible]

[illegible] The amplitude will therefore be reduced in [illegible] in

$$2P \quad \text{[illegible]}$$

$$e^{\frac{P}{T}} = N \quad \text{[illegible]}$$

[illegible] We have unfortunately no means of determining [illegible] of the air space traversed by the spark, but as [illegible] of a strong electric arc is never less than a few [illegible] he justified in assuming this as the minimum. [illegible] from this it would follow that the number of oscillations [illegible] to a single impulse must be reckoned in tens and [illegible] hundreds of thousands which is in accordance with the [illegible] of the experimental results and agrees with the [illegible] discussed in the case of the oscillatory [illegible] jar.

In the case of closed metallic circuits on the other [illegible] theory indicates that the number of oscillations before [illegible] is attained must be reckoned by millions and [illegible]

[illegible] Congress lastly, the order of the [illegible] of [illegible] according to theory and [illegible] observed. Besides this it must be noted that the maximum [illegible] induced by the oscillation in its own circuit is approximately [illegible] to the maximum potential difference [illegible] that there were no damping these quantities would be [illegible] since at a moment the potential difference at the extremities and the E.M.F. of induction would be a counterbalance. In the experiments under consideration the potential difference at the extremities was such as to give a spark 7 to 8 mm. in length, which must therefore represent the maximum induction exerted in its own circuit by the oscillation. Now at any instant the induced E.M.F. in the micrometer [illegible] must be to that in the exciting conductor in the same ratio as that of the coefficient of mutual induction M of the two circuits to the coefficient of self-induction P of the exciting circuit. The value of M for the case considered is easily calculated from the ordinary formulæ, and it is found to be between one-tenth and one-twelfth of P. This would only give a spark of from 7/10 to 8/12 mm. in length, so that according to theory visible sparks ought in any case to be obtained; but, on the other hand, sparks several millimetres in length, as obtained in the experiments previously described, can [illegible] explained on the assumption that the successive impulses produce an accumulative effect, so that theory indicates the necessity of the existence of the resonant effects [illegible] observed.

(To be continued.)

ON THE APPLICATION OF ELECTRICITY TO THE WORKING OF A 20 TON TRAVELLING CRANE.*

[illegible] ATKINSON, M. Inst. C.E.

[illegible] traveling cranes in the foundry of the Leith [illegible] are usually constructed to be worked by hand [illegible] but it had been much desired for the application of water [illegible] of the future time.

The crane is 70ft. span, and consists of a pair of wrought iron girders resting on end carriages, each running on two wheels on an elevated line of rails. The gearing for hoisting, for longitudinal and for cross traverse is secured on [illegible] the opposite ends of the crane-beam projection from the [illegible] which [illegible] the same time [illegible] a pulley [illegible] the chain [illegible] to pull on the cross traverse [illegible] which [illegible] to the main girders. By this arrangement the crane can [illegible] both and the hook can come within 4ft. of the wall.

The [illegible] and were attended [illegible] of [illegible] [illegible] a long main [illegible] and the cost and special attention required by a [illegible] induced the writer to try whether electricity might not be used with [illegible] Messrs. Lowell Parker, of Wolverhampton, were [illegible] and these gentlemen undertook to supply the dynamo and a motor suitable for the purpose, [illegible] a heavy crane.

The [illegible] which is considerably larger than is needed for the crane in question, is arranged to give [illegible] at 120 volts with 1,000 revolutions per minute. The armature of the cylinder type, but it [illegible] would [illegible] [illegible] of armature of 0·1 ohm and of the magnets 0·2 ohm. It is [illegible] to the main boiler house of the [illegible] and driven by a horizontal engine having a cylinder [illegible] stroke, running at 150 revolutions with [illegible] to [illegible] of a link belt. The leads from the boiler to [illegible] the [illegible] on the foundry floor [illegible] and [illegible] 0·1 W.G. copper wire, which the conductor in the trolley is formed [illegible] [illegible] the whole [illegible] that the [illegible] is [illegible] ground, and protected [illegible] and [illegible] the main pillar supporting the [illegible] by wood blocks. The [illegible] [illegible] which the crane runs, the [illegible] especially by copper strips. The [illegible] Lowell Parker's latest type, which [illegible] [illegible] armature, without wood [illegible] [illegible] [illegible] [illegible] the armature [illegible] [illegible] the [illegible] [illegible] [illegible] the working gear [illegible] the crane beside [illegible] the main girder. It [illegible] [illegible] carries a steel pinion, which [illegible] [illegible] bevel [illegible] a shaft which [illegible] [illegible] the top of the girder, and is connected [illegible] [illegible] with friction clutch connection to the [illegible] shaft which [illegible] mand the several movements of the crane, the means of using the hand power being still retained. Two sets of speed are arranged for each of the movements, namely:

	Slow speed	Fast speed
Hoisting	[illegible] ft.	10ft.
Cross traverse	25 ,,	100 ,,
Longitudinal traverse	75 ,,	213 ,,

To provide against [illegible] current passing through the motor an automatic magnetic cut-out is fixed on the crane, and as an additional security a fusible wire is placed close to the dynamo to provide for the contingency of a short circuit. For the purpose of varying the power and speed to meet the requirements of the foundry a set of resistance coils is provided, governed by a special switch by means of which different resistances can be introduced into the armature circuit of the motor, and the current can be cut off altogether, but so that it must be done by steps and not suddenly. In starting the motor the reverse action takes place. The shunt coils of the magnets are connected to the two collectors so that the fields are always excited when the dynamo is running, whether the motor is working or not, the switch controlling only the armature circuit. The collector for the angle-iron conductor consists of a pair of insulated brass blocks pressed against it by means of a flat spring having a considerable range. An ordinary wire brush serves to collect the current from the rail, but the axle of one of the wheels is [illegible] to this brush to provide for the contact being in any way interrupted.

The handles for operating the several movements, the brake lever, the switch, and the automatic cut-out are all collected

of some electricity, either with or through a conductor. Now, whenever electricity moves, it at once has magnetic properties, its motion generates a magnetic field. When the motion ceases the field at once subsides, and in subsiding it may produce a succession of diffusing and dying away induction currents in neighbouring conductors, or it may, if the circuit be an incomplete one, leave a permanent vestige of itself in the dielectric as a field of strained ether this state of strain being what we call electrostatic potential, and the field being familiar to us as an electrostatic field.

Generating it in this way, all distinction between rate of propagation of electrostatic and electromagnetic potential vanishes, they both travel together with the velocity of light, or rather, the thing which travels is the magnetic potential, and its permanent effect is *sita* is the electrostatic potential.

Thus, once more, the difficulty of a longitudinal or pressural wave disappears from the electrical theory of light, into which it had seemed to intrude itself, and Ψ is left to enjoy "a long and useful career," though it is not permitted an infinite or any other rate of propagation in its own proper nature. The question of the incompressibility or compressibility of the ether thus remains unanswered, and, as it would seem, unanswerable, by any such experiments as those of Hertz, or by any experiments on the rate of transmission of electrostatic potential. If any one asks how soon will the pull of a suddenly electrified body be felt at a distance? one may answer, "As soon as the charging spark is seen." But if it be asked at what rate electrostatic potential travels, the answer is that it does not travel, but is generated in *situ* by the subsidence of a magnetic potential which travels with the velocity of light.

It must be understood that the last word has by no means been said on these great problems, and that what I have here written must be digested with salt. It is proper also to record the conviction expressed by the President that most of these refined points would probably be found mathematically treated somewhere in the writings of Mr. Heaviside.

(To be continued.)

HERTZ'S RESEARCHES ON ELECTRICAL OSCILLATIONS.

BY G. W. DE TUNZELMANN, B.SC.

(Continued from page 589.)

In a note in Wiedemann's *Annalen*, Vol. XXXI., page 545, Dr. Hertz states that since the publication of his Paper in the same volume, he had found that von Bezold had published a Paper in 1870 (Poggendorff's *Annalen*, Vol. CXL., page 541), in which he had arrived by a different method of experimenting at similar results and conclusions as those given by him under the head of Preliminary Experiments.

Induction Phenomena in Open Circuits.—In order to test more fully his conclusion that the sparks obtained in the experiments described in my last Paper were due to self-induction, Dr. Hertz placed a rectangle of copper wire with sides 10 and 20 centimetres in length respectively, broken by a short air space, with one of its sides parallel and close to various portions of the secondary circuit of the coil, and of the micrometer circuit, with solid dielectrics interposed, to obviate the possibility of sparking across, and he found that sparking in this rectangle invariably accompanied the discharges of the induction coil, the longest sparks being obtained when a side of the rectangle was close to the discharger.

A copper wire, *i g k* (Fig. 3), was next attached to the discharger, and a side of the micrometer circuit, which was supported on an insulating stand, was placed parallel to a portion of this wire, as shown in the diagram. The sparks at M were then found to be extremely feeble until a conductor, C, was attached to the free end, *k*, of the copper wire, when they increased to one or two millimetres in length. That the action of C was not an electrostatic one was shown by its producing no effect when attached at *g* instead of at *k*. When the knobs of the discharger B were so far separated that no sparking took place there, the sparks at M were also found to disappear, showing that these were due to the sudden discharges and not to the charging current. The sparks at the discharger which produced the most effect at the micrometer were of the same character as those described in my last Paper. Sparks were also found to occur between the micrometer circuit and insulated conductors in its vicinity. The sparks became much shorter when conductors of larger capacity were attached to the micrometer knobs, or when these were touched by the hand, showing that the quantity of electricity in motion was too small to charge these conductors to a similarly high potential. Joining the micrometer knobs by a wet thread did not perceptibly diminish the strength of the sparks. The effects in the micrometer circuit were not of sufficient strength to produce any sensation when it was touched or the circuit completed through the body.

In order to obtain further confirmation of the oscillatory nature of the current in the circuit *k i h g* (Fig. 3), the conductor C was again attached to *k*, and the micrometer knobs drawn apart until sparks only passed singly. A second conductor, C', as nearly as possible similar to C, was then attached to *k*, when a stream of sparks was immediately observed, and it

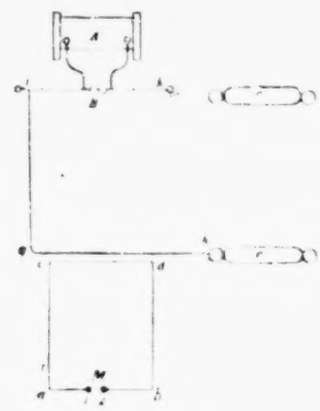

Fig. 3.

continued when the knobs were drawn still further apart. This effect could not be ascribed to a direct action of the portion of circuit *i k*, for in this case the action of the portion of circuit *g h* would be weakened, and it must therefore have consisted in C acting on the discharging current of C', a result which would be quite incomprehensible unless the current in *g h* were of an oscillatory character.

Since an oscillatory motion between C and C' is essential for the production of powerful inductive effects, it will not be sufficient for the spark to occur in an excessively short time, but the resistance must at the same time not exceed certain limits. The inductive effects will therefore be excessively small if the induction coil included in the circuit C C' is replaced by an electrical machine charging and discharging itself, or if too small an induction coil is used; or, again, if the air space between the discharger knobs is too great, as in all these cases the motion ceases to be oscillatory.

The reason that the discharges of a powerful induction coil gives rise to oscillatory motion is that, firstly, it charges the terminals C and C' to a high potential; secondly, it produces a sudden spark in the intervening circuit; and, thirdly, as soon as the discharge begins the resistance of the air space is so much reduced as to allow of oscillatory motion being set up. If the terminal conductors are of very large capacity, for example, if the terminals are in connection with a battery, the current of discharge may indefinitely reduce the resistance of the air space, but when the terminal conductors are of small capacity this must be done by a separate discharge, and there-

25385

fore, under the conditions of the author's experiments, an induction coil was absolutely essential for the production of the oscillations.

As the induced sparks in the experiment last described were several millimetres in length, the author modified it by using the arrangement shown in Fig. 4, and greatly increasing the distance between the micrometer circuit and the secondary circuit of the induction coil. The terminal conductors C and C' were three metres apart, and the wire between them was of copper, 2 millimetres in diameter, with the discharger B at its centre.

The micrometer circuit consisted, as in the preceding experiments, of a rectangle 80 centimetres broad by 120 centimetres long. With the nearest side of the micrometer circuit at a distance of half a millimetre from C B C sparks two millimetres in length were obtained at M, and though the length of the sparks decreased rapidly as the distance of the micrometer circuit was increased, a continuous stream of sparks was still obtained at a distance of one and a half metres. The intervention of the observer's body between the micrometer circuit and the wire C B C produced no visible effect on the stream of sparks at M. That the effect was really due to the rectilinear conductor C B C was proved by the fact that when one or other, or both halves of this conductor were removed, the sparks at M ceased. The same effect was produced by drawing the knobs of the discharger B apart until sparks ceased to pass, showing that the effect was not due to the electrostatic potential difference of C and C', as this would be increased by separating the discharger knobs beyond sparking distance.

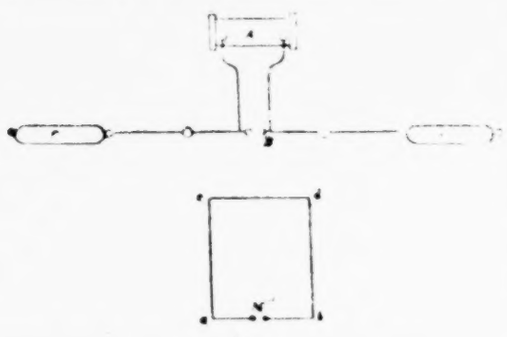

FIG. 4.

The closed micrometer circuit was then replaced by a straight copper wire, slightly shorter than the distance C C', placed parallel to C B C', and at a distance of 60 centimetres from it. This wire terminated in knobs, 10 centimetres in diameter, attached to insulating supports, and the spark micrometer divided it into two equal parts. Under these circumstances, sparks were obtained at the micrometer, as before.

With the rectilinear open micrometer circuit sparks were still observed at the micrometer when the discharger knobs of the secondary coil circuit were separated beyond sparking distance. This was, of course, due simply to electrostatic induction, and shows that the oscillatory current in C C' was superposed upon the ordinary discharges. The electrostatic action could be got rid of by joining the micrometer knobs by means of a damp thread. The conductivity of this thread was therefore sufficient to afford a passage to the comparatively slow alternations of the coil discharge, but was not sufficient to provide a passage for the immeasureably more rapid alternations of the oscillatory current. Considerable sparking took place at the micrometer when its distance from C B C was 1·2 metres, and faint sparks were distinguishable up to 3 metres. At these distances it was not necessary to use the damp thread to get rid of the electrostatic action, as, owing to its diminishing more rapidly with increase of distance than the effect of the current induction, it was no longer able to produce sparks in the micrometer, as was proved by separating the discharger knobs beyond sparking distance, when sparks could no longer be perceived at the micrometer.

Resonance Phenomena.—In order to determine whether, as some minor phenomena had led the author to suppose, the oscillations were of the nature of a regular vibration, he availed himself of the principle of resonance. According to this principle, an oscillatory current of definite period would, other conditions being the same, exert a much greater inductive effect upon one of equal period than upon one differing even slightly from it.*

If, then, two circuits are taken having as nearly as possible equal vibration periods, the effect of one upon the other will be diminished by altering either the capacity or the coefficient of self induction of one of them, as a change in either of them would alter the period of vibration of the circuit.

This was carried out by means of an arrangement very similar to that of Fig. 4. The conductor C C' was replaced by a straight copper wire 2·6 metres in length and 5 millimetres in diameter, divided into two equal parts as before by a discharger. The discharger knobs were attached directly to the secondary terminals of the induction coil. Two hollow zinc spheres, 30 centimetres in diameter, were made to slide on the wire, one on each side of the discharger, and since, electrically speaking, these formed the terminals of the conductor, its length could be varied by altering their position. The micrometer circuit was chosen of such dimensions as to have, if the author's hypothesis were correct, a slightly shorter vibration period than that of C C'. It was formed of a square, with sides 75 centimetres in length, of copper wire 2 millimetres in diameter, and it was placed with its nearest side parallel to C B C', and at a distance of 30 centimetres from it. The sparking distance at the micrometer was then found to be 0·9 millimetre. When the terminals of the micrometer circuit were placed in contact with two metal spheres 8 centimetres in diameter, supported on insulating stands, the sparking distance could be increased up to 2·5 millimetres. When these were replaced by much larger spheres the sparking distance was diminished to a small fraction of a millimetre. Similar results were obtained on connecting the micrometer terminals with the plates of a Kohlrausch condenser. When the plates were far apart the increase of capacity increased the sparking distance, but when the plates were brought close together the sparking distances again fell to a very small value.

The simplest method of adjusting the capacity of the micrometer circuit is to suspend to its ends two parallel wires, the distance and lengths of which are capable of variation. By this means the author succeeded in increasing the sparking distance up to three millimetres, after which it diminished when the wires were either lengthened or shortened. The decrease of the sparking distance on increasing the capacity was naturally to be expected, but it would be difficult to understand, except on the principle of resonance, why a decrease of the capacity should have the same effect.

The experiments were then varied by diminishing the capacity of the circuit C B C' so as to shorten its period of oscillation, and the results confirmed those previously obtained, and a series of experiments in which the lengths and capacities of the circuits were varied in different ways, showed conclusively that the maximum effect does not depend on the conditions of either one of the two circuits, but on the existence of the proper relation between them.

When the two circuits were brought very close together and the discharger knobs separated by an interval of 7 millimetres, sparks were obtained at the micrometer, which were also 7 millimetres in length, when the two circuits had been carefully adjusted to have the same period. The induced E.M.F.s must in this case have attained nearly as high a value as the inducing ones.

To show the effect of varying the coefficient of self induction, a series of rectangles, *a b c d* (Fig. 4), were taken, having a constant breadth, *a b*, but a length, *a c*, continually increasing from 10 centimetres up to 250 centimetres. It was found that the maximum effect was obtained with a length of 1·8 metres. The quantitative results of these experiments are shown in Fig. 5, in which the abscissæ of the curve are the double lengths of the rectangles, and the ordinates represent the corre

* *See* Oberbeck, Wiedemann's *Annalen*, Vol. XXVI., p. 345, 1885.

sponding maximum sparking distances. The sparking distances could not be determined with great exactness, but the errors were not sufficient to mask the general nature of the result.

In a second series of experiments the sides $a c$ and $b d$ were formed of loose coils of wire which were gradually pulled out, and the result is shown in Fig. 6. It will be seen that the maximum sparking distance was attained for a somewhat greater length of side, which is explained by the fact that in the latter experiments the self-induction only was increased by increase of length, while in the former series the capacity was increased as well. Varying the resistance of the micrometer circuit by using copper and German silver wires of various diameters was found to have no effect on the period of oscillation, and extremely little on the sparking distance.

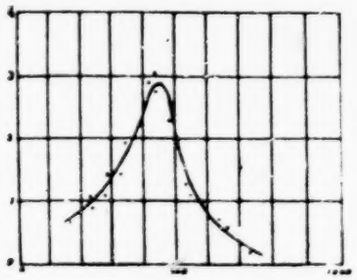

Fig. 5.

Curve showing relation between length of side of rectangle (taken as abscissa) and maximum sparking distance (taken as ordinate), the sides consisting of straight wires of varying lengths.

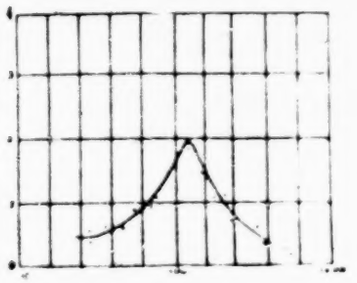

Fig. 6.

Curve showing relation between length of side of rectangle (taken as abscissa) and maximum sparking distance (taken as ordinate), the sides consisting of spirals gradually drawn out.

When the wire $c d$ was surrounded by an iron tube, or when it was replaced by an iron wire, no perceptible effect was obtained, confirming the conclusion previously arrived at that the magnetism of the iron is unable to follow such rapid oscillations, and therefore exerts no appreciable effect.

(To be continued.)

DYNAMOS WITHOUT COMMUTATORS OR BRUSHES.

BY TH. MARCHER (OF MÜLHEIM).

The first recorded attempt to construct a continuous-current dynamo without the impediments of commutator and brushes is due to M. A. F. Gravier, who took out a patent in France for a dynamo of this class. In 1882 a Mr. E. Newton obtained a similar patent in England. In 1883 L. Hajnis, of Prague, took out a patent in Germany for a dynamo on this principle; but in which some of the defects of the Gravier machine were avoided. In 1887 the Cronstadt Electrical Manufacturing Company also designed a dynamo without commutators. Since then but little seems to have been done in this direction.

I will, in the first place, briefly describe the original Gravier machine, from which he subsequently developed the non-commutator type. In Fig. 1 N and S are the field magnets; $a a a$ and $b b b$ are the armature coils, which are mounted on radial cores, as in the Lontin type; and $+f$ and $-f$ are the brushes. When the armature revolves in the direction shown by the large arrow currents are induced in the coils in the direction shown by the small arrows. The armature poles $a a a$, therefore, become S magnetised, and the poles $b b b$ N magnetised. Now imagine a second armature of the ring type, interposed between the above mentioned armature and the poles N S, this second armature having no coils at A A and B B (Fig. 2). The magnets $a a a$ will produce in this armature a current flowing in the direction $c c$, and the magnets

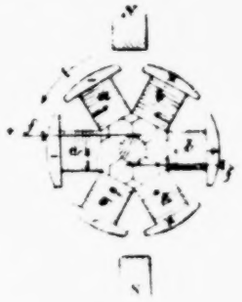

Fig. 1.

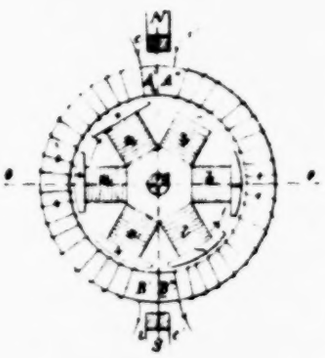

Fig. 2.

$b b b$ will produce a current flowing in the reverse direction, $f f$. Now, these two currents induce poles at A A and B B similar to those of the field-magnets, N S, at the adjacent points. If, therefore, sufficient residual magnetism was present, the magnet N S could be dispensed with, and the pole A A and B B would suffice. Gravier, however, was unable to get any good results from this form of machine, and subsequently designed one without commutator, collector, or brushes. In this dynamo (Fig. 3) Gravier had a revolving armature i, a revolving system of magnetisation, N S, a fixed armature I I, and a fixed system of magnetisation $a a$. The theoretical outcome of this arrangement is as follows:—The magnets $a a$ induce currents in i, which excite the magnets N S, which in turn induce currents in I I; the current thus obtained passes into the external circuit, and also round the magnets $a a$. One method of winding is shown in Fig. 4. The Hajnis machine consists of the same four essential parts, namely, fixed armature and field-magnets, and revolving armature and field magnets, the revolving parts being mounted on the same shaft. This arrangement is shown diagrammatically in Fig. 5. M M M M are fixed magnets, A A are revolving armature coils, B B B B are revolving magnets, and P P is the fixed ring armature. From each individual coil of the revolving armature connections are made to the corresponding magnet coil, each armature coil being one behind the

3587

[illegible] to the *static hysteresis* experiments by Prof. [illegible] and others also indicate the existence of *viscous* [illegible]. There is evidence of a true *time lag* in magnetisation, especially in the earlier stages of magnetisation. Iron requires time for a given magnetising force to produce its full effect, and this sluggishness does not appear explicable as due either of induction in the iron or to self induction in the magnetising circuit. The result of this magnetic viscosity is to augment the value of $-\int \mathrm{I}\,d\mathrm{H}$ in any rapidly performed cycle, and, consequently, to increase the dissipation of energy per cycle. When we come to consider the question of induction-transformers it will be seen that this viscous hysteresis has to be taken into account in establishing the full theory.

With respect to this *time lag* of magnetisation Prof. Ewing says:* "I repeatedly observed that when the magnetising current was applied to long wires of soft iron there was a distinct *creep up* of the magnetometer deflection after the current had attained a steady value."†

If this is so it would seem that a sufficiently rapid reversal of magnetising force would render such force inoperative in magnetising the iron. Just as the self induction of a circuit operates to make a certain delay in the appearance of the current corresponding to the application of a given electromotive force, and hence renders a circuit apparently a worse conductor for rapidly reversed electromotive forces, so the magnetic lag would introduce a sort of *magnetic self-induction* or retardation in the appearance of the magnetisation corresponding to a given magnetising force.

This time lag appears to be most manifest in the softest iron, and to be especially noticeable near the beginning of the steep part of the magnetisation curve.

In an investigation on the magnetisation of iron under feeble magnetic forces, Lord Rayleigh has also drawn attention to the fact that the settling down of iron when very soft or annealed into a new magnetic state is far from instantaneous;‡ the strength of the earth's horizontal magnetic field is called *h*, and Lord Rayleigh has shown that for unannealed iron and steel magnetising forces ranging from $\frac{1}{3}h$ to $\frac{1}{10800}h$ call forth proportional magnetisation. In other words, the susceptibility is constant over this range, and the value of the corresponding permeability is from 90 to 100, and that this small proportional magnetisation takes place independently of what may be the actual magnetisation of the iron provided it is not very near the condition usually called saturation.

The moment, however, that the magnetising force is pushed beyond these limits the phenomena of hysteresis and retentiveness make their appearance. According to Prof. Ewing (*loc. cit.*) the following group or constellation of hypotheses has to be made in order to approximate to a mechanical explanation of the magnetisation of iron:

1. An elastic tendency on the part of the magnetic molecules to recover their primitive position when displaced.
2. A static frictional resistance to their displacement and to their return removable largely by vibration.
3. A limit for each such that if the displacement of the molecule exceeds it a permanent displacement not removable by vibration results.
4. Probably a viscous resistance to the displacement and return of the molecules.
5. An unequal distribution amongst the molecules of the frictional resistance, such that in some of the molecules it is, perhaps, very small.

Aided by these suppositions we might proceed to build up, in imagination, a mechanical model, which should imitate, under the application of certain stresses, the behaviour of iron under magnetising force, but it is certain that the result would not be practically of much value; and it must still be left to future research to collect and analyse the necessary facts before the mystery of the magnetisation of iron is fully unraveled.

* *Phil. Trans.*, Part II., 1885, p. 523.

† See also Mr. T. Blakesley "On Magnetic Lag," *Phil. Mag.*, July, 1888, p. 34, in which it is shown that, by means of three dynamometers, the lag due to viscous hysteresis may be measured.

HERTZ'S RESEARCHES ON ELECTRICAL OSCILLATIONS.

BY G. W. DE TUNZELMANN, B.Sc.

H. Hertz has been engaged for some time past in a series of researches on electrical oscillations, which have led to results of very exceptional interest, as was pointed out by Prof. Fitzgerald in his inaugural address to Section A of the British Association last week; and as these results throw considerable light on the nature of electrical action, it will be of interest to readers of *The Electrician* to have a connected account of the investigations, to which I therefore propose to devote a short series of papers.

In Hertz's first Paper on the subject, viz., "On Very Rapid Electrical Oscillations" (Wied. *Ann.*, Vol. XXXI., page [illegible], 1887), he refers to a Paper by Colley, "On some New Methods for Observing Electrical Oscillations, with Applications" (*ibid.*, Vol. XXVI., page 432), who calls attention to the fact that Sir William Thomson in 1853 first showed the possibility of producing electrical oscillations by the discharge of a charged conductor, and gives references to all the investigations in the same direction which were known to him.

For the benefit of readers who may wish to pursue the subject further the list is reproduced below:—

According to these investigations, the electrical oscillations produced in an open circuit by means of an induction coil are measured by ten thousandths of a second, while in the case of the oscillatory discharge of a Leyden jar they are about a hundred times as rapid, as was shown by Feddersen.

According to theory, still more rapid oscillations should be possible in an open circuit of wire of good conducting material, provided its ends are not connected with conductors of any considerable capacity; but it is not possible to determine from theory whether measurable oscillations are actually produced. Some observations of Hertz's led him to believe that under certain circumstances oscillations of this kind were produced, and his researches show that this is so, and that the oscillations are about a hundred times as rapid as those observed by Feddersen; so that their periods are measured by hundred millionths of a second, and, therefore, they occupy a position intermediate between acoustic and luminous vibrations.

Preliminary Experiments.—It is known that if in the secondary circuit of an induction coil there be inserted, in addition to the ordinary air space, across which sparks pass, a Riess spark micrometer, with its poles joined by a long wire,

the discharge will pass across the air space of the micrometer in preference to following the path of least resistance through the wire, provided this air space does not exceed a certain limit, and it is upon this principle that lightning protectors for telegraph lines are constructed. It might be expected that the sparks could be made to disappear by diminishing the length and resistance of the connecting wire; but Hertz finds that though the length of the sparks can be diminished in this way, it is almost impossible to get rid of them entirely, and they can still be observed when the balls of the micrometer are connected by a thick copper wire only a few centimetres in length.

This shows that there must be variations in the potential measureable in hundredths of a volt in a portion of the circuit only a few centimetres in length, and it also gives an indirect proof of the enormous rapidity of the discharge, for the difference of potential between the micrometer knobs can only be due to self-induction in the connecting wire. Now the time occupied by variations in the potential of one of the knobs must be of the same order as that in which these variations can be transmitted through a short length of a good conductor to the second knob. The resistance of the wire connecting the knobs is found to be without sensible effect on the results.

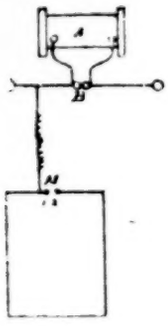

FIG. 1.

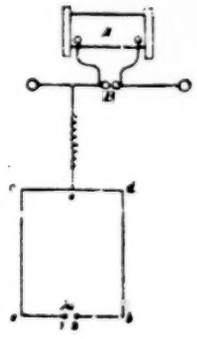

FIG. 2.

In Fig. 1, A is an induction coil and B a discharger. The wire connecting the knobs 1 and 2 of the spark micrometer M, consists of a rectangle, half a metre in length, of copper wire 2 millimetres in diameter. This rectangle is connected with the secondary circuit of the coil in the manner shown in the diagram, and when the coil is in action sparks, sometimes several millimetres in length, are seen to pass between the knobs 1 and 2, showing that there are violent electrical oscillations, not only in the secondary circuit itself, but in any conductor in contact with it. This experiment shows even more clearly than the previous one that the rapidity of the oscillations is comparable with the velocity of transmission of electrical disturbances through the copper wire, which according to all the evidence at our disposal is nearly equal to the velocity of light.

In order to obtain micrometer sparks some millimetres in length, a powerful induction coil is required, and the one used by Hertz was 52 centimetres in length and 20 centimetres in diameter, provided with a mercury contact breaker, and excited by six large Bunsen cells. The discharger terminals consisted of brass knobs 3 centimetres in diameter. The experiments showed that the phenomenon depends to a very great extent on the nature of the sparks at the discharger, the micrometer sparks being found to be much weaker when the discharge in the secondary circuit took place between two points, or between a point and a plate, than when knobs were used. The micrometer sparks were also found to be greatly enfeebled when the secondary discharge took place in a rarefied gas, and also when the sparks in the secondary were less than half a centimetre in length, while, on the other hand, if they exceeded 1½ centimetres the sparks could no longer be observed between the micrometer knobs. The length of secondary spark which was found to give the best results, and which was, therefore, employed in the further observations, was about three quarters of a centimetre.

Very slight differences in the nature of the secondary sparks were found to have great effect on those at the micrometer, and Hertz states that after some practice he was able to determine at once from the sound and appearance of the secondary spark whether it was of a kind to give the most powerful effects at the micrometer. The sparks which gave the best results were of a brilliant white colour, only slightly jagged, and accompanied by a sharp crack.

The influence of the spark is readily shown by increasing the distance between the discharger knobs beyond the striking distance, when the micrometer sparks disappear entirely, although the variations of potential are now greater than before. The length of the micrometer circuit has naturally an important influence on the length of the spark, as the greater its length the greater will be the retardation of the electrical wave in its passage through it from one knob of the micrometer to the other.

The material, the resistance, and the diameter of the wire of which the micrometer circuit is formed have very little influence on the spark. The potential variations cannot, therefore, be due to the resistance, and this was to be expected, for the rate of propagation of an electrical disturbance along a conductor depends mainly on its capacity and coefficient of self-induction, and only to a very small extent on its resistance. The length of the wire connecting the micrometer circuit with the secondary circuit of the coil is also found to have very little influence, provided it does not exceed a few metres in length. The electrical disturbances must therefore traverse it without undergoing any appreciable change. The position of the point of the micrometer circuit which is joined to the secondary circuit is, on the other hand, of the greatest importance, as would be expected, for if the point is placed symmetrically with respect to the two micrometer knobs the variations of potential will reach the latter in the same phase, and there will be no effect, as is verified by observation. If the two branches of the micrometer circuit on each side of the point of contact of the connection with the secondary are not symmetrical, the spark cannot be made to disappear entirely; but a minimum effect is obtained when the point of contact is about half-way between the micrometer knobs. This point may be called the null point.

Fig. 2 shows the arrangement employed, *e* being the null point of the rectangular circuit, which is 125 centimetres long by 80 centimetres broad. When the point of contact is at *a* or *b*, sparks of from 3 to 4 milimetres in length are observed; when it is at *e* no sparks are seen; but they can be made to reappear by shifting the point of contact a few centimetres to the right or left of the null point. It should be noted that sparks only a few hundredths of a milimetre in length can be observed. If when the point of contact is at *e* another conductor is placed in contact with one of the micrometer knobs the sparks reappear.

Now, the addition of this conductor cannot produce any alteration in the time taken by the disturbances proceeding from *e* to reach the knobs, and, therefore, the phenomenon cannot be due simply to single waves in the directions *ea* and *eb* respectively, but must be due to repeated reflection of the waves until a condition of stationary vibration is attained, and the addition of the conductor to one of the knobs must diminish or prevent the reflection of the waves from that terminal. It must be assumed, then, that definite oscillations are set up in the micrometer circuit just as an elastic bar is thrown into definite vibrations by blows from a hammer. If this assumption is correct, the condition for the disappearance of the sparks at M will be that the vibration periods of the two branches *e*1 and *e*2 shall be equal. These periods are determined by the products of the coefficients of self induction of these conductors into the capacities of their terminals, and are practically independent of their resistances.

In confirmation of this, it is found that if when the point of contact is at *e* and the sparks have been made to reappear by connecting a conductor with one of the knobs, this conductor is replaced by one of greater capacity, the sparking is greatly increased. If a conductor of equal capacity, is connected with

3589

...other micrometer knob the sparks disappear again; the ... of the first conductor can also be counteracted by shifting the point of contact towards it, thereby diminishing the ... in that branch. The conclusions were further confirmed by the results obtained when coils of copper wire were inserted into one or other, and then into both of the ... of the micrometer circuit.

... supposed that as the self induction of iron wires is, for ... alternations, from eight to ten times that of copper wires, ... short iron wire would balance a long copper one; ... was not found to be the case, and he concludes that, ... the great rapidity of the alternations, the magnetism of ... is unable to follow them, and therefore has no effect on ... self induction.

(To be continued.)

MANUFACTURE OF LIGHT.*

BY DR. OLIVER LODGE, F.R.S.

The conclusions at which we have arrived, that light is an ... disturbance, and that light waves are excited by ... oscillations, must ultimately, and very shortly, have a ... import.

Our present systems of making light artificially are wasteful and ineffective. We want a certain range of oscillation, be... 7,000 and 4,000 billion vibrations per second; no other ... to us, because no other has any effect on our retina. ... we do not know how to produce vibrations of this rate. We can produce a definite vibration of one or two hundred ... thousand per second, in other words, we can excite a ... tone of definite pitch, and we can command any de... ... range of such tones continuously by means of bellows ... a key board. We can also (though the fact is less well ... we) excite momentarily definite ethereal vibrations of some ... millions per second, as I have at length explained; but we ... not at present seem to know how to maintain this rate quite ... To get much faster rates of vibration than this ... have to fall back upon atoms. We know how to make ... vibrate; it is done by what we call "heating" the sub..., and if we could deal with individual atoms unhampered ... others, it is possible that we might get a pure and simple ... of vibration from them. It is possible, but unlikely, for ... even when isolated, have a multitude of modes of vibra... ... to themselves, of which only a few are of practical ... to us, and we do not know how to excite some without also ... others. However, we do not at present even deal with in... ... atoms; we treat them crowded together in a compact ... so that their modes of vibration are really infinite.

... a lump of matter, say a carbon filament or a piece ... stone, and by raising its temperature we impress upon ... higher and higher modes of vibration, not trans... the lower into the higher, but superposing the higher ... the lower, until at length we get such rates of vibration ... retina is constructed for, and we are satisfied. But how ... and indirect and empirical is the process. We want ... range of rapid vibrations, and we know no better than ... the whole series leading up to them. It is as though, ... order to sound some little shrill octave of pipes in an organ, ... were obliged to depress every key and every pedal, and to ... a young hurricane.

I have purposely selected as examples the more perfect ... of obtaining artificial light, wherein the waste radia... ... only useless, and not noxious. But the old fashioned ... was cruder even than this; it consisted simply in setting ... burning, whereby not only the fuel but the air ... consumed, whereby also a most powerful radiation was ... in the waste waves of which we were content to sit ... for the sake of the minute, almost infinitesimal, frac... ... of it which enabled us to see.

Everyone knows now, however, that combustion is not a ... or healthy mode of obtaining light; but everybody does not realise that neither is incandescence a satisfactory and unwasteful method which is likely to be practised for more than a few decades, or perhaps a century.

Look at the furnaces and boilers of a great steam engine driving a group of dynamos, and estimate the energy expended; and then look at the incandescent filaments of the lamps excited by them, and estimate how much of their radiated energy is of real service to the eye. It will be as the energy of a pitch pipe to an entire orchestra.

It is not too much to say that a boy turning a handle could, if his energy were properly directed, produce quite as much real light as is produced by all this mass of mechanism and consumption of material.

There might, perhaps, be something contrary to the laws of Nature in thus hoping to get and utilise some specific kind of radiation without the rest; but Lord Rayleigh has shown in a short communication to the British Association at York* that it is not so, and that therefore we have a right to try to do it.

We do not yet know how it is true, but it is one of the things we have got to learn.

Anyone looking at a common glow worm must be struck with the fact that not by ordinary combustion, nor yet on the steam engine and dynamo principle, is that easy light produced. Very little waste radiation is there from phosphorescent things in general. Light of the kind able to affect the retina is directly emitted, and for this, for even a large supply of this, a modicum of energy suffices.

Solar radiation consists of waves of all sizes, it is true, but then solar radiation has innumerable things to do besides making things visible. The whole of its energy is useful. In artificial lighting nothing but light is desired. When heat is wanted it is best obtained separately, by combustion. And so soon as we clearly recognise that light is an electrical vibration, so soon shall we begin to look about for some mode of exciting and maintaining an electrical vibration of any required degree of rapidity. When this has been accomplished, the problem of artificial lighting will have been solved.

ON RECENT DEVELOPMENTS OF THE COWLES' ALUMINIUM PROCESS.†

BY R. E. CROMPTON.

It is unnecessary to again describe the earlier stages of the Brothers Cowles invention of the electric furnace. I confine myself to a description of such parts of the new plant which has been recently put down at Milton, near Stoke upon Trent, that I think will be of general scientific interest.

The experience in America at the works at Lockport, Ohio, showed conclusively that great economies were to be expected from increasing the size of the furnaces and the strength of the electric currents employed to work them; but no current larger than 3,000 amperes had been used up to the time that the Milton Works were planned.

Mr. Eugene Cowles came over to England to ascertain whether English makers of dynamo machines were prepared to supply one 60 per cent. larger than Mr. Brush's "Colossus," which had been made specially for them in America, and which was then the largest direct current machine in the world. He prepared his specification for a dynamo to give a current of 5,000 amperes at 60 volts, and eventually Messrs. Crompton's designs and tender were accepted.

The works were built near the Milton Station on the North Staffordshire Railway, the boilers for generating the steam required are of the Babcock-Wilcox type, and are provided with mechanical stokers; the steam engine is of 600 horse-power, and is a compound condensing horizontal tandem, made by Messrs. Pollit and Wigzel, of Sowerby Bridge; it is furnished with an exceedingly perfect centrifugal governor, which maintains the speed accurately at seventy six revolutions in spite of very great fluctuations in the load. The electrical

UNITED STATES PATENT OFFICE.

MICHAEL I. PUPIN, OF NEW YORK, N. Y.

ELECTRICAL TRANSMISSION BY RESONANCE-CIRCUITS.

SPECIFICATION forming part of Letters Patent No. 640,516, dated January 2, 1900.

Application filed May 28, 1895. Renewed October 14, 1899. Serial No. 733,890. (No model.)

To all whom it may concern:

Be it known that I, MICHAEL I. PUPIN, a citizen of the United States of America, residing in the city, county, and State of New York, have invented certain new and useful Improvements in Electrical Transmission by Resonance-Circuits, of which the following is a specification.

If a condenser be inserted in a line and a self-induction coil be connected in shunt with this condenser, then an alternating current impressed upon the line will under certain conditions be greater in the shunt-circuit than in the line itself. The shunt-circuit in this case may be considered as a step-up transformer of the line-current. This subject has been discussed at considerable length in Vol. I of Fleming's treatise on the alternate-current transformer and also in Blakesley's book on alternating currents. There have been, however, no experimental data to guide one in determining the exact limitations within which the results of pure theory are applicable. Such limitations exist, and unless they are clearly understood this method of step-up transformation indicated by the theory fails completely. I have studied experimentally this method of step-up current transformation and have discovered the necessary and sufficient conditions under which such a shunt-circuit is resonant. These conditions may be stated briefly, as follows:

First. The capacity of the condenser and the self-induction of the shunt-coil must be so related as to bring the shunt-circuit in resonance with the line-current.

Second. The shunt-coil should either contain no iron at all, or if it contains iron the quantity of it should be very small, and it should be well laminated and should not form a closed magnetic circuit. This is true of resonance-circuits of every form, it being a general principle and not one limited to shunt-circuits that the use of iron should be avoided in such circuits.

Third. The ohmic resistance of the shunt-circuit should be as small as possible and certainly smaller than the resistance of the line.

By employing a well-constructed condenser and a low-resistance self-induction coil without iron I have succeeded in obtaining from a given line-current a resonant current that is twenty times as large as the line-current. I believe that I am the first to investigate experimentally the behavior of such resonant shunt-circuits and to discover the conditions under which they will operate in a manner indicated by the theory. At any rate I consider myself to be the first to apply such circuits to the solution of the practical problem solved by the following invention.

In multiple telegraphy by resonance-circuit it is necessary to employ selective circuits at the receiving end of the line. The employment of resonance shunt-circuits for selective receiving-circuits offers many important advantages.

By a "resonance-circuit" is meant one which has self-induction and capacity and therefore a natural period. When the self-induction and capacity are properly adjusted so as to give it the period of the impressed electromotive force, the resonance-circuit becomes resonant to this electromotive force.

The arrangement of resonance shunt-circuits herein shown gives less self-induction at the receiving end of the line than any other form of resonance-circuit. They are also under all circumstances step-up transformers of the line-current and are less apt when rendered resonant to interfere with each other than resonance-circuits of any other form.

In the accompanying drawings, which form a part of this specification, Figure 1 is a diagrammatic view of the transmitter and receiver stations, the line-wire being broken away. Fig. 2 is a diagrammatic view of the receiver-station in a somewhat-modified system. Fig. 3 is another diagrammatic view of the receiver-station in another modified system.

Referring now more particularly to Fig. 1, $x\ y$ is a telegraph line grounded at its ends G and G'. At the sending end of the line two alternators A and B impress in the line $x\ y$ by means of the coils C D and E F two electromotive forces of different frequencies, say of one hundred and fifty and two hundred and fifty vibrations per second, respectively. The keys a and b serve to open and close the inducing alternator-circuits, and thus impart to the line alternating-current waves.

With a long line, such as is usually employed in telegraph systems of the general

3597

type here described, the two circuits A a C and B b E are practically independent of each other. They may be varied in arrangement and still retain essential independence. Two circuits forming parts of a system of electric conductors are independent of each other when the energy generated in one by the action of an electromotive force acting in the other is small in comparison with the energy generated in the whole system by the action of this same electromotive force. In order to secure this mutual independence in the transmitter-circuits, it is important that they should act upon the main line through elements which, like the coils D and F, are connected in the main line in series. In practice it is found advantageous to throw the currents onto the line at the transmitting end through transformers. And in case of lines that are short in comparison with the wave length of the current transmitted the selectivity of the receiving resonance-circuits is more pronounced and independent of what is going on at the transmitting end of the line when the secondary coils of the transformers at the transmitting end are all placed in series in the line than when they are placed in multiple. At the receiving end it is important to have condensers with shunts around them containing self-induction coils forming parts of the main line. It is obvious that the coils I and L are just as much in series in the main line as are the condensers H and K.

By the term "transmitter-circuits" I do not mean to designate transmitter branches connected to a line-wire in multiple with each other. Such branches, of course, cannot be independent of each other, since changes in the resistance and self-induction of one will appreciably affect the others.

At the receiving end condensers H and K, of adjustable capacity, are inserted in the line in series, and each condenser is shunted by a coil of adjustable self-induction containing no iron. These coils are indicated in Fig. 1 by the letters I and L. The capacity of the condenser H and the self-induction of the coil I being such that the natural period or frequency of the shunt or resonance circuit H I is the same as the period of one of the electromotive forces which produce the current coming over the line—say that having a periodicity of one hundred and fifty per second—this circuit H I will be in resonance with the current and therefore will act selectively with respect to it. In the same manner by adjusting the electromagnetic constants of the resonant shunt-circuit, which contains coil L, this resonance-circuit is made to act selectively with respect to the other current on the line. These resonance receiving-circuits are, like the transmitting-circuits, mutually independent, a current flowing in one generating no appreciable current in another. If, therefore, the periodicity of the electromotive force impressed by circuit A C a be one hundred and fifty and that of B E b be two hundred and fifty, we shall have, whenever the key a closes the circuit A C a, a resonant current of one hundred and fifty periods in the resonant shunt-circuit H I. Similarly when the key b closes the circuit B E b there will be a resonant current of two hundred and fifty periods in the local circuit K L. If both keys are closed simultaneously and therefore both alternators are acting simultaneously upon the line, there will be a resonant current with the frequency of one hundred and fifty in the circuit H I and there will be a resonant current with a frequency of two hundred and fifty in the circuit K L.

It is evident that theoretically any number of resonance shunt-circuits may be employed at the receiving end of the line, each made resonant (by a proper adjustment of its electromagnetic constants) to one of the periodic currents impressed on the line at the transmitting end.

Referring now more particularly to Fig. 2, which represents the receiving end of the line and can be attached onto the transmitting end shown in Fig. 1 instead of the receiving end shown in that figure, I show a resonance-circuit H I and K L. The condensers H and K, as in Fig. 1, are in series in the line; but I control the frequency of H I by means of a circuit H I I', which contains the secondary coil of the induction-coil I I and the supplemental condenser H and a self-induction coil I'. This system is in its practical operation the same as that of Fig. 1. In each the supplemental condenser H and K and the self-induction coil affect the constants of the resonant shunt-circuits, and by adjusting one or both the natural periods of the resonant shunt-circuits H I and K L can be adjusted until they equal the desired frequencies; but instead of indirectly affecting the constants of the resonant shunt-circuits by means of the supplemental condenser and induction-coils, as in Fig. 2, I can put the supplemental condensers directly in the resonant shunt-circuits. This is shown in Fig. 3, which, like Fig. 2, represents a modification of the receiving end shown in Fig. 1. The periodicities or frequencies of the induction-circuits H H' I and K k' L can be adjusted by adjusting the capacity of the supplemental condensers H and K and the self-induction coils I and L. The forms shown in Figs. 2 and 3 are preferable to the form shown in Fig. 1.

Each resonant shunt-circuit contains an electromagnet m or n, which may be taken as representing generically a translation device operated by the energy of the current which traverses the resonant shunt-circuit. It may be operated by this current either directly or indirectly. It is shown in Fig. 1 as operated directly since the translating device is included directly in the resonant shunt-circuit.

The disposition of the coils and condensers as shown in Figs. 2 and 3 does not differ in principle from that shown in Fig. 1, yet it

3156

should be noted here that my experience shows these dispositions to be more effective under certain conditions than that of Fig. 1. The dispositions give the resonant shunt-circuits a greater selectivity, and therefore I find these preferable in cases where a large number of resonant receiving-circuits are to be employed whose periods are near each other.

I do not claim in this application the method of distributing the electrical energy of periodic currents, which consists in throwing a number of such currents of different frequencies upon a single line and conveying the several energies of these currents each selectively to a separate electrical translating device; nor do I claim herein a system of distribution of electrical energy comprising a main line, means for impressing multiperiodic electromotive forces thereon, branch lines connected with the main line each having its self-induction and capacity so related as to be permeable to alternating currents of a given frequency, and an electrical receiving device in each branch line; nor do I broadly claim any method of or apparatus for distributing electromotive forces of different frequencies, each selectively, to a separate electrical translating device by the proper proportioning of the electromagnetic constants of the parts of the electrical system to be made selective and by which the translating devices are controlled either with or without any method of or arrangement of apparatus for developing upon a main line the electromotive forces of different desired frequencies independently of each other and simultaneously or otherwise, because these broad inventions are claimed substantially in my other application, Serial No. 501,092, filed February 23, 1894, for multiple telegraphy and which application is now involved in interference; nor do I broadly claim the combination, in an electric circuit, of means for imposing upon said circuit one or more electromotive forces of previously-selected periodicities, one or more circuits in inductive relation to said first-named circuit, and means for tuning the said inductively-related circuit or circuits each in resonance with one of said periodic electromotive forces and independently of the rest of the system, with or without additional means for also tuning separate branches connected to the first-named circuit, with which branches the other circuits named are inductively related, these being claimed in my other application for improvements in telegraphy, filed January 28, 1895, Serial No. 536,488, and at the transmitting-stations I prefer to use the arrangement shown and claimed in my other application for improvements in distributing electrical energy, filed May 21, 1895, Serial No. 550,058, renewed December 4, 1899, as Serial No. 739,207.

Where in the claims I specify the combination of a line-wire or a line with one or more resonant circuits without indicating that there are both receiving and transmitting circuits connected by a line-wire, I wish it to be distinctly understood that I do not limit myself to any specific means or method of transmitting from one station to another nor to any specific connection between the transmitting and receiving stations; nor do I intend, except where it is specified in the claims, to indicate definitely the arrangement which should be employed at the transmitting-station or to limit the claims with respect thereto.

It is obvious that many modifications may be made in my arrangement without departing from the spirit of my invention.

Having now fully described my invention, what I claim, and desire to secure by Letters Patent of the United States, is—

1. In an electric system the combination of a main line, mutually-independent exciting-circuits, which act upon the main line through elements placed therein in series, independent means for impressing an electromotive force of desired frequency upon the main line at each exciting circuit, mutually-independent receiving-circuits, means for tuning each receiving circuit to resonance with one of the impressed electromotive forces, and translating devices operated by the currents in the receiving circuits, substantially as described.

2. In an electric system the combination of a main line, mutually-independent exciting-circuits which act upon the main line through elements placed therein in series, independent means for impressing an electromotive force of desired frequency upon the main line at each exciting-circuit, mutually-independent receiving circuits which are acted upon from the main line through elements connected therein in series, means for tuning each receiving-circuit to resonance with one of the impressed electromotive forces, and translating devices operated by the currents in the receiving circuits, substantially as described.

3. In an electric system the combination of a main line, mutually independent exciting-circuits which act upon the main line through transformers the secondary coils of which are placed in the main line in series, independent means for impressing an electromotive force of desired frequency upon the main line at each exciting-circuit, condensers in series in the main line, a shunt around each condenser containing a self induction coil, thus forming mutually-independent receiving circuits, means for tuning each receiving-circuit to one of the impressed electromotive forces, and translating devices operated by the currents in the receiving-circuits, substantially as described.

4. In an electrical system, the combination of a line-wire, a condenser therein, a shunt around the condenser containing a self-induction coil without an iron core thus forming a resonance circuit and means for adjusting the electromagnetic constants of the resonance-circuit so as to give it a desired periodicity, substantially as described.

5. In a multiplex signaling system the com-

bination of line-wire, means for impressing thereon, independently of each other, electromotive forces of two or more distinct periodicities, two or more condensers in series in the line; a shunt around each condenser containing a self-induction coil, each condenser with its shunt-coil forming an independent resonance-circuit, receiving instruments therein, and means for adjusting the electromagnetic constants of these resonance-circuits, so as to give to each such circuit a periodicity corresponding to one of the impressed electromotive forces, substantially as described.

6. In an electrical system, the combination of a line-wire, means for impressing thereon a current of a given frequency, a condenser in the line, a shunt around the condenser containing a self-induction coil without an iron core thus forming a resonance-circuit, and means for adjusting the electromagnetic constants of the resonance-circuit so as to give it a periodicity corresponding with the frequency of the current to be impressed upon the line, substantially as described.

7. In an electrical system, the combination of the line, means for impressing thereon a current produced by two or more electromotive forces of different frequencies which are independent of each other, two or more condensers in the line in series, a shunt around each condenser containing a self-induction coil, thus forming resonance-circuits, circuits in inductive relation thereto and containing condensers and self-induction coils supplemental to those of the resonance-circuits, receiving instruments, and means for adjusting the electromagnetic constants of these resonance-circuits so as to give each such circuit a periodicity corresponding to the frequency of one of the electromotive forces impressed upon the line, substantially as described.

8. In an electrical system, the combination of a line-wire, two or more condensers connected in series therein, a shunt around each condenser containing a self-induction coil, thus forming resonance-circuits, receiving instruments therein, a supplemental condenser in each of the resonance-circuits, and means for adjusting the constants of each resonance-circuit, so as to give it a desired periodicity, substantially as described.

9. In an electrical system, the combination of a line-wire, means for impressing thereon a current produced by two or more electromotive forces of different desired frequencies, two or more condensers in the line in series, a shunt around each condenser containing a self-induction coil, thus forming resonance-circuits, means for adjusting the constants of each resonance-circuit so as to give each a periodicity corresponding to the frequency of one of the electromotive forces, and translating devices each operated by the energy of the current traversing one of the resonance-circuits, substantially as described.

10. A resonance-circuit in which the self-induction coil employed to give the circuit a definite periodicity contains no iron, substantially as described.

Signed in New York this 25th day of May, 1895.

UNITED STATES PATENT OFFICE.

NIKOLA TESLA, OF NEW YORK, N. Y.

SYSTEM OF TRANSMISSION OF ELECTRICAL ENERGY.

SPECIFICATION forming part of Letters Patent No. 645,576, dated March 20, 1900

Application filed September 2, 1897. Serial No. 650,343. (No model.)

To all whom it may concern:

Be it known that I, NIKOLA TESLA, a citizen of the United States, residing at New York, in the county and State of New York, have invented certain new and useful Improvements in Systems of Transmission of Electrical Energy, of which the following is a specification, reference being had to the drawing accompanying and forming a part of the same.

It has been well known heretofore that by rarefying the air inclosed in a vessel its insulating properties are impaired to such an extent that it becomes what may be considered as a true conductor, although one of admittedly very high resistance. The practical information in this regard has been derived from observations necessarily limited in their scope by the character of the apparatus or means heretofore known and the quality of the electrical effects producible thereby. Thus it has been shown by William Crookes in his classical researches, which have so far served as the chief source of knowledge of this subject, that all gases behave as excellent insulators until rarefied to a point corresponding to a barometric pressure of about seventy-five millimeters, and even at this very low pressure the discharge of a high-tension induction-coil passes through only a part of the attenuated gas in the form of a luminous thread or arc, a still further and considerable diminution of the pressure being required to render the entire mass of the gas inclosed in a vessel conducting. While this is true in every particular so long as electromotive or current impulses such as are obtainable with ordinary forms of apparatus are employed, I have found that neither the general behavior of the gases nor the known relations between electrical conductivity and barometric pressure are in conformity with these observations when impulses are used such as are producible by methods and apparatus devised by me and which have peculiar and hitherto unobserved properties and are of effective electromotive forces, measuring many hundred thousands or millions of volts. Through the continuous perfection of these methods and apparatus and the investigation of the actions of these current impulses I have been led to the discovery of certain highly-important and useful facts which have hitherto been unknown. Among these and bearing directly upon the subject of my present application are the following: First, that atmospheric or other gases, even under normal pressure, when they are known to behave as perfect insulators, are in a large measure deprived of their dielectric properties by being subjected to the influence of electromotive impulses of the character and magnitude I have referred to and assume conducting and other qualities which have been so far observed only in gases greatly attenuated or heated to a high temperature, and, second, that the conductivity imparted to the air or gases increases very rapidly both with the augmentation of the applied electrical pressure and with the degree of rarefaction, the law in this latter respect being, however, quite different from that heretofore established. In illustration of these facts a few observations, which I have made with apparatus devised for the purposes here contemplated, may be cited. For example, a conductor or terminal, to which impulses such as these here considered are supplied, but which is otherwise insulated in space and is remote from any conducting-bodies, is surrounded by a luminous flame-like brush or discharge often covering many hundreds or even as much as several thousands of square feet of surface, this striking phenomenon clearly attesting the high degree of conductivity which the atmosphere attains under the influence of the immence electrical stresses to which it is subjected. This influence is, however, not confined to that portion of the atmosphere which is discernible by the eye as luminous and which, as has been the case in some instances actually observed, may fill the space within a spherical or cylindrical envelop of a diameter of sixty feet or more, but reaches out to far remote regions, the insulating qualities of the air being, as I have ascertained, still sensibly impaired at a distance many hundred times that through which the luminous discharge projects from the terminal and in all probability much farther. The distance extends with the increase of the electromotive force of the impulses, with the diminution of the density of the atmosphere, with the elevation of the active terminal above the ground, and also, apparently, in a slight measure, with the degree of moisture contained in

3163

the air. I have likewise observed that this region of decidedly noticeable influence continuously enlarges as time goes on, and the discharge is allowed to pass not unlike a conflagration which slowly spreads, this being possibly due to the gradual electrification or ionization of the air or to the formation of less insulating gaseous compounds. It is, furthermore, a fact that such discharges of extreme tensions approximating those of lightning, manifest a marked tendency to pass upward freely from the ground, which may be due to electrostatic repulsion, or possibly to slight heating and consequent rising of the electrified or ionized air. These latter observations make it appear probable that a discharge of this character allowed to escape into the atmosphere from a terminal maintained at a great height will gradually leak through and establish a good conducting path to more elevated and better conducting air strata, a process which possibly takes place in silent lightning discharges frequently witnessed on hot and sultry days. It will be apparent to what an extent the conductivity imparted to the air is enhanced by the increase of the electromotive force of the impulses when it is stated that in some instances the area covered by the flame discharge mentioned was enlarged more than sixfold by an augmentation of the electrical pressure, amounting scarcely to more than fifty per cent. As to the influence of rarefaction upon the electric conductivity imparted to the gases it is noteworthy that, whereas the atmospheric or other gases begin ordinarily to manifest this quality at something like seventy-five millimeters barometric pressure with the impulses of excessive electromotive force to which I have referred, the conductivity, as already pointed out, begins even at normal pressure and continuously increases with the degree of tenuity of the gas, so that at, say, one hundred and thirty millimeters pressure, when the gases are known to be still nearly perfect insulators for ordinary electromotive forces, they behave toward electromotive impulses of several millions of volts like excellent conductors, as though they were rarefied to a much higher degree. By the discovery of these facts and the perfection of means for producing in a safe, economical, and thoroughly practicable manner current impulses of the character described it becomes possible to transmit through easily-accessible and only moderately rarefied strata of the atmosphere electrical energy not merely in insignificant quantities, such as are suitable for the operation of delicate instruments and like purposes, but also in quantities suitable for industrial uses on a large scale up to practically any amount and, according to all the experimental evidence I have obtained, to any terrestrial distance. To conduce to a better understanding of this method of transmission of energy and to distinguish it clearly, both in its theoretical aspect and in its practical bearing, from other known modes of transmission, it is useful to state that all previous efforts made by myself and others for transmitting electrical energy to a distance without the use of metallic conductors, chiefly with the object of actuating sensitive receivers, have been based, in so far as the atmosphere is concerned, upon those qualities which it possesses by virtue of its being an excellent insulator, and all these attempts would have been obviously recognized as ineffective if not entirely futile in the presence of a conducting atmosphere or medium. The utilization of any conducting properties of the air for purposes of transmission of energy has been hitherto out of the question in the absence of apparatus suitable for meeting the many and difficult requirements, although it has long been known or surmised that atmospheric strata at great altitudes—say fifteen or more miles above sea-level—are, or should be, in a measure, conducting, but assuming even that the indispensable means should have been produced then still a difficulty, which in the present state of the mechanical arts must be considered as insuperable, would remain—namely, that of maintaining terminals at elevations of fifteen miles or more above the level of the sea. Through my discoveries before mentioned and the production of adequate means the necessity of maintaining terminals at such inaccessible altitudes is obviated and a practical method and system of transmission of energy through the natural media is afforded essentially different from all those available up to the present time and possessing, moreover, this important practical advantage, that whereas in all such methods or systems heretofore used or proposed but a minute fraction of the total energy expended by the generator or transmitter was recoverable in a distant receiving apparatus by my method and appliances it is possible to utilize by far the greater portion of the energy of the source and in any locality however remote from the same.

Expressed briefly, my present invention, based upon these discoveries, consists then in producing at one point an electrical pressure of such character and magnitude as to cause thereby a current to traverse elevated strata of the air between the point of generation and a distant point at which the energy is to be received and utilized.

In the accompanying drawing a general arrangement of apparatus is diagrammatically illustrated such as I contemplate employing in the carrying out of my invention on an industrial scale—as, for instance, for lighting distant cities or districts from places where cheap power is obtainable.

Referring to the drawing, A is a coil, generally of many turns and of a very large diameter, wound in spiral form either about a magnetic core or not, as may be found necessary. C is a second coil, formed of a conductor of much larger section and smaller

length, wound around and in proximity to the coil A. In the transmitting apparatus the coil A constitutes the high-tension secondary and the coil C the primary, of much lower tension of a transformer. In the circuit of the primary C is included a suitable source of current G. One terminal of the secondary A is at the center of the spiral coil, and from this terminal the current is led by a conductor B to a terminal D, preferably of large surface, formed or maintained by such means as a balloon at an elevation suitable for the purposes of transmission, as before described. The other terminal of the secondary A is connected to earth and, if desired, also to the primary in order that the latter may be at substantially the same potential as the adjacent portions of the secondary, thus insuring safety. At the receiving-station a transformer of similar construction is employed, but in this case the coil A, of relatively thin wire, constitutes the primary and the coil C, of thick wire or cable, the secondary of the transformer. In the circuit of the latter are included lamps L, motors M, or other devices for utilizing the current. The elevated terminal D is connected with the center of the coil A, and the other terminal of said coil is connected to earth and preferably, also, to the coil C for the reasons above stated.

It will be observed that in coils of the character described the potential gradually increases with the number of turns toward the center, and the difference of potential between the adjacent turns being comparatively small a very high potential, impracticable with ordinary coils, may be successfully obtained. It will be, furthermore, noted that no matter to what an extent the coils may be modified in design and construction, owing to their general arrangement and manner of connection, as illustrated, those portions of the wire or apparatus which are highly charged will be out of reach, while those parts of the same which are liable to be approached, touched, or handled will be at or nearly the same potential as the adjacent portions of the ground, this insuring, both in the transmitting and receiving apparatus and regardless of the magnitude of the electrical pressure used, perfect personal safety, which is best evidenced by the fact that although such extreme pressures of many millions of volts have been for a number of years continuously experimented with no injury has been sustained neither by myself or any of my assistants.

The length of the thin-wire coil in each transformer should be approximately one-quarter of the wave length of the electric disturbance in the circuit, this estimate being based on the velocity of propagation of the disturbance through the coil itself and the circuit with which it is designed to be used. By way of illustration if the rate at which the current traverses the circuit, including the coil, be one hundred and eighty-five thousand miles per second then a frequency of nine hundred and twenty-five per second would maintain nine hundred and twenty-five stationary waves in a circuit one hundred and eighty-five thousand miles long and each wave would be two hundred miles in length. For such a low frequency, to which I shall resort only when it is indispensable to operate motors of the ordinary kind under the conditions above assumed, I would use a secondary of fifty miles in length. By such an adjustment or proportioning of the length of wire in the secondary coil or coils the points of highest potential are made to coincide with the elevated terminals D D, and it should be understood that whatever length be given to the wires this condition should be complied with in order to attain the best results.

As the main requirement in carrying out my invention is to produce currents of an excessively high potential, this object will be facilitated by using a primary current of very considerable frequency, since the electromotive force obtainable with a given length of conductors is proportionate to the frequency; but the frequency of the current is in a large measure arbitrary, for if the potential be sufficiently high and if the terminals of the coils be maintained at the proper altitudes the action described will take place, and a current will be transmitted through the elevated air strata, which will encounter little and possibly even less resistance than if conveyed through a copper wire of a practicable size. Accordingly the construction of the apparatus may be in many details greatly varied, but in order to enable any person skilled in the mechanical and electrical arts to utilize to advantage in the practical applications of my system the experience I have so far gained the following particulars of a model plant which has been long in use and which was constructed for the purpose of obtaining further data to be used in the carrying out of my invention on a large scale are given. The transmitting apparatus was in this case one of my electrical oscillators, which are transformers of a special type, now well known and characterized by the passage of oscillatory discharges of a condenser through the primary. The source G, forming one of the elements of the transmitter, was a condenser of a capacity of about four one-hundredths of a microfarad and was charged from a generator of alternating currents of fifty thousand volts pressure and discharged by means of a mechanically-operated break five thousand times per second through the primary C. The latter consisted of a single turn of stout stranded cable of inappreciable resistance and of an inductance of about eight thousand centimeters, the diameter of the loop being very nearly two hundred and forty-four centimeters. The total inductance of the primary circuit was approximately ten thousand centimeters, so that the primary circuit vibrated generally according to adjustment,

326036

from two hundred and thirty thousand to two hundred and fifty thousand times per second. The high tension coil A in the form of a flat spiral was composed of fifty turns of heavily-insulated cable No. 8 wound in one single layer, the turns beginning close to the primary loop and ending near its center. The outer end of the secondary or high-tension coil A was connected to the ground, as illustrated, while the free end was led to a terminal placed in the rarefied air stratum through which the energy was to be transmitted, which was contained in an insulating tube of a length of fifty feet or more, within which a barometric pressure varying from about one hundred and twenty to one hundred and fifty millimeters was maintained by means of a mechanical suction-pump. The receiving-transformer was similarly proportioned, the ratio of conversion being the reciprocal of that of the transmitter, and the primary high-tension coil A was connected, as illustrated, with the end near the low-tension coil C to the ground and with the free end to a wire or plate likewise placed in the rarefied air stratum and at the distance named from the transmitting-terminal. The primary and secondary circuits in the transmitting apparatus being carefully synchronized, an electromotive force from two to four million volts and more was obtainable at the terminals of the secondary coil A, the discharge passing freely through the attenuated air stratum maintained at the above barometric pressures, and it was easy under these conditions to transmit with fair economy considerable amounts of energy, such as are of industrial moment, to the receiving apparatus for supplying from the secondary coil C lamps L or kindred devices. The results were particularly satisfactory when the primary coil or system A, with its secondary C, was carefully adjusted, so as to vibrate in synchronism with the transmitting coil or system A C. I have, however, found no difficulty in producing with apparatus of substantially the same design and construction electromotive forces exceeding three or four times those before mentioned and have ascertained that by their means current impulses can be transmitted through much denser air strata. By the use of these I have also found it practicable to transmit notable amounts of energy through air strata not in direct contact with the transmitting and receiving terminals, but remote from them, the action of the impulses, in rendering conducting air of a density at which it normally behaves as an insulator, extending, as before remarked, to a considerable distance. The high electromotive force obtained at the terminals of coil or conductor A was, as will be seen, in the preceding instance, not so much due to a large ratio of transformation as to the joint effect of the capacities and inductances in the synchronized circuits, which effect is enhanced by a high frequency, and it will be obvious that if the latter be reduced to a moderate number the ratio of transformation should be increased, especially in cases in which it may be deemed of advantage to suppress as much as possible, and particularly in the transmitting coil A, the rise of pressure due to the above effects and to obtain the necessary electromotive force solely by a large transformation.

While electromotive forces such as are produced by the apparatus just described may be sufficient for many purposes to which my system will or may be applied, I wish to state that I contemplate using in an industrial undertaking of this kind forces greatly in excess of these, and with my present knowledge and experience in this novel field I would estimate them to range from twenty to fifty million volts and possibly more. By the use of these much greater forces large amounts of energy may be conveyed through the atmosphere to remote places or regions, and the distance of transmission may be thus extended practically without limit.

As to the elevation of the terminals I do not it is obvious that it will be determined by a number of things, as by the amount and quality of the work to be performed, by the local density and other conditions of the atmosphere, by the character of the surrounding country, and such considerations as may present themselves in individual instances. Thus if there be high mountains in the vicinity the terminals should be at a greater height, and generally they should always be, if practicable, at altitudes much greater than those of the highest objects near them in order to avoid as much as possible the loss by leakage. In some cases when small amounts of energy are required the high elevation of the terminals, and more particularly of the receiving-terminal D, may not be necessary, since, especially when the frequency of the currents is very high, a sufficient amount of energy may be collected at that terminal by electrostatic induction from the upper strata, which are rendered conducting by the active terminal of the transmitter or through which the currents from the same are conveyed.

With reference to the facts which have been pointed out above it will be seen that the altitudes required for the transmission of considerable amounts of electrical energy in accordance with this method are such as are easily accessible and at which terminals can be safely maintained, as by the aid of captive balloons supplied continuously with gas from reservoirs and held in position securely by steel wires or by any other means, devices or expedients, such as may be contrived and perfected by ingenious and skilled engineers. From my experiments and observations I conclude that with electromotive forces greatly exceeding fifteen or twenty million volts the energy of many thousands of horse-power may be transmitted over great distances, measured by many hundreds of

3166

even thousands of miles, with terminals not more than thirty to thirty-five thousand feet above the level of the sea, and even this comparatively-small elevation will be required chiefly for reasons of economy, and, if desired, it may be considerably reduced, since by such means as have been described practically any potential that is desired may be obtained, the currents through the air strata may be rendered very small, whereby the loss in the transmission may be reduced.

It will be understood that the transmitting as well as the receiving coils, transformers, or other apparatus may be in some cases movable—as, for example, when they are carried by vessels floating in the air or by ships at sea. In such a case, or generally, the connection of one of the terminals of the high-tension coil or coils to the ground may not be permanent, but may be intermittently or inductively established, and any such or similar modifications I shall consider as within the scope of my invention.

While the description here given contemplates chiefly a method and system of energy transmission to a distance through the natural media for industrial purposes, the principles which I have herein disclosed and the apparatus which I have shown will obviously have many other valuable uses—as, for instance, when it is desired to transmit intelligible messages to great distances, or to illuminate upper strata of the air, or to produce, designedly, any useful changes in the condition of the atmosphere, or to manufacture from the gases of the same products, as nitric acid, fertilizing compounds, or the like, by the action of such current impulses, for all of which and for many other valuable purposes they are eminently suitable, and I do not wish to limit myself in this respect. Obviously, also, certain features of my invention here disclosed will be useful as disconnected from the method itself—as, for example, in other systems of energy transmission, for whatever purpose they may be intended, the transmitting and receiving transformers arranged and connected as illustrated, the feature of a transmitting and receiving coil or conductor, both connected to the ground and to an elevated terminal and adjusted so as to vibrate in synchronism, the proportioning of such conductors or coils, as above specified, the feature of a receiving-transformer with its primary connected to earth and to an elevated terminal and having the operative devices in its secondary, and other features or particulars such as have been described in this specification or will readily suggest themselves to a perusal of the same. I do not claim in this application a transformer for developing or converting currents of high potential in the form herewith shown and described, and with the two coils connected together as and for the purpose set forth, having made these improvements the subject of a patent granted to me November 2, 1897, No. 593,138, nor do I claim herein the apparatus employed in carrying out the method of this application when such apparatus is specially constructed and arranged for securing the particular object sought in the present invention, as these last-named features are made the subject of an application filed as a division of this application on February 19, 1900, Serial No. 5,780.

What I now claim is—

1. The method hereinbefore described of transmitting electrical energy through the natural media, which consists in producing at a generating-station a very high electrical pressure, causing thereby a propagation or flow of electrical energy, by conduction, through the earth and the air strata, and collecting or receiving at a distant point the electrical energy so propagated or caused to flow.

2. The method hereinbefore described of transmitting electrical energy, which consists in producing at a generating station a very high electrical pressure, conducting the current caused thereby to earth and to a terminal at an elevation at which the atmosphere serves as a conductor therefor, and collecting the current by a second elevated terminal at a distance from the first.

3. The method hereinbefore described of transmitting electrical energy through the natural media, which consists in producing between the earth and a generator-terminal elevated above the same, at a generating-station, a sufficiently-high electromotive force to render elevated air strata conducting, causing thereby a propagation or flow of electrical energy, by conduction, through the air strata, and collecting or receiving at a point distant from the generating-station the electrical energy so propagated or caused to flow.

4. The method hereinbefore described of transmitting electrical energy through the natural media, which consists in producing between the earth and a generator terminal elevated above the same, at a generating-station, a sufficiently-high electromotive force to render the air strata at or near the elevated terminal conducting, causing thereby a propagation or flow of electrical energy, by conduction, through the air strata, and collecting or receiving at a point distant from the generating station the electrical energy so propagated or caused to flow.

5. The method hereinbefore described of transmitting electrical energy through the natural media, which consists in producing between the earth and a generator-terminal elevated above the same, at a generating-station, electrical impulses of a sufficiently-high electromotive force to render elevated air strata conducting, causing thereby current impulses to pass, by conduction, through the air strata, and collecting or receiving at a point distant from the generating-station, the energy of the current impulses by means of a circuit synchronized with the impulses.

6. The method hereinbefore described of

COMPLETE SPECIFICATION.

U. JAN 3

[Communicated from abroad by NIKOLA TESLA, of 46 East Houston Street, New York, United States of America, Electrician.]

Improvements relating to the Production, Regulation, and Utilization of Electric Currents of High Frequency, and to Apparatus therefor.

I, HENRY HARRIS LAKE, of the Firm of Haseltine, Lake & Co., Patent Agents, 45 Southampton Buildings, in the County of Middlesex, do hereby declare the nature of this invention and in what manner the same is to be performed, to be particularly described and ascertained in and by the following statement:—

This invention, subject of the present application, is embodied in certain improvements in methods of and apparatus for producing, regulating and utilizing electric currents of high frequency heretofore invented by Nikola Tesla, and described in British Letters Patent No. 8575, dated May 19, 1891. The method and apparatus referred to in said patent were devised for the purpose of converting, supplying and utilizing electrical energy in a form suited for the production of certain novel electrical phenomena which require currents of high potential and a higher frequency than can readily or even possibly, be developed by generators of the ordinary types or by such mechanical appliances as were theretofore known. The invention referred to was based upon the principle of charging a condenser or a circuit possessing capacity and discharging the same, generally through the primary of a transformer, the secondary of which constituted the source of working current, and under such conditions as to yield a vibratory or rapidly intermittent discharge current.

The present invention, while aiming to simplify and render more efficient the apparatus heretofore used, has for its object, primarily, to provide a means for converting such currents as are generally and most readily obtainable from the mains of ordinary systems of municipal distribution, into currents of the special character referred to, and to regulate or control and utilize such currents in a simple, economical and efficient manner. The improvements are illustrated herein in forms of apparatus adapted for use with existing circuits or systems, and which while constructed and operating on the same general principles are modified only as may be required by a direct or an alternating source of supply.

The apparatus by which the present improvements are carried out may be described in general terms as comprising a circuit from a given source of supply, in which is included or with which is connected any suitable device for making and breaking such circuit in the manner desired, a condenser arranged so as to be periodically charged by the said circuit through the instrumentality of the circuit controller, and a circuit, through which the condenser discharges, of such character that the discharge will take place in a series of rapidly recurring or intermittent impulses.

In the drawings which illustrate the invention,

Fig. 1 is a diagram of circuits and apparatus employed with a source of direct currents. Figs. 2 and 3 are modifications of the same.

Figs. 4, 5 and 6 illustrate the apparatus and circuit connections employed with a source of alternating current. Figs. 7, 8, 9, 10 are similar views illustrating the method of and apparatus for regulating the system.

[*Price 8d.*]

to raise the self induction therein, the motor may be connected in other ways, that is to say, its armature only may be connected with the circuit, or its field and armature coils may be in series and both connected with such circuit. This latter arrangement is illustrated in Figure 3, in which a terminal of the circuit A^{11} is connected to one of the binding posts of the motor [illegible] which the circuit is led through one field coil M, the brushes and commutator C^1 and the other field coil M^1, and thence to a brush F which rests upon the controller disk or cylinder C. The other terminal of the circuit connects with a second brush F^1 bearing on the controller, so that the current which passes through and operates the motor is periodically interrupted.

As an illustration of the various uses to which the apparatus may be put, the secondary L is shown in this figure as connected to two plates P, P, of any suitable character between which a current of air is maintained by a fan on the shaft of the motor G, for developing ozone or for similar purposes.

When the potential of the source of current periodically rises and falls, whether with reversals or not is immaterial, it is essential to economical operation that the intervals of interruption of the charging circuit should bear a definite time relation to the period of the current, in order that the effective potential of the impulses charging the condenser may be as high as possible. In case, therefore, an alternating or equivalent electromotive force be employed as the source of supply, a circuit controller is used which will interrupt the charging circuit at instants predetermined with reference to the variations of potential therein.

A convenient, and probably the most practicable means for accomplishing this is a synchronous motor connected with the source of supply and operating a circuit controller which first interrupts the charging current at or about the instant of highest intensity of each wave and then permits the condenser to discharge the energy stored in it, through its appropriate circuit. Such apparatus, which may be regarded as typical of the means for accomplishing this purpose, is illustrated in Figures 4, 5 and 6.

In Fig. 4, A^{11} A^{11} are the conductors taken from the mains of any alternating current generator A, and for raising the potential of such current a transformer is employed represented by the primary B and secondary B^1.

The circuit of the secondary includes the energizing coils of a synchronous motor G, and a circuit controller C fixed to the shaft of the motor.

An insulating arm O, stationary with respect to the motor shaft and adjustable with reference to the poles of the fixed magnets, carries two brushes F F^1 which bear upon the periphery of the disk C. With the parts thus arranged, the secondary circuit is completed through the coils of the motor whenever the two brushes rest upon the uninsulated segments of the disk, and interrupted through the motor at other times.

Such a motor, if properly constructed, in well understood ways, maintains very exact synchronism with the alternations of the source, and the arm O may, therefore, be adjusted to interrupt the current at any determined point of its waves. By the proper relations of insulated and conducting segments, and the motor poles, the current may be interrupted twice in each complete wave at or about the points of highest intensity.

In order that the energy stored in the motor circuit may be utilized at each break to charge the condenser H, the terminals of the latter are connected to the two brushes F F^1 or to points of the circuit adjacent thereto, so that when the circuit through the motor is interrupted the terminals of the motor circuit will be connected with the condenser. The discharge of the condenser takes place through the primary K, the circuit of which is completed simultaneously with the motor circuit and interrupted while the motor circuit is broken and the condenser being charged. The secondary impulses of high potential and great frequency are available for the operation of vacuum tubes P, single terminal lamps R, and other novel and useful purposes.

It is obvious that the supply current need not be alternating, provided it be

converted or transformed into an alternating current, before reaching the controller. For example, the present improvements are applicable to various forms of rotary transformers as is illustrated in Figs. 5 and 6.

G^1 designates a continuous current motor, here represented as having four field poles wound with coils E^{11} in shunt to the armature. The line wires A^{11} A^{11} connect with the brushes *b b* bearing on the usual commutator.

On an extension of the motor shaft is a circuit controller composed of a cylinder, the surface of which is divided into four conducting segments *c*, and four insulating segments *d*, the former being diametrically connected in pairs as shown in Fig. 6.

Through the shaft run two insulated conductors *e e* from any two commutator segments ninety degrees apart, and these connect with the two pairs of segments *c*, respectively. With such arrangement, it is evident that any two adjacent segments *c c* become the terminals of an alternating current source, so that if two brushes F F^1 be applied to the periphery of the cylinder they will take off current during such portion of the wave as the width of segment and position of the brushes may determine. By adjusting the position of the brushes relatively to the cylinder, therefore, the alternating current delivered to the segments *c c* may be interrupted at any point of its waves.

While the brushes F F^1 are on the conducting segments the current which they collect stores energy in a circuit of high self-induction formed by the wires *f f*, self-induction coils S S, the conductors A^{11} A^{11}, the brushes and commutator. When this circuit is interrupted by the brushes F F^1, passing onto the insulating segments of the controller, the high potential discharge of this circuit stores energy in the condensers H H which then discharge through the circuit of low self-induction containing the primary K. The secondary circuit contains any devices as P, R, for utilizing the current.

In some cases the energy delivered by the system may be readily and economically regulated. It is well known that every electric circuit, provided its ohmic resistance does not exceed certain definite limits, has a period of vibration of its own analogous to the period of vibration of a weighted spring. In order to alternately charge a given circuit of this character by periodic impulses impressed upon it and to discharge it most effectively, the frequency of the impressed impulses should bear a definite relation to the frequency of vibration possessed by the circuit itself. Moreover, for like reasons, the period of vibration of the discharge circuit should bear a similar relation to the impressed impulses or the period of the charging circuit. When the conditions are such that the general law of harmonic vibrations is followed, the circuits are said to be in resonance or in electro-magnetic synchronism, and this condition of the system is found to be highly advantageous.

In carrying out the invention, therefore, the electrical constants should be so adjusted that in normal operation the condition of resonance is approximately attained. To accomplish this, the number of impulses of current directed into the charging circuit per unit time is made equal to the period of the charging circuit itself, or, generally, to a harmonic thereof, and the same relations are maintained between the charging and discharge circuit. Any departure from this condition will result in a decreased output, and this fact is taken advantage of in regulating such output by varying the frequencies of the impulses or vibrations in the several circuits.

Inasmuch as the period of any given circuit depends upon the relations of its resistance, self-induction and capacity, a variation of any one or more of these may result in a variation in its period. There are, therefore, various ways in which the frequencies of vibration of the several circuits in the system may be varied, but the most practicable and efficient ways of accomplishing the desired result are the following:

(a) Varying the rate of the impressed impulses or those which are directed from the source of supply into the charging circuit, as by varying the speed of the commutator or other circuit controller.

(*b*) Varying the self-induction of the charging circuit.

(*c*) Varying the self-induction or capacity of the discharge circuit.

To regulate the output of a single circuit which has no vibration of its own, by merely varying its period would evidently require, for any extended range of regulation, a very wide range of variation of period. But in the system described, a very wide range of regulation of the output may be obtained by a very slight change of the frequency of one of the circuits when the above mentioned rules are observed.

Figs. 7, 8, 9 and 10 illustrate some of the more practicable means for effecting the regulation, as applied to a system deriving its energy from a source of direct currents.

In each of the figures A^{11} A^{11} designate the conductors of a supply circuit of continuous current, G a motor connected therewith in any of the usual ways, and operating a current controller C which serves to alternately close the supply circuit through the motor or through a self-induction coil, and to connect such motor circuit with a condenser H, the circuit of which contains a primary coil K, in proximity to which is a secondary coil L serving as the source of supply to the working circuit or that in which are connected up the devices P R for utilizing the current.

In order to secure the greatest efficiency in a system of this kind, it is essential, as before stated, that the circuits, which mainly as a matter of convenience are designated as the charging and the discharge circuits, should be approximately in resonance or electro-magnetic synchronism. Moreover, in order to obtain the greatest output from a given apparatus of this kind it is desirable to maintain as high a frequency as possible.

The electrical conditions, which are now well understood, having been adjusted to secure, as far as practical considerations will permit, these results, the regulation of the system is effected by adjusting its elements so as to depart in a greater or less degree from the above conditions with a corresponding variation of output. For example, as in Figure 7 the speed of the motor, and consequently of the controller, may be varied in any suitable manner, as by means of a rheostat R^1 in a shunt to such motor, or by shifting the position of the brushes on the main commutator of the motor or otherwise. A very slight variation in this respect by disturbing the relations between the rate of impressed impulses and the vibration of the circuit of high self-induction into which they are directed, causes a marked departure from the condition of resonance and a corresponding reduction in the amount of energy delivered by the impressed impulses to the apparatus.

A similar result may be secured by modifying any of the constants of the local circuits as above indicated. For example, in Figure 8 the choking coil B is shown as provided with an adjustable core N^1, by the movement of which into and out of the coil the self-induction, and consequently the period of the circuit containing such coil, may be varied.

As an example of the way in which the discharge circuit or that into which the condenser discharges, may be modified to produce the same result, there is shown in Figure 9 an adjustable self-induction coil R^{11} in the circuit with the condenser, by the adjustment of which coil the period of vibration of such circuit may be changed.

The same result would be secured by varying the capacity of the condenser, but if the condenser were of relatively large capacity this might be an objectionable plan, and a more practicable method is to employ a variable condenser in the secondary or working circuit, as shown in Figure 10. As the potential in this circuit is raised to a high degree, a condenser of very small capacity may be employed, and if the two circuits, primary and secondary, are very intimately and closely connected, the variation of capacity in the secondary is similar in its effects to the variation of the capacity of the condenser in the primary. As a means well adapted for this purpose two metallic plates S^1 S^1 adjustable to and from each other and constituting the two armatures of the condenser are shown.

The description of the means of regulation is confined herein to a source of supply of direct current, for to such it more particularly applies, but it will be understood that if the system be supplied by periodic impulses from any source which will effect the same results, the regulation of the system may be effected by the method herein described.

The circuit controller or the device which ensures the proper charging and discharging of the condenser may be of any construction that will perform the functions required of it. In illustration of the principle of construction and mode of operation, reference has been made only to forms of mechanism that make and break metallic contacts, but there need be no actual metallic contact, if provision be made for the passage of a spark between separated conductors. Such a device is illustrated in Figs. 11 to 15.

A designates, in Fig. 11, a generator having a commutator a^1 and brushes a^{11} bearing thereon, and also collecting rings b^{11}, b^{11}, from which an alternating current is taken by brushes b^1 in the well understood manner.

The circuit controller is mounted, in part, on an extension of the shaft c^1 of the generator, and in part on the frame of the same, or on a stationary sleeve surrounding the shaft. Its construction, in detail, is as follows:—

e^1 is a metal plate with a central hub e^{11} which is keyed or clamped to the shaft c^1. The plate is formed with segmental extensions corresponding in number to the waves of current which the generator delivers. These segments are preferably cut away, leaving only rims or frames, to one of the radial sides of which are secured bent metal plates i which serve as vanes to maintain a circulation of air when the device is in operation.

The segmental disk and vanes are contained within a close insulated box or case f mounted on the bearing of the generator, or in some other proper way, but so as to be capable of angular adjustment around the shaft. To facilitate such adjustment, a screw rod f^1, provided with a knob or handle, is shown as passing through the wall of the box. The latter may be adjusted by this rod, and when in proper position may be held therein by screwing the rod down into a depression in the sleeve or bearing as shown in Fig. 11.

Air passages g g are provided at opposite ends of the box through which air is maintained in circulation by the action of the vanes.

Through the sides of the box f, and through insulating gaskets h, when the material of the box is not a sufficiently good insulator, extend metallic terminal plugs l, l, with their ends in the plane of the conducting segmental disk e^1 and adjustable radially towards and from the edges of the segments.

Devices of this character are employed in the manner illustrated in Fig. 13.

A, in this figure, represents any source of alternating current, the potential of which is raised by a transformer of which B is the primary and B^1 the secondary.

The ends of the secondary circuit s are connected to the terminal plugs l, l, of an apparatus similar to that of Figures 11 and 12, and having segments rotating in synchronism with the alternations of the current source, preferably, as above described, by being mounted on the shaft of the generator, when the conditions so permit.

The plugs l, l, are then adjusted radially so as to approach more or less the path of the outer edges of the segmental disk, and so that during the passage of each segment in front of a plug a spark will pass between them, which completes the secondary circuit, s. The box, or the support for the plugs l, is adjusted angularly so as to bring the plugs and segments into proximity at the desired instants with reference to any phase of the current wave in the secondary circuit, and fixed in position in any proper manner.

To the plugs l, l, are also connected the terminals of a condenser or condensers, so that at the instant of the rupture of the secondary circuit s by the cessation of the sparks the energy accumulated in such circuit will rush into, and charge, the condenser.

A path of low self-induction and resistance, including a primary K of a few

turns, is provided to receive the discharge of the condenser, when the circuit s is again completed by the passage of sparks, the discharge being manifested as a succession of extremely rapid impulses.

By means of this apparatus effects of a novel and useful character are obtainable, but to still further increase the efficiency of the discharge or working current, there may be in some instances provided a means for further breaking up the individual sparks themselves. A device for this purpose is shown in Figures 14 and 15.

The box or case f in these figures is fixedly secured to the frame or bearing of the generator or motor which rotates the circuit controller in synchronism with the alternating source. Within said box is a disk e^1 fixed to the shaft e with projections d^1 extending from its edge parallel with the axis of the shaft. A similar disk e^1 on a spindle d^{11} in face of the first is mounted in a bearing in the end of the box f with a capability of rotary adjustment.

The ends of the projections d^1 are deeply serrated or several pins or narrow projections placed side by side, as shown in Fig. 14, so that as those of the opposite disks pass each other a rapid succession of sparks will pass from the projections of one disk to those of the other.

The invention is not limited to the precise devices or forms of the devices shown and described. For example, when the source of supply is a circuit of high self-induction no special choking coils or the like need be employed. So, too, the condenser as a distinctive apparatus may be dispensed with when the capacity of its circuit is sufficiently great to accomplish the desired result. The circuit controller may, as already explained, be very greatly modified and varied in construction and principle of operation without departure from the invention.

In the illustrations given of the circuit controller, the contacts and insulating spaces are arranged for charging and discharging a single condenser, but it is obvious that a single motor and circuit controller may be used to operate more than one condenser, by charging one while discharging the other or others.

Having now particularly described and ascertained the nature of the said invention and in what manner the same is to be performed, as communicated to me by my foreign correspondent, I declare that what I claim is:—

1. The apparatus herein described for converting electric currents of the kind generally obtainable from municipal systems of electric distribution, into currents of high frequency, comprising in combination a circuit of high self-induction, a circuit controller adapted to make and break such circuit, a condenser into which the said circuit discharges when interrupted, and a transformer through the primary of which the condenser discharges, as set forth.

2. The combination with a circuit of high self-induction and means for making and breaking the same, of a condenser around the point of interruption in the said circuit, and a transformer the primary of which is in the condenser circuit, as described.

3. The combination with a circuit having a high self-induction, of a circuit controller for making and breaking said circuit, a motor for driving the controller, a condenser in a circuit connected with the first around the point of interruption therein, and a transformer the primary of which is in circuit with the condenser, as set forth.

4. The combination with an electric circuit of a controller for making and breaking the same, a motor included in or connected with said circuit so as to increase its self-induction and driving the said controller, a condenser in a circuit around the controller, and a transformer through the primary of which the condenser discharges, as set forth.

5. The combination with a circuit of direct current, of a controller for making and breaking the same, a motor having its field or armature coils or both included in said circuit and driving said controller, a condenser connected

with the circuit around the point of interruption therein, and a transformer, the primary of which is in the discharge circuit of the condenser, as set forth.

6. The method herein described of converting alternating currents of relatively low frequency into currents of high frequency, which consists in charging a condenser by such currents of low frequency during determinate intervals of each wave of said current, and discharging the condenser through a circuit of such character as to produce therein a rapid succession of impulses, as set forth.

7. The combination with a source of alternating current, a condenser, a circuit controller adapted to direct the current during determinate intervals of each wave into the condenser for charging the same, and a circuit into which the condenser discharges, as set forth.

8. The combination with a source of alternating current, a synchronous motor operated thereby, a circuit controller operated by the motor and adapted to interrupt the circuit through the motor at determinate points in each wave, a condenser connected with the motor circuit and adapted on the interruption of the same to receive the energy stored therein, and a circuit into which the condenser discharges, as set forth.

9. The combination with a source of alternating current, a charging circuit in which the energy of said current is stored, a circuit controller adapted to interrupt the charging circuit at determinate points in each wave, a condenser for receiving, on the interruption of the charging circuit, the energy accumulated therein, and a circuit into which the condenser discharges when connected therewith by the circuit controller, as set forth.

10. The method of regulating the energy delivered by a system for the production of high frequency currents, and comprising a supply circuit, a condenser, a circuit through which the same discharges, and means for controlling the charging of the condenser by the supply circuit and the discharging of the same, the said method consisting in varying the relations of the frequencies of the impulses in the circuits comprising the system, as set forth.

11. The method of regulating the energy delivered by a system for the production of high frequency currents comprising a supply circuit of direct currents, a condenser adapted to be charged by the supply circuit and to discharge through another circuit, the said method consisting in varying the frequency of the impulses of current from the supply circuit, as set forth.

12. The method of producing and regulating electric currents of high frequency which consists in directing impulses from a supply circuit into a charging circuit of high self-induction, charging a condenser by the accumulated energy of such charging circuit, discharging the condenser through a circuit of low self-induction, raising the potential of the condenser discharge and varying the relations of the frequencies of the electrical impulses in the said circuits, as set forth.

13. The combination with a source of current, of a condenser adapted to be charged thereby, a circuit into which the condenser discharges in a series of rapid impulses, and a circuit controller for effecting the charging and discharge of said condenser, composed of conductors movable into and out of proximity with each other, whereby a spark may be maintained between them and the circuit closed thereby during determined intervals, as set forth.

14. The combination with a source of alternating current, of a condenser adapted to be charged thereby, a circuit into which the condenser discharges in a series of rapid impulses, and a circuit controller for effecting the charging and discharge of said condenser composed of conductors movable into and out of proximity with each other in synchronism with the alternations of the source, as set forth.

15. A circuit controller for systems of the kind described, comprising in combination a pair of angularly adjustable terminals and two or more rotating conductors mounted to pass in proximity to the said terminals, as set forth.

16. A circuit controller for systems of the kind described, comprising in

combination two sets of conductors, one capable of rotation and the other of angular adjustment whereby they may be brought into and out of proximity to each other at determinate points and one or both being subdivided so as to present a group of conducting points, as set forth.

vibrations is that their potential and amplitude, and thereby the energy transmitted is more easily increased. When the Hertzian waves are used there is a certain length of spark which must not be exceeded if the circuit is required to excite vibrations; otherwise the vibrations would be damped too much, the constraint of the system giving way gradually instead of suddenly, but this means that the effective potential is limited, which if lower oscillations are used either does not occur, or can be very easily avoided.

I have found by experiments that the oscillations produced by the discharge of Leyden jars of usual size in a circuit having moderate self-induction, are very convenient for the purpose of transmitting signals, and the experiments also shew that with an equal expenditure of energy in the transmitting circuit it is preferable to use the slower vibrations.

COMPLETE SPECIFICATION.

Improvements relating to the Transmission of Electric Telegraph Signals without Connecting Wires.

I, FERDINAND BRAUN, Professor and Doctor of Philosophy, of No. 1, Universität Strasse, Strassburg, in the Province of Alsace, German Empire, do hereby declare the nature of this invention and in what manner the same is to be performed, to be particularly described and ascertained in and by the following statement:—

My invention relates to the transmission of electric signals without connecting wires, and comprises the improvements hereinafter indicated.

The electrical vibrations may be classified into three groups.

The first group includes vibrations which are created by the relative mechanical movement of magnets and coils. These may be called electromagnetic vibrations, and are exemplified in the well known ordinary alternating currents, as used for electric light and transmission of power. Their frequency will obviously be limited by the physical conditions of machinery.

A second group of electrical vibrations has been investigated by Feddersen, and others, and these vibrations consist of oscillations which are produced by the discharge of Leyden jars with or without induction coils in circuit. The frequency of these oscillations is considerably higher than the frequency of the electromagnetic vibrations above referred to.

Third group of vibrations is that first studied by the late Dr. Hertz, and known now as Hertzian waves, and in the production of these the capacity in the circuit is not produced by means of Leyden jars and special induction coils but the capacity and induction of ordinary conductors are used.

Hitherto the attention of inventors has been principally confined to Hertzian waves for the transmission of signals between two circuits without the use of connecting wires and one object has been to increase the frequency of these waves as much as possible in order to obtain propagation in a line as straight as possible. This is exemplified by the use of the Righi transmitter. For the transmission of signals in this manner it is essential, however, that the transmitting and receiving circuits should be, so to speak, visible to each other as stated by Dr. Hertz in one of his earlier papers concerning the transmission of electric waves, and by Professor Slaby's experiments it has been shewn that various material

objects, such as sails, smoke, trees, buildings and the like, interposed between the circuits, weaken or in some cases entirely prevent communication between the same.

My invention is partially intended to obviate this inconvenience, and I do this by making use of electrical oscillations belonging to the second group above mentioned, and which have only a small frequency compared with the frequencies hitherto adopted. By this means, owing to the length of the waves, these latter are able to pass through conductors of these are of moderate thickness only. Furthermore, obstacles in the path of the waves will not project such sharply defined shadows, the waves passing round them in a manner similar to that in which sound waves pass round obstacles. Another and perhaps even more important advantage in using slower vibrations is that their potential and amplitude, and thereby the energy transmitted, is more easily increased. When the Hertzian waves are used there is a certain length of spark which must not be exceeded if the circuit is required to excite vibrations, otherwise the vibrations would be damped too much, the constraint of the system giving way gradually instead of suddenly, but this means that the effective potential is limited, which if slower oscillations are used either does not occur or can be very easily avoided.

I have found by experiments that the oscillations produced by the discharge of Leyden jars of usual size in a circuit having moderate self-induction, are very convenient for the purpose of transmitting signals, and the experiments also shew that with an equal expenditure of energy in the transmitting circuit it is preferable to use the slower vibrations.

The Leyden jar or whatever other apparatus used for the production of the electric impulses is connected with the spark gap of a Rhumkorff apparatus or a Wimshurst influence machine and provided with the well known vertical sending wire preferably of considerable length. In the receiving station the ordinary arrangement may also be used for the vertical receiving wire, the coherer, local battery and signalling device, such as Morse or the like.

In order that the invention may be clearly understood I have shown in the accompanying drawings by way of example some arrangements of circuits for transmitting signals by means of the electric oscillations above described.

In Figure 1 a Leyden jar indicated at F has its inner and outer coatings connected through the air gap σ, a coil P of small self-induction being included in the circuit. The inner coating is connected to the transmitting wire M. The jar is charged in the usual manner by means of an influence machine, inductorium or other suitable means.

In Figure 2 a secondary coil S is provided communicating with the transmitting wire M so that the oscillatory currents in the coil P are transformed into currents at an increased potential.

In place of one jar two or more can be used connected in parallel or in series. Figure 3 for example shews two jars arranged in series, or as commonly called in "cascade".

Figure 4 shows an arrangement similar to Figure 3, but in which the current is transformed, a secondary coil S being connected with the transmitting wire M.

The invention is not limited to the precise arrangements or circuits shown in the drawings, as these can be varied very considerably, and electrical oscillations of a low frequency suitable for transmitting signals according to my invention can be produced in various other ways.

Having now particularly described and ascertained the nature of my said invention and in what manner the same is to be performed, I declare that what I claim is

1. The improvement in the transmission of electrical signals without connecting wires, which consists in using electrical vibrations of comparatively low frequency such as are produced by the discharge of Leyden jars, either with or without induction coils in circuit, substantially as described.

2. For the system of wireless transmission of electrical signals the combination with a transmitting device, consisting of a spark producer, condensers and vertical sending wire, of a receiving device, consisting of a receiving wire, local battery, coherer and signalling apparatus, substantially as described.

3184-3185

intercepting wires a length of wire or a device acting by induction or capacity, or both, in such a way that it produces a difference of path of half a wave length.

Both arrangements may also be combined.

It is also possible to make the transmitter out of two crossed systems insulated from each other and to form the receiver in the same way taking care of favourable conditions of capacity. The horizontally polarised waves pass through the vertical wires or rods and *vice versa*. The advantage lies in being able to regulate the capacity and in the symmetry of arrangement and compactness within a small space which renders possible a metallic protection against unexpected interruptions.

The current collected from the frame can also be conveyed to a small primary coil and transformed in a secondary coil to greater potential, and then the coherer be excited thereby.

Moreover two metal balls, which are in so intimate contact with each other as the particles of a coherer can be inserted in the intercepting wire the quick oscillations produced thereby are conducted to the coherer. This may be of advantage in dealing with very slow waves.

The transmitter and receiver, or one of them, can also consist of plate coils or of solenoids of the usual form.

Dated the 14th day of June 1899.

W. P. THOMPSON & Co.,
322, High Holborn, London, W.C., Patent Agents for the Applicant.

COMPLETE SPECIFICATION.

Improvements in Wireless Telegraphy.

I, FERDINAND BRAUN, Professor and Doctor of Philosophy, of No. 1, Universitat Strasse, Strasburg, in the Alsace, German Empire, do hereby declare the nature of this invention and in what manner the same is to be performed, to be particularly described and ascertained in and by the following statement:—

It has already been proposed in wireless telegraphy to attach a large metal plate to the receiving wire with the object of strengthening the action thereby. But in the same degree as (under the most favourable conditions) the absolute quantity of electricity intercepted is increased, the surface to be charged is also correspondingly increased, so that the increase of potential on which the excitation of the coherer specially depends is not thereby arrived at. In conformity with this conclusion experiments have shown that this arrangement is practically useless.

The following arrangement is intended to obviate this defect.

This invention is shown by the figures (1—10), which are diagrams of the arrangements and the electrical connections, similar reference letters being provided for similar parts.

A number of parallel wires, as thin as possible, a^1, a^2, a^3 and so forth are stretched as to form a grating parallel to the direction of the electric vibrations of the transmitter; they are connected to the coherer C by means of a common connecting wire. Herein use is made of the discovery that the electro-static lines of force as well as the dielectric displacement currents when in the neighbourhood of conductors tend to come nearer to one another. In this manner practically the entire electric energy of the induction falling on the surface, is intercepted, whilst the capacity is very small. The potentials

are therefore high and the reaction favourable, as proved by experiment. The wire can of course be distributed as on a cylindrical surface.

Fig. 2 shows a symmetrical arrangement, K is a condenser, C the coherer, the action of these elements being so well known as to need no further description.

The electrodynamic reactions which occur in the single wires are hereby obviously increased only with regard to the free charges thus produced and as soon as their quantity is sufficient for the capacity of the coherer and the neighbouring surface to be charged, then practically the limit of the reaction is reached.

In order also to sum up the induced electro-motive forces, the wires must be connected in series. But doing so, as indicated in Fig. 3, then one would come to no result because, if in the front wires a^1, a^3, a^5 and so forth turned towards the transmitter, currents in the upward direction were induced then the same amount of potential would be produced in the wires a^1, a^3, a^5 and so forth, on the other side of the grating but in the opposite sense, and therefore the windings would neutralise one another. The following arrangement (Fig. 4) avoids this defect. Between the front and back wires and insulated from them a sheet of metal is inserted. This protects the back wires from direct induction so as to make them serve essentially only as conducting wires in order to sum up the electro-motive forces induced in the front side. The same object can be attained by protecting the leading off wires by surrounding metal (say in the shape of a tube).

The metal sheet may in practise be replaced by wire gauze and there is even some action if it is quite absent as the front wires themselves partially screen the back ones if suitably placed.

Finally the same object may be attained as indicated in Fig. 5. When between front and back intercepting wires a length of wire is operatively connected by means of induction or capacity or both, which wire is of such a length as to produce a difference of course of half a wave length.

Fig. 6 shows a combination of the two arrangements.

Fig. 7 a symmetrical arrangement; K is a condenser C the corresponding tube.

It is also possible to make the transmitter out of two systems of grating arranged crosswise and insulated from each other (Fig. 8) and to form the receiver in the same way having regard to favourable conditions of capacity. The horizontally polarised waves pass through the vertical wires or rods and vice versâ. The advantage lies in the possibility of regulating the capacity and the symmetry of arrangement and compactness within a small space which renders possible a metallic protection against unexpected disturbance.

The current collected from the frame can also be conveyed to a small primary coil I and transformed in a secondary coil II to greater potential, and then the coherer be excited thereby.

Moreover two metal balls S^1, S^2 can be inserted in the intercepting wire especially in dealing with the interior of a coherer, and the quick oscillations produced thereby are conducted to the coherer.

Having now particularly described and ascertained the nature of my said invention and in what manner the same is to be performed, I declare that what I claim is:—

1. An intercepting apparatus for telegraphy by electrical waves consisting of a system of parallel wires for the incoming electrical vibrations, which wires may be connected either in parallel or in series substantially as described.

2. The special arrangement of arranging the wires in two planes lying one behind the other between which planes is placed a metal plate or a lattice, substantially as described.

3. Connections between the wires devised by means of resistance, capacity or

self induction to displace the phase of the front set of wires half a wave length against the back set substantially as described

4 Two gratings of wire crossing each other at right angles and one lying behind the other, substantially as described.

Dated the 13th day of March 1900.

DEFENDANT'S EXHIBIT E-3

(Defendant's Exhibit No. 2, Baker deposition)

Boston, July 22, 1893.

Mr. John Stone Stone,
Phillips Building,
Boston, Mass.

My dear Stone:- June 20th

Your letters of July 18th and ~~20th~~ last were received in due course, and have been read with great interest. The "selective" methods of space telegraphy therein described I believe I understand sufficiently to set up and operate them.

Allow me to add that this specialization of the work which Marconi's experiments to date leave in rather primitive condition, is very important, and should be prosecuted without delay by way of further development, and protection by letters-patent.

Yours very cordially,

Luther B. Baker

June 30th 1919

My dear Bryan:-

One other limitation to the utility of the vertical wire open telegraphy system is that the radiations emanate in all directions from the transmitting wire so that within the sphere of influence of one vertical wire, all other vertical wire stations, in effect, get the signals sent from this wire and may not only pick the signals sent from it, but will be interfered with if it is the purpose of receiving signals from any other vertical wire station from which they may be attempting to receive a communication.

This difficulty may be overcome by using transmitting wires giving forth simple harmonic signal waves and receiving station signal waves or stations only capable of receiving simple harmonic signal waves.

In the existing vertical wire stations, the waves sent out and the waves received are complex harmonic waves owing to the fact that the vertical wires are not simple resonators but are capable, upon having their electrical equilibrium abruptly disturbed, of developing oscillations of a

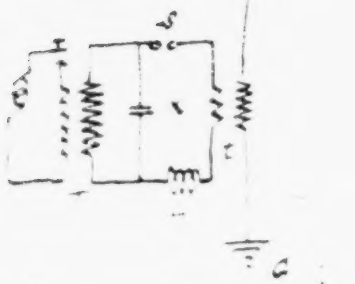
considerable number of different frequencies and also an capable of responding more or less powerfully to a correspondingly large number of different frequencies.

Instead of utilizing the vertical wire itself at the transmitting station as the oscillator, I propose to impress upon this vertical wire, oscillations from an oscillator, which oscillations shall be of a frequency corresponding to the fundamental of the wire. Similarly at the receiving station, I shall draw from the vertical wire, only that component of the complex wave which is of lower frequency.

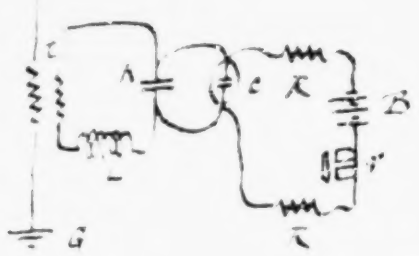
If now the fundamental of the wire at the receiving station be the same as that of the wire at the transmitting station, then the receiving station may receive signals from the transmitting station, but if it be different from that of the transmitting station, it may not receive those signals.

By such an arrangement it is obvious we shall be enabled to have a large number of vertical wire stations or numbers

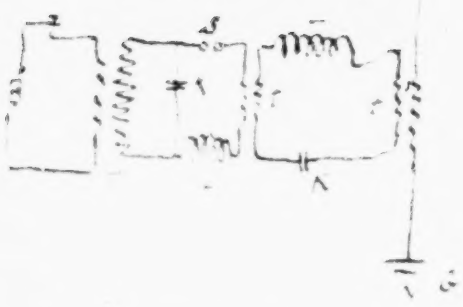
distinct from each other and receiving
stations capable of only receiving the signals
sent from the transmitting station
or stations from which it is adjusted to
receive signals and the transmitting and
receiving stations may not then interfere
with the operation of neighbouring stations.
An arrangement of the apparatus is shown
below.



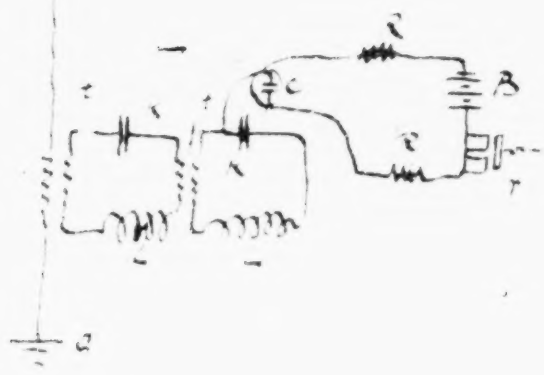
Transmitting Station



Receiving Station



Transmitting Station



Receiving Station

In these sketches, G is ground, X is condenser, C is
coil, L is inductance coil without iron,
T is step up transformer, t is transformer
with iron core, R is potentiometer coil, B is battery,
V is relay.

The tuning of these circuits one to another
and all to the same frequency will probably
be best accomplished empirically, though
the basic general proportions may be de-
termined mathematically.

Please let me know if the description I
have given in this letter is sufficient to give
you an intelligent understanding of the in-
vention and ~~to enable you~~ in your belief to
enable you to set up and operate the in-
vention without more experimental work
than that preparing to place the circuits.

Cordially yours

John Stone Stone

3653-1

Subject: Spark Telegraphy

July 15 1899

My dear Baker

As few men there who have made a special study of the subject are familiar with some of the theoretical considerations which are involved in spark telegraphy by the so called Hertzian or vortex wire system, I send you a brief description of the phenomena and of the theory.

In the usual arrangement, the essential apparatus is that shown diagrammatically in Fig 1 below in which A is the transmitting station and A' is the receiving station.

a = battery

b = key

c = inductance

d = circuit breaker

e = to primary of the spark coil I

f = secondary " " " I'

g = a spark gap

h = vertical wire

i = ground connection

k = balance

Fig. 1

When the key K is depressed the primary circuit becomes a high potential difference coil necessary which proceeds to charge the vertical wire to a high potential relative to the earth. This potential difference increases till it is sufficient to break down the air gap e whereupon the vertical wire discharges to earth through the spark gap the resistance of which is now insignificant relative to the impedance of the secondary S. The discharge of the vertical wire is oscillatory in character owing to the electro

at the capacity and inductance coefficients of self induction of the vertical wire, but owing to the fact that the electro-static capacity is distributed along the wire and is measured not uniformly distributed the different points along the wire (being at different distances from the earth) the oscillations are not simple harmonic in character but may be represented by a Fourier Series,

$A_0 + A_1 \sin pt + A_2 \sin 2pt + A_3 \sin 3pt + \&c$

$+ B_0 + B_1 \cos pt + B_2 \cos 2pt + B_3 \cos 3pt + \&c.$

The oscillatory discharge of the vertical wire sets up corresponding electro-magnetic waves surrounding it, part of which are radiated with the velocity of light.

These electro magnetic radiations, upon passing the vertical wire at the receiving station set up corresponding electro-motive forces in it. You may, if you please, regard the electro-motive forces as due to the lines of magnetic force cutting the vertical wire at the receiving station.

The electro-motive forces as set up may similarly be represented by a corresponding

Fourier's series:

$A_1' \sin p\theta + A_2' \sin 2p\theta + A_3' \sin 3p\theta + \&c$

$B_0 + B_1' \cos p\theta + B_2' \cos 2p\theta + B_3' \cos 3p\theta + \&c.$

Then since $\frac{1}{R}$ of the secondary electricity being sent to the bridges of these slight electro-motive forces and the impedance of the coils R being very great to such high frequency electro-motive forces they act in full force upon the coherer & which is surrounded by very high resistance but which when acted upon by these rapidly varying electro-motive forces is broken down as coherers and its resistance enormously diminished.

The diminution in the resistance of the coherer permits a current from the battery E of the secondary station to pass through the coherer and this current operates the secondary instrument B.

Such in brief is the general system.

In my arrangement the vibratory current overlapped in the patent wire is not due to the oscillatory discharge of the wire but is due to a simple harmonic electro-

motive force impressed upon it which electro-
motive force produces forced current
vibrations in the wire which forced vi-
brations as is well known depend for
their period and form only upon the
period and form of the impressed force
and not upon the electro-magnetic con-
stants of the circuit in which they are
enveloped as is the case with free or
natural vibrations of a system.
The current in the vertical wire in
any system may therefore be repre-
sented by a simple harmonic

$A_2 \sin pt$

and if the period of the impressed force
be the same as that of the fundamental
of the vertical wire, then it may be
represented by

$A_a \sin pt$.

The radiations will also be simple har-
monic and of the same period $\frac{1}{p}$
and will develop in the vertical wire
at the receiving station a corresponding
simple harmonic electro-motive force

of periodicity of
I mean the existence of the preceding
station a permanent circuit time to
the periodicity of. Under these circum-
stances the existence will be effected
by the sufficient from the preceding
station disturbance, but if a second
preceding station develops radiations of
periodicity of, materially different from
that the preceding apparatus will
not be affected by these radiations
even the circuit in which the existence
is created is practically effective to these
radiations as are in perfect synchronism &
the current which these radiations are
capable of exciting.
The prior transmitting circuit shown in
my letter to you of June 30th is practically
the same as that employed by Tesla for
the production of high frequency currents
except that I place an inductance coil L
in the circuit to give additional means of
tuning and to overcome by its greater in-
fluence the reaction from the induction

current developed at the transmitting station. Again the inductance of the coil L should be made large compared to the inductance of the secondary of the inductive coil t at the receiving station in order to obtain well defined resonance to a single frequency.

I believe that I was the first to discover that it was convenient to place an auxiliary inductance coil of large inductance in a secondary circuit in order to render it resonant to a definite frequency. I have also shown that it accomplishes this purpose.

In the second use of transmitting and receiving stations shown in my letter to you of June 30 ultimo, everything is the same as that shown in the first two diagrams except that an additional resonant circuit attuned to the same frequency as the others, is interposed between the vertical wire and the transmitting and receiving apparatus for the purpose of additionally sifting out the undesired harmonics..

A modification of the receiving circuit shown in my previous letter to you and a modification which I believe would be useful consist in interchanging the position of the condenser K and spark gap S in the transmitting circuit as shown in Fig 2 below.

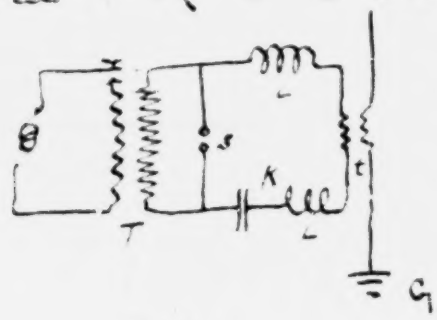


Fig 2.

A secondary effect of compensating low inductance coupling between the antenna circuit and the transformer T which has its advantages and others is due likelihood to the derived circuit through the secondary of T producing a disturbance in the periodicity of the current developed in the primary circuit B - S. K -

Cordially yours

John Stone Stone

[fol. 3207] Answer. I think so.

34. Dedirect question. Does that apply to any other part of this article?

Answer. I am afraid I do not understand your question.

35. Redirect question. Was any other part of this article as here copied written then for the first time?

Answer. The article in the book?

36. Redirect question. By "article" I mean these notes?

Answer. That is the only thing; yes, sir.

37. Redirect question. Do you now remember how you came to make this addition to the notes?

Answer. After having reread the article referred to in the lecture, I probably jotted that down to indicate the particular bearing on the subject in question.

DEFENDANT'S EXHIBIT E-3

In The United States Patent Office. Serial No. 44384. Room No. 91. Application of JOHN STONE STONE, for Apparatus for Selective Electric Signaling. Filed January 23, 1901

Affidavit of Joseph B. Baker

JOSEPH B. BAKER, of lawful age, being duly sworn, deposes and says as follows:

I am well acquainted with Mr. John Stone Stone, the applicant in the above-entitled case, having been associated with him for several years at the laboratory of the American Bell Telephone Co. at Boston, where I was engaged in electrical experimentation for that company.

I am a graduate of the Massachusetts Institute of Technology with the degree of electrical engineer, and for some [fol. 3208] years acted as electrician for the American Telephone and Telegraph Company at Boston.

I have carefully examined a copy of the specification and drawings in the above-entitled case. Prior to November, 1899, Mr. Stone, the applicant, sent to me at Newton, Mass., by mail, a full and complete written description with drawings of the invention described and claimed in this case, which I duly received and read and fully understood. Also, prior to the time above named, I wrote and mailed to Mr. Stone a letter in which I stated that I had received his description and understood it and believed myself capable of putting the same in practice.

Joseph B. Baker.

Boston, Mass., March 18, 1901.

(Defendant's Exhibit No. 5, Baker deposition)

In the United States Patent Office. Room 109. Application of John Stone Stone for patent for improvement in space telegraphy. Serial number 182544. (Case F.) Filed November 24, 1903

State of Massachusetts,
County of Suffolk, ss:

Joseph E. Baker, of lawful age, being first duly sworn, deposes and says, as follows:

I reside at Wellesley Hills, in the county of Norfolk and State of Massachusetts.

I am well acquainted with Mr. John Stone Stone, the applicant named in the above-entitled case, having been associated with him for several years at the laboratory of the American Bell Telephone Company at Boston, where I was engaged in electrical experimentation for that company.

I am a graduate of the Massachusetts Institute of Technology with the degree of electrical engineer and for some years acted as electrician for the American Telephone and Telegraph Company at Boston.

Prior to December 15, 1899, I received from Mr. Stone two letters containing a full and complete written description with drawings of a system of selective electric signaling by simple harmonic electromagnetic waves.

Also prior to December 15, 1899, I wrote and mailed to Mr. Stone a letter in which I stated that I had received his description and understood it and believed myself capable of putting the same in practice.

The photolithographic copies of the letters annexed hereto and marked "Exhibit A" and "Exhibit B" are facsimiles of the letters received by me from Mr. Stone as aforesaid. [fol. 3299] The photolithographic copy of the letter annexed hereto and marked "Exhibit C" is a facsimile of the letter sent by me to Mr. Stone in acknowledgment of his letters, as aforesaid.

I am the same Joseph B. Baker who executed an affidavit to substantially the same facts set forth above on March 18, 1901, which affidavit I am informed and believe now forms a

part of the record of patent No. 714831 in the archives of the United States Patent Office.

The letter referred to by me in said affidavit is the same letter referred to herein, a copy of which is hereunto annexed as "Exhibit A."

Boston, July 22, 1899.

MR. JOHN STONE STONE:
Phillips Building, Boston, Mass.

MY DEAR STONE: Your letters of July 18th and June 20 last were received in due course and have been read with great interest. The "selective" methods of space telegraphy

therein described I believe I understand sufficiently to set up and operate them.

Allow me to add that this specialization of the work, which Marconi's experiments to date leave in rather primitive condition, is very important, and should be prosecuted without delay by way of further development, and protection by letters.

Yours very cordially, Joseph B. Baker.

[fol. 3210] As it was necessary to send the original to Heliotype Printing Co., 211 Tremont St., on January 4th, 1904, the above copy was made by me on that date, and I hereby state it to be a true copy of the original document.

G. A. Higgins. (Seal.)

Then personally appeared before me the said G. A. Higgins and made oath that the foregoing statements by her are true.

George Lemist Clarke, *Notary Public.* (Seal.)

I hereby certify that I have compared the original letter from Joseph B. Baker to Mr. John Stone Stone, dated Boston, July 22d, 1899, with the above copy and find the above to be a true copy of the original letter before mentioned.

George Lemist Clarke, *Notary Public.*

DEFENDANT'S EXHIBIT P-3 3648

UNITED STATES PATENT OFFICE.

JOHN STONE STONE, OF BOSTON, MASSACHUSETTS, ASSIGNOR TO LOUIS E. WHICHER, ALEXANDER P. BROWNE, AND BRAINARD T. JUDKINS, TRUSTEES.

METHOD OF SELECTIVE ELECTRIC SIGNALING.

SPECIFICATION forming part of Letters Patent No. 714,756, dated December 2, 1902

Application filed February 8, 1900. Serial No. 4,505. (No model.)

To all whom it may concern:

Be it known that I, JOHN STONE STONE, a citizen of the United States, residing at Boston, in the county of Suffolk and State of Massachusetts, have invented certain new and useful Improvements in Methods of Selective Electric Signaling, of which the following is a specification.

My invention relates to the art of transmitting intelligence from one station to another by means of electromagnetic waves without the use of wires to guide the waves to their destination; and it relates more particularly to the system of such transmission in which the electromagnetic waves are developed by producing electric vibrations in an elevated conductor preferably vertically elevated.

Heretofore in signaling between two stations by means of electromagnetic waves when the stations are not connected by a conducting-wire certain disadvantageous limitations have been observed which greatly militated against the commercial value of the methods employed. When the electromagnetic waves are developed by producing natural or forced electric vibrations in a horizontal conductor, the attenuation of the waves so developed as they travel away from the conducter is found to be so great as to very seriously limit the distance to which they may be transmitted and effectively received, the chief cause of this observed phenomenon probably being that owing to the horizontal position of the conductor the plane of polarization of the waves is such as to cause the rapid absorption of the energy of the waves by the conducting-surface of the earth or water over which they travel. This difficulty has been overcome by a method of developing the waves which consists in producing natural electric vibrations in a vertically elevated conductor, in which case the plane of polarization of the wave so produced is at quadrature with that of the waves which may be developed by a horizontal wire, and in case of the vertical conductor the attenuation of the waves is observed to be very much less than in the case of the horizontal conductor, so that these waves may be transmitted to and effectively received at much greater distances. A limitation of the commercial utility of this system is, however, observed, which depends upon the fact that it has not heretofore been found possible, so far as I am aware, to direct signals sent out from a transmitting-station to the particular receiving-station with which it is desired to communicate to the exclusion of other receiving-stations equipped with equally or more sensitive receiving apparatus and located within the radius of influence of the sending-station. Electromagnetic waves have also been developed by producing natural or forced electric oscillations in loops or coils of wire at the transmitting-station and also by means of the discharge of electricity between two conducting spheres, cylinders, or cones; but in such cases the sphere of influence is so limited as to greatly restrict the commercial utility of these two methods of developing the signal-waves. In fine, the method of signaling by means of electromagnetic waves between stations not connected by a conducting-wire, in which method the electromagnetic waves are developed by electric vibrations in an elevated conductor, has great advantages over the other existing or proposed methods for accomplishing this purpose in which the electromagnetic waves are developed by other means, since in the case of the waves developed by the elevated-conductor method the waves may be transmitted to and effectively received at greater distances than by the other systems; but whereas in the systems employing the other methods of generating the waves the signals developed may, at least theoretically, be directed to the particular receiving-station with which it is desired to communicate to the exclusion of other similar receiving-stations in the neighborhood. It has heretofore been found impossible, so far as I know, to accomplish this purpose in the system employing an elevated conductor or wire as the source of the electromagnetic waves.

The object of this invention is to overcome the hereinbefore-described limitation to the system in which the waves emanate from vertical conductors, so that in such systems the transmitting-stations may selectively trans-

3649

mit their signals each to a particular receiving-station simultaneously or otherwise without mutual interference.

It is also the object of the invention to provide means whereby each of a plurality of transmitting and receiving stations in such a system may be enabled to selectively place itself in communication with any other station to the exclusion of all the remaining stations.

It is further the object of the present invention to enable the vertical or elevated conductor in such a system to be made the source of simple harmonic electromagnetic waves of any desired frequency independent of its length and other geometrical constants. Thus the frequency impressed upon the elevated conductor may or may not be the same as the natural period or fundamental of such conductor; but, as will be hereinafter explained, an elevated conductor that is aperiodic may be employed and is best adapted for use when the apparatus is to be used successively for different frequencies, and such aperiodic elevated conductor is likewise the preferred form of elevated conductor when two or more frequencies are to be simultaneously impressed upon or received by a single elevated conductor; but forced simple harmonic electrical vibrations of different periodicities may each be separately impressed upon a different elevated conductor, and the several energies of the resulting electromagnetic waves may be selectively conveyed each to a separate translating device.

Before proceeding to describe the invention certain fundamental principles relative to electrical vibrations should be stated, as these principles are involved in the art of signaling by means of what may be called "unguided electromagnetic waves."

If the electrical equilibrium of a conductor be abruptly disturbed and the conductor thereafter be left to itself, electric currents will flow in the conductor, which tend to ultimately restore the condition of electrical equilibrium. These currents may be either unidirectional or oscillatory in character, depending upon the relation between the principal electromagnetic constants of the conductor—*i. e.*, upon its electromagnetic and electrostatic capacities and its resistance. These phenomena are analogous to the mechanical phenomena which are observed when the mechanical equilibrium of a system is abruptly disturbed and the system is thereafter left to itself. In the case of a mechanical system motions result which tend to restore the mechanical equilibrium of the system. These motions may consist either of a unidirectional displacement or of to and fro vibrations of the system or parts of the system, depending upon the relations which subsist between the principal mechanical constants of the system—*i. e.*, its moments of mass and elasticity and its friction coefficients. In general the determination of the relations which must subsist in order that an oscillatory restoration of equilibrium shall take place, either in an electric or in a mechanical system, and the determination of the period of these oscillations is very difficult; but in certain simple cases both the determination of the conditions for an oscillatory restoration of equilibrium and of the period of these oscillations is quite simple.

An example of a simple mechanical system capable of an oscillatory restoration of equilibrium is to be found in the torsional pendulum, which consists of a highly elastic wire fixed at one end and supporting at its other extremity a heavy mass called the "bob." If a torsional stress be imparted to the wire of this pendulum by turning the bob about the axis of the wire and the bob be then abruptly released, the pendulum will in general execute isochronous oscillations about the axis of the suspending-wire in the process of restoration of equilibrium. An example of a simple electrical system capable of an oscillatory restoration of equilibrium is to be found in the case of a circuit consisting simply of a condenser and a coil without iron in its core, as shown in Figure 1 of the accompanying drawings, in which C is a condenser and I is a coil without iron in its core. If a charge of electricity be imparted to the condenser and if its electrodes be then connected to the coil, as shown in Fig. 1, an isochronous oscillatory current will in general be developed in the circuit in the process of restoration of its electrical equilibrium. Such a simple circuit as that shown in Fig. 1 is known as a system with a single degree of freedom, and the electric oscillations which it supports when its equilibrium is abruptly disturbed and it is then left to itself are known as the natural vibrations or oscillations of the system. These vibrations begin with a maximum of amplitude and gradually die away in accordance with what is known as an "exponential" law and are what are known as "simple harmonic vibrations." They may be represented graphically as in Fig. 2, in which A is a curve drawn to rectangular coordinates, in which the ordinates represent instantaneous values of current strength and the abscissæ represent times. When two such simple circuits are associated together inductively, as shown in Fig. 3, the system so formed is known as a system of two degrees of freedom, and in the oscillatory restorations of equilibrium of such a system the vibrations in such circuits—the currents—are in general not simple harmonic in character, but in general consist of the superposition of two simple harmonic currents, as shown in Fig. 4. In general, if a simple circuit, as shown in Fig. 1, be associated together in a system either by conductive or by inductive connections a system of at least [illegible] of freedom results, and the natural oscillations of such a system will therefore consist of the superposition of at least [illegible] currents. It is, moreover, a fact that the

3212

ent simple harmonic components of the oscillations which together constitute the oscillatory restoration of equilibrium of a complex system are in general not the same as those of the separate simple circuits when these circuits are isolated from one another; but the presence of each simple circuit modifies the natural period of each of the other circuits with which it is associated. Thus in a particular case if there be two simple circuits, the first with a natural period of .004 of a second when isolated, and the second with a period of .0025 of a second when isolated; these circuits when inductively connected, as shown in Fig. 3, may have an oscillatory restoration of equilibrium of which the simple harmonic components are .00444 of a second, and .00159 of a second, showing that the inductive association of the circuits together has increased the natural period of the high-period circuit, and decreased the natural period of the low-period circuit. It is, moreover, to be remembered that during the restoration of electric equilibrium currents of each of the periods are found in each of the circuits of the connected system.

So far we have considered the natural vibrations of electric systems—*i. e.*, the electric vibrations, by means of which the electric equilibrium of circuits is restored after it has been abruptly destroyed and the circuits are left to themselves—and we have compared the simple case of such natural electric vibrations with the corresponding natural mechanical vibrations of mechanical systems. We have seen that simple circuits may have simple harmonic natural electric oscillations and that complex circuits will in general have complex electric oscillations. We have, moreover, seen that the natural period of oscillations depended upon the electromagnetic constants of the circuit in the case of a simple circuit and that each of the periods of oscillation in the case of a complex or of interrelated circuits depended upon the electromagnetic constants of each of the interrelated circuits; but, besides the ability to execute natural vibrations or oscillations both electric and mechanical systems are capable of supporting what are termed "forced vibrations," and in the case of forced vibrations the period of the vibration is independent of the electromagnetic constants of the circuit, on the one hand, and the mechanical constants of the mechanical system, on the other hand, and depends only upon the period of the impressed force. Thus if a simple harmonic electromotive force be impressed upon a circuit free from hysteresis, whether it be a simple circuit or a complex of simple circuits, the forced vibrations or currents resulting from this impressed force will also be simple harmonic and of the same period as that of the impressed force.

In the present system of signaling by means of electromagnetic waves, in which a vertical conductor is employed as the source of electromagnetic radiations, the electric oscillations are of the kind hereinbefore described as natural vibrations, the vertical conductor being charged to a high potential relative to the surrounding earth and permitted to abruptly discharge to earth by means of an electric spark between two ball-electrodes. In such a method of developing the electromagnetic waves the oscillations are necessarily of a complex character, and therefore the resulting electromagnetic waves are of a complex character and consist of a great variety of superimposed simple harmonic vibrations of different frequencies. The vibrations consist of a simple harmonic vibration of lower period than all the others, known as the "fundamental," with a great variety of simple harmonics of higher periodicity superimposed thereon. Similarly the vertical conductor at the receiving-station is capable of receiving and responding to vibrations of a great variety of frequencies, so that the electromagnetic waves which emanate from one vertical conductor used as a transmitter are capable of exciting vibrations in any other vertical wire as a receiver, and for this reason any transmitting-station in a system of this character will operate any receiving-station within its sphere of influence, and the messages from the transmitting-station will not be selectively received by the particular receiving-station with which it is desired to communicate, but will interfere with the operation of other receiving-stations within its sphere of influence, thereby preventing them from properly responding to the signals of the transmitting-stations from which they are intended to receive their signals.

By my invention the vertical conductor of the transmitting-station is made the source of electromagnetic waves of but a single periodicity, and the translating apparatus at the receiving-station is caused to be selectively responsive to waves of but a single periodicity, so that the transmitting apparatus corresponds to a tuning-fork sending but a single simple musical tone, and the receiving apparatus corresponds to an acoustic resonator capable of absorbing the energy of that single simple musical tone only. When, however, the elevated conductor is aperiodic, it is adapted to receive or transmit all frequencies, and accordingly a single aperiodic elevated conductor may be associated with a plurality of local circuits, each attuned to a different frequency after the manner now well known in the art of multiple telegraphy by wire conductors.

When a single elevated conductor is to be made a source of a plurality of signal-waves of different frequences and when, moreover, these signal-waves are to be simultaneously developed, it is obviously necessary that the trains of waves of different frequencies developed at the elevated conductor shall be

independent of each other—i. e., it is necessary that the electric vibrations of one frequency impressed upon the elevated conductor shall not be affected by the set of signals simultaneously impressing vibrations of another frequency upon the conductor. The manner of developing the individual electric vibrations of a particular frequency described in this specification is such as to insure *per se* the required independence of the vibrations when several different frequencies are simultaneously impressed upon the elevated conductor. Several forms of such arrangements of the apparatus will, nevertheless, be herein after fully described in order to add to the completeness of the specification.

When the apparatus at a particular station is attuned to the same periodicity as that of the electromagnetic waves emanating from a particular transmitting-station, then this receiving-station will respond to and be capable of selectively receiving messages from that particular transmitting-station to the exclusion of messages simultaneously or otherwise sent from other transmitting stations in the neighborhood which generate electromagnetic waves of different periodicities. Moreover, by my invention the operator at the transmitting or receiving station may at will adjust the apparatus at his command in such a way as to place himself in communication with any one of a number of stations in the neighborhood by bringing his apparatus into resonance with the periodicity employed by the station with which communication is desired.

In order that the vertical conductor at the transmitting station shall generate harmonic electromagnetic waves of but a single frequency, I cause the electric vibrations in the conductor to be of a simple harmonic character, and this in turn I accomplish by producing what are substantially forced electric vibrations in the vertical conductor instead of producing natural vibrations in the conductor, as has heretofore been practiced. In order that the electric translating apparatus at the receiving station shall be operated only by electric waves of a single frequency and by no others, I interpose between the vertical conductor at the receiving station and the translating devices a resonant circuit or circuits attuned to the particular frequency of the electromagnetic waves which it is desired to have operate the translating devices.

Having thus described, broadly, the nature and object of the invention and the electrical principles upon which it is based, the details of the invention may best be described by reference to the drawings which accompany and form a part of this specification. The same letters, so far as may be, represent similar parts in all the figures.

Figs. 1 to 4 are diagrams already referred to. Fig. 5 is a diagram illustrating one arrangement of the transmitting-station. Fig. 6 is a diagram illustrating an arrangement of the receiving-station. Fig. 7 is a diagram illustrating another form of the transmitting-station. Fig. 8 is a diagram illustrating another form of the receiving-station. Figs. 9 and 15 are diagrams illustrating a detail of the construction at both transmitting and receiving stations. Figs. 10 and 11 are diagrams illustrative of the connection of the coherer at receiving-stations. Fig. 12 is a diagram illustrating the connection of a condenser-telephone at the receiving-station. Figs. 13 and 16 are diagrams illustrative of forms of transmitter-stations capable of developing signal-waves of two different frequencies. Figs. 14 and 17 are diagrams illustrative of forms of receiving stations capable of receiving selectively signal-waves of two different frequencies.

In the drawings, represents a vertical or virtually vertical conductor grounded in the earth connection E.

M, M', M'', and M''' are induction-coils whose primary and secondary wires are I_1, I_2, and I_3 and I_4, I_5, I_6, I_7, respectively.

L_1, L_2, and L_3 are auxiliary inductance-coils.

C, C', C'', and C''' are electrical condensers.

K and K_1 are coherers.

B is an electric battery.

a is an alternating-current generator.

k and k_1 are circuit-closing keys.

R and R' are telegraphic relays or other suitable electric translating devices.

p and *p'* are automatic circuit-interrupters.

s and *s'* are spark-gaps.

In the organization illustrated in Fig. the generator a develops an alternating electromotive force of moderate frequency, and when the key k is depressed develops a current in the primary circuit of the transformer M. The transformer M is so designed as to transform the electromotive force in the primary circuit to a very high electromotive force in the secondary. As the potential difference at the terminals of the secondary rises, the charge in the condenser C rises until the potential difference is sufficient to break down the dielectric at the spark-gap. When this occurs, the condenser C discharges through the spark s and the primary I_1 and inductance-coil L_1. This discharge is oscillatory in character and of very high frequency, as will be explained hereinafter. The high-frequency current so developed passing through the primary I_1 induces a correspondingly high frequency electromotive force and current in the secondary I_2, and forced electric vibrations result in the vertical conductor, which are practically of a single harmonic character. These simple harmonic vibrations in the conductor A develop electromagnetic waves, which are also practically simple harmonic in character, and these in turn impinging upon the vertical conductor at the receiving-station develop

corresponding simple harmonic vibrations of like frequency.

In the organization illustrated in Fig. 6 the simple harmonic electromagnetic waves of a given frequency or periodicity impinging upon the vertical conductor *r* develop therein corresponding electrical vibrations of like frequency. By means of the induction-coil M a vibratory electromotive force corresponding in frequency to the electric vibrations in the conductor *r* is induced in the secondary circuit I_1 L C C'. If the frequency of this induced electromotive force is that to which the circuit I_1 L C C' is attuned, there will be a maximum potential difference developed at the plates of the condenser C, and this potential will operate the coherer K. When the coherer K operates, the resistance of the circuit B R K is enormously diminished and the battery B develops a current which operates the translating device R. The decoherer (not shown in the drawing) is thereby set in operation and as soon as the impulse passes the coherer is restored to its sensitive condition. If, however, the frequency of the electromagnetic waves which impinge upon the vertical conductor *r* of the receiving-station depicted in Fig. 6 is not the same as that to which the circuit I_1 L C C' is attuned, the electromotive force induced in this circuit will be different from that to which the circuit will respond by virtue of resonance and there will be but a negligible potential difference developed at the plates of the condenser C. Under these circumstances the coherer K will not be operated and the signals will not actuate the translating device R.

When transmitting-stations and a corresponding number of receiving-stations are employed by adjusting the electromagnetic constants of the circuits at the various receiving-stations, these circuits may be so proportioned or tuned that the energy of the electromagnetic waves emanating from any given transmitting-station will be selectively received and absorbed at a given receiving-station.

Before proceeding to a description of the operation of the other two forms of transmitting and receiving stations shown in Figs. 7 and 8 it is to be noted that the condenser C in Fig. 5 discharges through the circuit *s* I_1 L, and its discharge is practically unaffected by its conductive connection with the circuit through I'_2. The reason for this is that the impedance offered by the circuit through I'_2 is enormously greater than that through *s* I_1 L. Also the discharge through the circuit *s* I_1 L is of very great frequency, because the frequency of the oscillations of such discharges of condensers is approximately inversely proportional to the square root of the product of the inductance of the circuit by the capacity of the condenser, and for the purpose of this invention the apparatus is so designed that the product of the capacity of the condenser by the inductance of the circuit is made numerically very small. Moreover, the oscillations in the circuit *s* I_1 L are approximately simple harmonic in character and are practically unaffected by the inductive association with the vertical wire, because of the auxiliary inductance furnished by the coil L, it being capable of demonstration that if by means of the coil L the inductance of the circuit L I_1 *s* is rendered large compared to the mutual inductance between this circuit and the vertical wire the natural oscillations which will take place in the circuit *s* I_1 L will be practically unaffected by the inductive association with the vertical wire and will therefore be practically of a simple harmonic character, as in the case of the isolated simple circuit shown in Fig. 1. The principle may for the present purpose be stated thus—that when two simple oscillators, each such as that shown in Fig. 1, are inductively associated with each other, as in Fig. 3, the system is a system of two degrees of freedom, and the natural period of oscillation of each simple circuit is modified by the presence of the other; but if the proportions of the circuits be such that the product of the inductances of the two circuits is large compared to the mutual inductance between the circuits the natural period of oscillation of each of the circuits becomes practically the same as if the circuits were isolated.

The mathematical expression for the frequency to which a circuit is resonant when it is isolated from all other circuits—*i. e.*, has but a single degree of freedom—is well known and may be stated as follows:

$$n = \frac{1}{2\pi\sqrt{C_1 L_1}}$$

from which

$$L_1 = \frac{1}{C_1 p_1},$$

where n is the frequency, C_1 is the capacity, L_1 is the inductance, and p is the periodicity, which equals $2\pi n$. In the case of a circuit of two degrees of freedom, however, in order to make the component circuits each responsive to the same frequency as when isolated—in other words, to overcome the modifying effect of the mutual inductance of each circuit upon the other—it is necessary to consider, in the case of inductive relation, the expression:

$$\frac{1}{C_1 p_2} = L_1 - \frac{M^2_{12} p \left(L_2 p - \frac{1}{C_2 p}\right)}{R^2_2 + \left(L_2 p - \frac{1}{C_2 p}\right)^2},$$

where C_1 L_1 are the capacity and inductance of the first circuit, C_2 L_2 R_2 are the capacity, inductance, and resistance, respectively, of the second circuit, and M_{12} is the mutual inductance of the circuits. From these expressions careful consideration will show that the ef-

fective inductance of the first circuit has been modified by its inductive relation with the second circuit, and it is

$$L'_1 = L_1 - \frac{M'^2_{12} p \left(L_2 p - \frac{1}{C_2 p}\right)}{R'^2_2 + \left(L_2 p - \frac{1}{C_2 p}\right)^2}$$

Similarly we have to consider the expression

$$\frac{1}{C_2 p'} = L_2 - \frac{M'^2_{12} p \left(L_2 p - \frac{1}{C_2 p}\right)}{R'^2_1 + \left(L_2 p - \frac{1}{C_2 p}\right)^2}$$

from which it will be seen that the effective inductance of the second circuit has been modified by its inductive relation with the first circuit and is

$$L'_2 = L_2 - \frac{M'^2_{12} p \left(L_1 p - \frac{1}{C_1 p}\right)}{R'^2_1 + \left(L_1 p - \frac{1}{C_1 p}\right)^2}$$

These two inductances L'_1 and L'_2 are the apparent inductances which each of these circuits would have if acting as the primary to induce simple harmonic vibrations of frequency s in the other. It is therefore necessary in order to overcome the modifying effect of the mutual inductance on either circuit to add to that circuit an auxiliary inductance-coil of inductance large compared to the term of the form:

$$\frac{M'^2 p \left(L p - \frac{1}{C p}\right)}{R'^2 + \left(L p - \frac{1}{C p}\right)^2},$$

or at least so large that when it is added to the natural inductance of the circuit the sum of their inductances is very large compared to the said term. If, further, the electric equilibrium of the circuit s I, L be abruptly disturbed and the circuit be then left without impressed force, the oscillations which are developed in it induce corresponding oscillations in the vertical wire, which oscillations are virtually forced vibrations, corresponding in frequency with the natural oscillations developed in the circuit s I, L and being practically independent, as regards their frequency, of the constants of the second circuit in which they are induced.

It is to be understood that any suitable device may be employed to develop the simple harmonic force impressed upon the vertical wire. It is sufficient to develop in the vertical wire practically simple harmonic vibrations of a fixed and high frequency.

The vertical wire may with advantage be so constructed as to be highly resonant to a particular frequency, and the harmonic vibrations impressed thereon may with advantage be of that frequency. The construction of such a vertical wire is shown and described in other applications of mine now pending.

At the receiving station shown in Fig. [illegible] the inductance-coil L is introduced in order to supply auxiliary inductance and to permit of the circuit C C' I L being attuned to a particular frequency practically independently of the constants of the vertical wire.

In both the organizations illustrated in Figs. 5 and 6 the inductance-coils L may be made adjustable and serve as a means whereby the operators may adjust the apparatus to the particular frequency which it is intended to employ.

Passing now to the organizations illustrated in Figs. 7 and 8, it is to be noted that they differ, respectively, from those illustrated in Figs. 5 and 6 in that additional resonant circuits $C' I_2 L I_2$ are interposed between the vertical conductor and the generating and translating devices, respectively.

In the transmitter arrangements illustrated in Fig. 7 the circuit $C I'_2 L I_2$ is attuned to the same period as the circuit $C' L I_1 s$ and merely tends to weed out and thereby screen the vertical wire from any harmonics which may exist in the current developed in the circuit $C' L I_1 s$. This screening action of an interposed resonant circuit is due to the well-known property of such circuits by which a resonant circuit favors the development in it of simple harmonic currents of the period to which it is attuned and strongly opposes the development in it of simple harmonic currents of other periodicities. In this organization an ordinary spark-coil, (shown at M'',) equipped in the usual way with an interrupter p and condenser C'', is employed, the current being supplied by the battery B. The operation of this organization is substantially the same as that of the organization shown in Fig. 5, hereinbefore described, except for the screening action of the circuit $C I'_2 L I_2$ and need not therefore be further described. Suffice it to say that when the source of vibratory currents is particularly rich in harmonics any suitable number of resonant circuits, each attuned to the desired frequency, may be connected inductively in series, as shown in Figs. 9 and 10, and interposed between the generating device and the vertical conductor for the purpose of screening the vertical conductor from the undesirable harmonics.

In the organization illustrated in Fig. 8 the electric resonator $C I'_2 L I_2$ interposed between the vertical conductor and the circuit containing the coherer, is attuned to the same period as the circuit L C C' I and acts to screen the coherer-circuit from the effect of all currents developed in the vertical conductor save that of the current of the particular period to which the receiving station is intended to respond. As in the case of the transmitting station, any suitable number of resonant circuits, each attuned to the particular period to which the station is desired to respond, may be

connected, as shown in Figs. 9 and 15, and interposed between the vertical conductor and the coherer-circuit. Such circuits so interposed serve to screen the receiver from the effect of all currents which may be induced in the vertical conductor that are not of the period to which the receiving-station is intended to respond.

The apparatus shown in Figs. 13, 14, 15, 16, and 17 illustrate methods of associating the apparatus hereinbefore described, and illustrated in Figs. 5, 6, 7, 8, and 9, when two or more stations are to be associated with a common elevated conductor. The operation of each individual station is the same as that already described in connection with Figs. 5, 6, 7, 8, and 9. For the sake of clearness only two stations are shown associated with the common elevated conductor V in the drawings; but it is obvious that any desired number of stations may be associated with a common elevated conductor in the same manner.

An inspection of the drawings will show that Figs. 13 and 16 illustrate two transmitting-stations of the type shown in Fig. 7 associated with a common elevated conductor, whereas Figs. 14 and 17 illustrate two receiving-stations of the type shown in Fig. 8 associated with a common elevated conductor.

When a plurality of stations are associated with a common elevated conductor, each of the stations is characterized by being tuned to a different frequency fronf that of any of the other stations so associated.

In Figs. 13, 14, 15, 16, and 17 it will be observed that the two different stations associated with a common elevated conductor have therein been differentiated by attaching a subscript to the letters of reference in the case of one of the stations and not to the letters of reference of the other station.

The operation of each of the transmitting-stations in Figs. 13 and 16 is identical with that of the transmitting-station illustrated in Fig. 7, and the operation of each of the receiving-stations shown in Figs. 14 and 17 is identical with the operation of the receiving-station illustrated in Fig. 8.

To illustrate, the step-up transformer or spark-coil M' in Figs. 13 and 16 is equipped with an interrupter *p* and condenser C'', and the current is supplied by the battery B. When the key *k* is depressed, a high potential is developed in the secondary of M'. As the potential difference at the terminals of the secondary of M' rises, the condenser C'' is charged till the resulting potential difference at *s* is sufficient to break down the spark-gap *s*. When this occurs, the condenser C'' discharges through the spark-gap *s*, the primary of M', and the inductance-coil L''. This circuit is attuned to a given high frequency, and the oscillatory current which results is therefore of that frequency. This current induces a similar current in the interposed resonant circuit L' M C' M, attuned to the same frequency, which current in turn induces a current of corresponding frequency in the conductor V M E.

Passing now to the operation of the receiving-stations shown in Figs. 14 and 17 it may be remarked that since the operation of each of these stations is identical with the operation of the receiving-station shown in Fig. 8, the energy of the waves of one particular frequency will be absorbed by one of the receiving-stations and the energy of the waves of another particular frequency will be absorbed by the other receiving-station. This selective reception of the energy of waves of a particular frequency is independent of the number of waves of different frequencies which may be simultaneously present.

It is to be here noted that the above-described methods of simultaneously transmitting and receiving space-telegraph messages by a common elevated conductor are not described as the preferred methods, since the branch circuits M M_1 in Figs. 16 and 17 are not in themselves selective and since the elevated conductors in Figs. 13 and 14 contain a number of induction-coils in series not essential to the operation of any one of the stations singly, but that any way of associating a plurality of the stations shown in Figs. 5, 6, 7, and 8 with a vertical conductor will result in a system for simultaneously transmitting and receiving space-telegraph signals, owing to the fact that these stations are in themselves innerently selective and are capable of causing the independent development of vibrations of different frequencies in the elevated conductor and of selectively absorbing the energy of waves of different frequencies.

The branch circuits M M_1 of Fig. 17 are not selective, since they contain but one element of a tuned circuit—viz., the inductance of M and M_1. Vibratory currents of whatever frequency they may be communicated by the vertical wire to these circuits will divide among them in simple inverse proportion to their electromagnetic impedances and are not selective except for a slight reaction due to the associated circuits C' M' L' and C'_1 M_1 L'_1. These reactions, so far from tending to make the branches selective to the frequencies to which their associated circuits are intended to respond, will, in fact, cause them to oppose more strongly currents of these frequencies than those to which the associated circuits are not attuned. Again, it is obvious that the inductance of the coil M in Fig. 13 is merely an additional impedance in the elevated conductor, which, to say the least, cannot assist in the development of vibrations in the elevated conductor impressed by circuit C'_1 M'_1 L'_1 M_1. The same is obviously true of the coil M_1 in the elevated conductor with reference to the operation of the circuit C' M' L'. Now passing to the transmitting station shown at Fig. 16 it is obvious that the vibrations communicated by the circuit C' M' L' to the elevated conductor V are sub-

3655

ject to a shunt due to the coil M in the other branch of the elevated conductor, and conversely the vibrations developed in the elevated conductor by the associated circuit $C_1 M_1 L_1$ are subject to a shunt due to the coil M in the other branch of the elevated conductor. Finally, the coil M in the elevated conductor in Fig. 14 can at best only present an impedance to the waves intended to be received by the circuit $C_1 M_1 L_1$, and conversely the coil M_1 in the elevated conductor can at at best only present an impedance to the vibrations intended to be received by the circuit C' M' L'.

No mention has heretofore been made of the function of the condensers shown at C' in Fig. 6 and at C'' in Fig. 8, as these condensers are not essential to the tuning of the circuits in which they are placed, but merely serve to exclude the current of the batteries B from the resonant circuits. In order that these condensers may not appreciably affect the tuning of the circuits in which they are included, and thereby lower the resonant rise of potential at the plates of the condensers C and C, (shown in Figs. 6 and 8,) they are so constructed as to have large capacities compared to the capacities of C and C' in Figs. 6 and 8, respectively.

In Figs. 6 and 8 the coherers K are shown connected in shunt-circuit to the condensers C and C, respectively; but they may be connected serially in the resonant circuit, as shown in Fig. 10, or they may be connected in shunt-circuit to the coil L and condenser C, as shown in Fig. 11.

Though a coherer has been shown and described in the specification as the means of detecting the presence of oscillations in the receiving resonant circuits, under which circumstances it operates as a telegraphic relay to control a local-battery circuit including an electric translating device, any other suitable electroreceptive device may be employed to receive the signal—as, for example, a condenser-telephone. When a condenser-telephone is employed as a receiver, the receiving resonant circuit may be that illustrated in Fig. 12, in which C is the condenser-telephone and also the capacity by which the circuit L C C' I, is attuned.

In constructing the various parts of the apparatus shown and described in this specification there is great latitude as to the special forms that may be given them; but it must be remembered that when a circuit is to be tuned and it is desired to gain a high degree of resonance both electrostatic and magnetic hysteresis must be carefully excluded from the resonant circuit. For this reason all iron should be excluded from the coils in the resonant circuits and solid dielectrics should not ordinarily be employed in the condensers. These injunctions apply to the construction of resonant circuits attuned to very high frequencies, but not with the same force to the construction of resonant circuits to be tuned to low frequencies. Another precaution to be taken in the construction of the apparatus included in the resonants circuits when very high frequency currents are employed is that conductors between which there exists a considerable potential difference during the operation of the apparatus shall be kept as far apart as practical, because of the excessive displacement currents which tend to flow in the case of high-frequency currents. For this reason it will often be found to be convenient to build the coils in the form of flat spirals instead of long spirals of several layers, as is the usual construction of coils. Flat spirals with the turns well separated in order to minimize the displacement-currents between the turns are, however, by no means the only form of coils adapted to be used in conjunction with air-condensers for the purpose of tuning circuits to high frequencies and may often be neither the best nor most convenient form of coil to employ. Therefore in defining the character of the coils to be employed for this purpose it will be of advantage to first give the general theoretical considerations which lead to a special construction of the coils and to then give a practical guide to the manner of designing the coils for a particular frequency or range of frequencies.

A coil or solenoid as usually constructed consists of many turns of cotton or silk insulated wire wound on an insulating-core, such as a glass or ebonite tube or a wooden spool, the consecutive turns being separated only by the thin insulating coating of the wire. These solenoids, moreover, are in general wound with several layers of wire, the layers also being separated from each other only by the insulating coatings of the wires. Such solenoids are well adapted to be used in conjunction with condensers having solid dielectrics for the purpose of tuning circuits to low frequencies; but neither such coils nor such condensers are available for the purpose of tuning circuits to such high frequencies as are concerned in the present invention. In the case of high frequencies the energy absorbed in the solid dielectric of the condenser, due to dielectric hysteresis, is excessive, and the displacement-currents between the adjacent turns and layers of the coil mask and neutralize the inductance of the coil. Moreover, the solid dielectric forming the core of such coils exerts a deleterious effect, which in some instances is probably partially due to its possessing a small degree of conductivity, but which must in most instances be ascribed to the high specific inductive capacity of the material and to its dielectric hysteresis.

In order to tune a circuit to a predetermined high frequency, so that it shall show a well-defined selectivity for that frequency to the exclusion of other frequencies, even to the exclusion of frequencies differing but slightly from the predetermined frequency, it is necessary not only that the condenser

3216

shall be free from dielectric hysteresis, but that the coil shall be so constructed as to behave for that frequency practically like a conductor having a fixed resistance and a fixed inductance, but devoid of capacity. Coils constructed in the usual way do not behave for high frequences as if they had a fixed resistance and inductance and no capacity, but partake more of the character of conductors having distributed resistance, inductance, and capacity. In fact, they may in some instances behave with high frequencies more like condensers than like conductors having fixed resistance and inductance and no capacity. Since a coil constructed in the usual way behaves for high frequencies as a conductor having distributed resistance, inductance, and capacity, it follows that such a coil will show for high frequencies the same quasi resonance as is observed with low frequencies in long aerial lines and cables—*i. e.*, that it will *per se* and without the intermediary of a condenser show a slight degree of selectivity for some particular frequency and for certain multiples of that frequency just as a stretched string which has distributed inertia and elasticity will respond to the particular tone called its "fundamental" and to all other tones whose periods are aliquot parts of the periods of that fundamental; but it is not with such quasi resonance that the present invention is carried into effect, and I wish it understood that I here disclaim any system employing distributed inductance and capacity as a means for tuning the resonant circuits described in this specification.

A general criterion which determines the utility of a coil for tuning a circuit to a particular high frequency is that the potential energy of the displacement-currents in the coil shall be small compared to the kinetic energy of the conduction-current flowing through the coil when the coil is traversed by a current of that frequency.

I have found that for a single-layer coil the following procedure is sufficient for practical purposes: Determine the inductance of the coil by formulæ to be found in the text-books and treatises on electricity and magnetism. This will enable the kinetic energy of the coil to be determined for any particular current and will also permit of the determination of what would be the potential gradient along the coil for the current of the frequency to be employed if the coil were devoid of distributed electrostatic capacity. Next calculate the electrostatic capacity between an end turn and each of the remaining turns of the coil. These capacities, together with the potential gradient found, will enable the potential energy to be determened, and if the ratio of the potential energy to the kinetic energy so found be neglible compared to unity the coil will practically satisfy the requirements hereinbefore mentioned. If the coil does not meet the requirements, the design should be so changed as to increase the separation between the turns, or the size of the wire should be diminished or the dimensions of the coil so otherwise altered as to decrease the distributed capacity without proportionately diminishing the inductance. The calculations may be greatly abbreviated and the liability to error greatly reduced if the results of the computations be plotted in curves.

Regarding the effect of a dielectric core in a coil to be used for tuning a circuit to a high frequency it is sufficient to state that the preferred form of support for such a coil is any skeleton frame which will hold the turns of wire in place without exposing much surface of contact to the wires and affording a minimum of opportunity for the development of displacement-currents within itself.

In this specification I have spoken of elevated conductors, vertically-elevated conductors, and vertical conductors. I wish to be understood as including in the term "elevated" conductors disposed at an angle to the earth's surface as distinguished from horizontal conductors disposed parallel to the earth's surface. By the terms "vertically-elevated" and "vertical" I refer to conductors whose disposition with regard to the earth's surface is mainly or wholly at a right angle or vertical thereto, which is the particular form of elevated conductor preferred by me for use in connection with my present improvement.

In this specification I have described the development of free or unguided electromagnetic signal-waves of a given freqhency by employing in association with an elevated conductor a circuit such as to produce therein forced simple harmonic electric vibrations of the frequency desired. I have also described a method of receiving or absorbing the energy of free or unguided simple harmonic electromagnetic waves of one frequency to the exclusion of waves of a different frequency by associating with an elevated conductor a circuit made resonant to the frequency of the waves whose energy is to be absorbed. The circuit whereby forced simple harmonic electric vibrations are produced in the elevated conductor I have shown as a circuit containing a condenser and a self-induction coil so proportioned as to make the natural vibrations of a frequency which is the frequency of the vibrations to be forced or impressed in an elevated conductor. The circuit whereby the energy of the electromagnetic waves of one frequency is absorbed to the exclusion of that of waves of other frequencies is in like manner a circuit containing a condenser and a self-induction coil so proportioned as to make the circuit resonant to a frequency which is the frequency of the waves the energy of which is to be received. Both of the circuits I have spoken of are tuned circuits, and they may be conveniently distinguished with reference to their respective functions by denominating the circuit employed in the development of the vibrations

36557

as an "oscillating" or "sonorous" circuit and by denominating the circuit employed in the reception or absorption of the vibrations as a "resonant" circuit. I prefer to make this discrimination in nomenclature for the reason that while both the circuits are resonant circuits, yet functionally only that one employed for receiving or absorbing is accurately so described. Except for this distinction in function it is well to note that all oscillating or sonorous circuits are resonant circuits, but only such resonant circuits as have their resistance less than the square foot of the ratio of four times their inductance by their capacity are oscillating or sonorous circuits.

Also throughout this specification I have described the electrical oscillations or vibrations and the free or unguided electromagnetic waves or radiations as simple harmonic. It is the object of my present invention to approach as nearly as possible to the perfect simple harmonic wave, and such object is attained to within such a degree of precision as to preclude any interference with the operation of the system by any possible departure that may exist in the wave from the absolute simple harmonic form. My reason for confining the description of the electrical oscillations or vibrations and the electromagnetic waves or vibrations to the simple harmonic type is that in the operation of the system only the simple harmonic components are effective in carrying out the object of the invention. Though it is impossible to prevent the presence of minute overtones accompanying these simple harmonic waves, such overtones not only do not contribute to the useful operation of the system, but may, in fact, become obstacles to such useful and complete operation unless their amplitude be excessively small, as is the case in the present invention. It is for this reason that I have taken every precaution to approximate as closely as may be to the true or absolute simple harmonic wave form, thereby reducing to a minimum the overtones which cause a departure from the true sine-wave.

Specifically, though it may be possible to employ the purposes of multiple and selective wireless telegraphy, electric vibrations and radiations departing considerably from the simple harmonic type by employing at the receiving end circuits selective to the fundamental of such vibrations and radiations, yet it will only be through the selective reception of that simple harmonic component of the vibrations or radiations which is their fundamental that the system will be operative. The other simple harmonic components of the vibrations or radiations add nothing to the operation of the system. Moreover, if such overtones exist in the waves emanating from a transmitting-station their presence will preclude the possibility of placing receiving-stations in the immediate neighborhood of such transmitting-station for the reception of signal-waves of frequencies corresponding to the frequencies of such overtones.

Whereas in the present specification I have used the term "elevated" conductor to describe the source of radiation of electromagnetic waves developed by forced electric vibrations impressed thereon, yet I deem it proper to point out that this expression should not be confused with the term "conductor" when used in connection with systems wherein that term is employed to denote a wire or other metallically-continuous conductor extending from a transmitting to a receiving station. It is of course obvious that in the art to which the present specification relates such a conductor is wholly absent. The vertical metallically-continuous source of radiant energy is a structure the location and function of which are confined entirely to the transmitting or it may be the receiving end of a system in which the conductor which connects the transmitting and receiving stations is the non-metallic—non-conducting, in fact—dielectric medium, which is commonly called the "ether" and which is by many assumed to be essential to the theory of the propagation of electrical and magnetic force, radiant light, and radiant heat.

Having described my invention, I claim—

1. The method of developing free or unguided simple harmonic electromagnetic waves of a definite frequency, which consists in producing forced simple harmonic electric vibrations of the same frequency in an elevated conductor.

2. The method of absorbing the energy of free or unguided, simple harmonic, electromagnetic signal-waves of one frequency, to the exclusion of the energy of like waves of a different frequency, which consists in associating with an elevated conductor a circuit resonant to the frequency of the waves, the energy of which is to be absorbed.

3. The method of distributing the energy of free or unguided electromagnetic waves which consists in independently developing forced simple harmonic electric vibrations of different frequencies in an elevated conductor and receiving the several energies of the resulting electromagnetic waves of different frequencies, each to the exclusion of the rest, in a separate electric translating device.

4. The method of distributing the energy of free or unguided electromagnetic waves which consists in independently developing a number of forced simple harmonic electric vibrations of different frequencies in an elevated conductor and receiving the several energies of the resulting electromagnetic waves, of different frequencies, each to the exclusion of the rest, in a separate circuit resonant to the same frequency as that of the waves, the energy of which is to be absorbed therein.

5. The method of distributing the energy of free or unguided electromagnetic waves which consists in developing forced simple

3220

harmonic electric vibrations of different frequencies, each in a different elevated conductor, and receiving the several energies of the resulting electromagnetic waves of different frequencies, each to the exclusion of the rest, in a separate electric translating device.

6. The method of distributing the energy of free or unguided electromagnetic waves which consists in developing a number of forced simple harmonic electric vibrations of different frequencies, each in a different elevated conductor, and receiving the several energies of the resulting electromagnetic waves of different frequencies, each to the exclusion of the rest, in a separate resonant circuit attuned to the same frequency as that of the waves, the energy of which is to be absorbed therein.

7. The method of rendering a circuit resonant to a given high frequency, which consists in balancing the reactance of an air-condenser by the reactance of a coil, the amplitude of whose potential energy is small compared to the amplitude of its kinetic energy when it is supporting a current of said given high frequency.

8. The method of constructing a coil to be used in a circuit to be made resonant to a given high frequency, which consists in so proportioning the coil that the amplitude of its potential energy shall be small compared to the amplitude of its kinetic energy when supporting a current of given high frequency.

9. The method of developing free or unguided simple harmonic electromagnetic signal-waves, which consists in discharging a condenser through a closed circuit having inductance adapted to produce under such conditions simple harmonic vibrations, and impressing the electrical vibrations so produced upon an open-circuit or elevated conductor substantially as described.

10. The method of developing free or unguided simple harmonic electromagnetic signal-waves which consists in discharging a condenser through a closed circuit having inductance adapted to produce under such conditions simple harmonic vibrations, impressing these vibrations on a resonant circuit or group thereof resonant to the frequency of these vibrations, and impressing the resulting electrical vibrations upon an open-circuit or elevated conductor.

11. The method of selectively receiving the energy of free or unguided simple harmonic electromagnetic signal-waves of different frequencies, each to the exclusion of the rest, which consists in receiving the same in an elevated conductor and translating or conveying the several energies of the resulting electrical oscillations, each to a separate circuit associated with said elevated conductor, and resonant to the frequency of the electromagnetic waves, the energy of which it is to receive.

12. The method of selectively receiving the energy of simple harmonic electromagnetic signal-waves of different frequencies, each to the exclusion of the rest, which consists in receiving the same in an elevated conductor and translating or conveying the several energies of the resulting electrical oscillations, each to a separate group of resonant circuits associated with said elevated conductor and resonant to the frequency of the electromagnetic waves the energy of which it is to receive.

13. The method of selectively receiving the energy of free or unguided simple harmonic electromagnetic signal-waves of different frequencies, each to the exclusion of the rest, which consists in receiving the same in a plurality of elevated conductors, thereby developing in each elevated conductor electrical oscillations corresponding in frequency to the electromagnetic waves received by it and in translating or conveying from each elevated conductor to an associated circuit the energy of the particular electrical oscillation to the frequency of which said associated circuit is made resonant.

14. The method of selectively receiving the energy of simple harmonic electromagnetic signal-waves of different frequencies, each to the exclusion of the rest, which consists in receiving the same in a plurality of elevated conductors, thereby developing in each elevated conductor electrical oscillations corresponding in frequency to the electromagnetic waves received by it and in translating or conveying from each elevated conductor to a group of resonant circuits associated therewith the energy of the particular electrical oscillations to the frequency of which said group of associated circuits is resonant.

15. The method of absorbing the energy of free or unguided simple harmonic electromagnetic signal-waves of one frequency to the exclusion of the energy of like waves of different frequencies which consists in associating with an elevated conductor a group of circuits, each resonant to the frequency of the waves, the energy of which is to be absorbed.

16. The method of receiving the energy of simple harmonic electromagnetic signal-waves, which consists in receiving the same in an elevated conductor and translating or conveying the energy of the resulting electrical oscillations to an electrical translating device shunted around the terminals of one of the elements of a resonant circuit associated with said elevated conductor and resonant to the frequency of the electromagnetic waves

17. The method of distributing the energy of free or unguided electromagnetic waves, which consists in independently developing a number of forced simple harmonic electric vibrations of different frequencies in an elevated conductor and receiving the several energies of the resulting electromagnetic waves of different frequencies, each to the exclusion

of the rest, in a group of circuits resonant to the same frequency as that of the waves the energy of which is to be absorbed therein.

19. The method of distributing the energy of free or unguided electromagnetic waves, which consists in developing a number of forced simple harmonic electric vibrations of different frequencies each in a different elevated conductor, and receiving the several energies of the resulting electromagnetic waves of different frequencies each to the exclusion of the rest, in a separate group of circuits resonant to the same frequency as that of the waves the energy of which is to be absorbed.

20. The method of developing free or unguided simple harmonic electromagnetic signal waves, which consists in disturbing the electrical equilibrium of a circuit comprising a condenser, and a coil having inductance adapted to produce under such conditions simple harmonic vibrations, and impressing the electrical vibrations so produced upon an open circuit or elevated conductor, substantially as described.

20. The method of developing free or unguided simple harmonic electromagnetic signal-waves, which consists in disturbing the electrical equilibrium of a circuit comprising a condenser and a coil having inductance adapted to produce under such conditions simple harmonic vibrations, impressing these vibrations on a resonant circuit or group thereof attuned to the frequency of these vibrations, and impressing the resulting electrical vibrations upon an open circuit or elevated conductor.

21. The method of receiving the energy of simple harmonic electromagnetic signal waves, which consists in receiving the same in an elevated conductor and translating or conveying the energy of the resulting electrical oscillations to an electrical translating device forming one of the elements of a resonant circuit associated with said elevated conductor and resonant to the frequency of the electromagnetic waves.

22. The method of developing free or unguided simple harmonic electromagnetic signal waves or [illegible] which consists in disturbing the electrical equilibrium of a closed oscillating circuit associated with an elevated conductor and possessing sufficient auxiliary inductance to swamp the effect of the mutual inductance between it and the elevated conductor.

23. The method of [illegible] guided simple harmonic electromagnetic signal waves or [illegible] which consists in disturbing the electrical equilibrium of a closed oscillating circuit forming part of a group of resonant [illegible] associated with an elevated conductor [illegible] possessing sufficient auxiliary inductance to swamp the effect of the mutual inductance between it and the [illegible] between it and the elevated conductor.

24. The method of developing free or unguided simple harmonic electromagnetic signal waves or radiations of different frequencies independently in a single elevated conductor, which consists in disturbing the electrical equilibrium of closed oscillating circuits associated with said elevated conductor, each being attuned to a different one of the frequencies to be developed, and each of said oscillating circuits having sufficient auxiliary inductance to swamp the effect of the mutual inductance between it and the other oscillating circuits and the said elevated conductor.

25. The method of receiving the energy of simple harmonic electromagnetic waves of a given frequency, to the exclusion of other waves of different frequencies, which consists in receiving the same in an elevated conductor and conveying the energy of the resulting electrical oscillations to a circuit associated with the elevated electrical conductor and made resonant to the frequency of the electromagnetic waves the energy of which is to be received by a condenser and an auxiliary inductance coil whose inductance is sufficient to swamp the effect of the mutual inductance between the associated circuit and the elevated conductor.

26. The method of selectively receiving the energy of simple harmonic electromagnetic signal waves of one frequency, to the exclusion of like waves of different frequencies, which consists in receiving the same upon an elevated conductor and translating or conveying the energies of the resulting electrical oscillations each to a separate circuit associated with said elevated conductor and resonant to the frequency of the electromagnetic waves the energy of which is to be received, and each having sufficient auxiliary inductance to swamp the effect of the mutual inductance between it and the other associated circuits and between it and the elevated conductor.

27. The method of developing [illegible] simple harmonic electromagnetic signal waves of a given frequency, which consists in impressing upon a [illegible] vertical conductor forced simple harmonic electrical oscillations of the same frequency.

28. The method of [illegible] simple harmonic electromagnetic [illegible] which consists in [illegible]

effect of the mutual inductance between it and the elevated conductor.

30. The method of distributing the energy of free or unguided, electromagnetic waves, which consists in independently developing a number of forced, simple harmonic, electric vibrations of different frequencies in an elevated conductor, and receiving the several energies of the resulting electromagnetic waves of different frequencies, each to the exclusion of the rest in a separate circuit resonant to the same frequency as that of the waves, the energy of which is to be absorbed, and having sufficient auxiliary inductance to swamp the effect of the mutual inductance between it and all of the circuits with which it is associated.

31. The method of distributing the energy of free or unguided, electromagnetic waves, which consists in developing a number of forced, simple harmonic, electric vibrations of different frequencies, each in a different elevated conductor, and receiving the several energies of the resulting electromagnetic waves of different frequencies, each to the exclusion of the rest, in a separate resonant circuit attuned to the same frequency as that of the waves, the energy of which is to be absorbed therein, and having sufficient auxiliary inductance to swamp the effect of the mutual inductance between it and all circuits with which it is associated.

32. The method of developing free or unguided, simple harmonic, electromagnetic signal-waves, which consists in discharging a condenser through a closed circuit having inductance adapted to produce under such conditions simple harmonic vibrations and sufficient auxiliary inductance to swamp the effect of the mutual inductance between it and an elevated conductor with which it is associated, and impressing the electrical vibrations so produced upon the said elevated conductor.

33. The method of developing free or unguided, simple harmonic, electromagnetic, signal-waves, which consists in discharging a condenser through a closed circuit having inductance adapted to produce under such conditions simple harmonic vibrations, impressing these vibrations on a resonant circuit or group thereof resonant to the frequency of these vibrations, each circuit having sufficient auxiliary inductance to swamp the effect of the mutual inductance between it and all circuits with which it is associated, and impressing the resulting electrical vibrations upon an open circuit or elevated conductor.

34. The method of selectively receiving the energy of free or unguided, simple harmonic, electromagnetic, signal-waves of different frequencies, each to the exclusion of the rest, which consists in receiving the same in an elevated conductor and translating or conveying the several energies of the resulting electrical oscillations, each to a separate circuit associated with said elevated conductor, and resonant to the frequency of the electromagnetic waves, the energy of which it is to receive, each circuit having sufficient auxiliary inductance to swamp the effect of the mutual inductance between it and all circuits with which it is associated.

35. The method of selectively receiving the energy of simple harmonic, electromagnetic, signal-waves of different frequencies, each to the exclusion of the rest, which consists in receiving the same in an elevated conductor and translating or conveying the several energies of the resulting electrical oscillations, each to a separate group of resonant circuits associated with said elevated conductor and resonant to the frequency of the electromagnetic waves, the energy of which it is to receive, each circuit having sufficient auxiliary inductance to swamp the effect of the mutual inductance between it and all circuits with which it is associated.

36. The method of selectively receiving the energy of free or unguided, simple harmonic, electromagnetic signal-waves of different frequencies, each to the exclusion of the rest, which consists in receiving the same in a plurality of elevated conductors, thereby developing in each elevated conductor electrical oscillations corresponding in frequency to the electromagnetic waves received by it and in translating or conveying from each elevated conductor to an associated circuit the energy of the particular electrical oscillations to the frequency of which said associated circuit is made resonant, each of said circuits having sufficient auxiliary inductance to swamp the effect of the mutual inductance between it and the elevated conductor and all circuits with which it is associated.

37. The method of selectively receiving the energy of simple harmonic, electromagnetic, signal-waves of different frequencies, each to the exclusion of the rest, which consists in receiving the same in a plurality of elevated conductors, thereby developing in each elevated conductor electrical oscillations corresponding in frequency to the electromagnetic waves received by it and in translating or conveying from each elevated conductor to a group of resonant circuits associated therewith the energy of the particular electrical oscillations to the frequency of which said group of associated circuits is resonant, each of said circuits having sufficient auxiliary inductance to swamp the effect of the mutual inductance between it and the elevated conductor and all circuits with which it is associated.

38. The method of absorbing the energy of free or unguided, simple harmonic, electromagnetic, signal-waves of one frequency to the exclusion of the energy of like waves of different frequencies, which consists in associating with an elevated conductor a group of circuits, each resonant to the frequency of the waves, the energy of which is to be absorbed, each circuit having sufficient auxiliary inductance to swamp the effect of the

mutual inductance between it and all circuits with which it is associated.

39. The method of receiving the energy of simple harmonic, electromagnetic signal-waves, which consists in receiving the same in an elevated conductor and translating or conveying the energy of the resulting electrical oscillations to an electrical translating device shunted around the terminals of one of the elements of a resonant circuit associated with said elevated conductor and resonant to the frequency of the electromagnetic waves, each circuit having sufficient auxiliary inductance to swamp the effect of the mutual inductance between it and all circuits with which it is associated.

40. The method of distributing the energy of free or unguided electromagnetic waves, which consists in independently developing a number of forced, simple harmonic, electric vibrations of different frequencies in an elevated conductor and receiving the several energies of the resulting electromagnetic waves of different frequencies, each to the exclusion of the rest, in a group of circuits resonant to the same frequency as that of the waves, the energy of which is to be absorbed therein, each circuit having sufficient auxiliary inductance to swamp the effect of the mutual inductance between it and all circuits with which it is associated.

41. The method of distributing the energy of free or unguided electromagnetic waves, which consists in developing a number of forced, simple harmonic, electric vibrations of different frequencies, each in a different elevated conductor, and receiving the several energies of the resulting electromagnetic waves of different frequencies, each to the exclusion of the rest, in a separate group of circuits resonant to the same frequency as that of the waves the energy of which is to be absorbed, each of said circuits having sufficient auxiliary inductance to swamp the effect of the mutual inductance between it and the elevated conductor and all circuits with which it is associated.

42. The method of developing free or unguided, simple harmonic, electromagnetic signal-waves, which consists in disturbing the electrical equilibrium of a circuit comprising a condenser, and a coil having inductance adapted to produce under such conditions simple harmonic vibrations, and impressing the electrical vibrations so produced upon an elevated conductor, each circuit having sufficient auxiliary inductance to swamp the effect of the mutual inductance between it and all circuits with which it is associated.

43. The method of developing free or unguided, simple harmonic, electromagnetic signal-waves, which consists in disturbing the electrical equilibrium of a circuit comprising a condenser and a coil having inductance adapted to produce under such conditions simple harmonic vibrations, impressing these vibrations on a resonant circuit or group thereof attuned to the frequency of these vibrations, and impressing the resulting electrical vibrations upon an elevated conductor each circuit having sufficient auxiliary inductance to swamp the effect of the mutual inductance between it and all circuits with which it is associated.

44. The method of receiving the energy of simple harmonic, electromagnetic signal-waves, which consists in receiving the same in an elevated conductor and translating or conveying the energy of the resulting electrical oscillations to an electrical translating device forming one of the elements of a resonant circuit associated with said elevated conductor and resonant to the frequency of the electromagnetic waves, each circuit having sufficient auxiliary inductance to swamp the effect of the mutual inductance between it and all circuits with which it is associated.

45. The method of absorbing the energy of free or unguided simple harmonic electromagnetic signal-waves of one frequency, to the exclusion of the energy of like waves of different frequency, which consists in receiving the same in an elevated conductor and translating or conveying the resulting electric vibrations to a circuit associated with said elevated conductor, and resonant to the frequency of the waves, the energy of which is to be received.

UNITED STATES PATENT OFFICE.

JOHN STONE STONE, OF BOSTON, MASSACHUSETTS, ASSIGNOR TO LOUIS E. WHICHER, ALEXANDER P. BROWNE, AND BRAINERD T. JUDKINS, TRUSTEES.

APPARATUS FOR SELECTIVE ELECTRIC SIGNALING.

SPECIFICATION forming part of Letters Patent No. 714,831, dated December 2, 1902.

Original application filed February 8, 1900, Serial No. 4,505. Divided and this application filed January 23, 1901. Serial No. 44,384. (No model.)

To all whom it may concern:

Be it known that I, JOHN STONE STONE, a citizen of the United States, residing at Boston, in the county of Suffolk and State of Massachusetts, have invented certain new and useful Improvements in Apparatus for Selective Electric Signaling, of which the following is a specification.

My invention relates to the art of transmitting intelligence from one station to another by means of electromagnetic waves without the use of wires to guide the waves to their destination, and it relates more particularly to the system of such transmission in which the electromagnetic waves are developed by producing electric vibrations in an elevated conductor, preferably vertically elevated.

Heretofore in signaling between two stations by means of electromagnetic waves when the stations are not connected by a conducting-wire certain disadvantageous limitations have been observed which greatly militated against the commercial value of the methods employed. When the electromagnetic waves are developed by producing natural or forced electric vibrations in a horizontal conductor, the attenuation of the waves so developed as they travel away from the conductor is found to be so great as to very seriously limit the distance to which they may be transmitted and effectively received, the chief cause of this observed phenomenon probably being that owing to the horizontal position of the conductor the plane of polarization of the waves is such as to cause the rapid absorption of the energy of the waves by the conducting surface of the earth or water over which they travel. This difficulty has been overcome by a method of developing the waves which consists in producing natural electric vibrations in a vertically-elevated conductor, in which case the plane of polarization of the wave so produced is at quadrature with that of the waves which may be developed in a horizontal wire, and in case of the vertical conductor the attenuation of the waves is observed to be very much less than in the case of the horizontal conductor, so that these waves may be transmitted to and effectively received at much greater distances. A limitation of the commercial utility of this system is, however, observed, which depends upon the fact that it has not heretofore been found possible, so far as I am aware, to direct signals sent out from a transmitter-station to the particular receiving-station with which it is desired to communicate to the exclusion of other receiving-stations equipped with equally or more sensitive receiving apparatus and located within the radius of influence of the sending-station. Electromagnetic waves have also been developed by producing natural or forced electric oscillations in loops or coils of wire at the transmitting-station and also by means of the discharge of electricity between two conducting spheres, cylinders, or cones; but in such cases the sphere of influence is so limited as to greatly restrict the commercial utility of these two methods of developing the signal-waves. In fine, the method of signaling by means of electromagnetic waves between stations not connected by a conducting-wire, in which method the electromagnetic waves are developed by electric vibrations in an elevated conductor, has great advantages over the other existing or proposed methods for accomplishing this purpose in which the electromagnetic waves are developed by other means, since in the case of the waves developed by the elevated conductor method the waves may be transmitted to and effectively received at greater distances than by the other systems, but whereas in the systems employing the other methods of generating the waves the signals developed may at least theoretically be directed to the particular receiving-station with which it is desired to communicate to the exclusion of other similar receiving-stations in the neighborhood, it has heretofore been found impossible, so far as I know, to accomplish this purpose in the system employing an elevated conductor or wire as the source of the electromagnetic waves.

The object of this invention is to overcome

36773

the hereinbefore-described limitation to the system in which the waves emanate from vertical conductors, so that in such systems the transmitting-stations may selectively transmit their signals each to a particular receiving station simultaneously or otherwise without mutual interference.

It is also the object of the invention to provide means whereby each of a plurality of transmitting and receiving stations in such a system may be enabled to selectively place itself in communication with any other station to the exclusion of all the remaining stations.

It is further the object of the present invention to enable the vertical or elevated conductor in such a system to be made the source of simple harmonic electromagnetic waves of any desired frequency independent of its length and other geometrical constants. Thus the frequency impressed upon the elevated conductor may or may not be the same as the natural period or fundamental of such conductor; but, as will be hereinafter explained, an elevated conductor that is aperiodic may be employed and is best adapted for use when the apparatus is to be used successively for different frequencies, and such aperiodic elevated conductor is likewise the preferred form of elevated conductor when two or more frequencies are to be simultaneously impressed upon or received by a single elevated conductor; but forced simple harmonic electric vibrations of different periodicities may each be separately impressed upon a different elevated conductor, and the several energies of the resulting electromagnetic waves may be selectively conveyed each to a separate translating device.

Before proceeding to describe the invention certain fundamental principles relative to electrical vibrations should be stated, as these principles are involved in the art of signaling by means of what may be called "unguided electromagnetic waves."

If the electrical equilibrium of a conductor be abruptly disturbed and the conductor thereafter be left to itself, electric currents will flow in the conductor, which tend to ultimately restore the condition of electrical equilibrium. These currents may be either unidirectional or oscillatory in character, depending upon the relation between the principal electromagnetic constants of the conductor—i. e., upon its electromagnetic and electrostatic capacities and its resistance. These phenomena are analogous to the mechanical phenomena which are observed when the mechanical equilibrium of a system is abruptly disturbed and the system is thereafter left to itself. In the case of a mechanical system motions result which tend to restore the mechanical equilibrium of the system. These motions may consist either of a unidirectional displacement or of to-and-fro vibrations of the system or parts of the system, depending upon the relations which subsist between the principal mechanical constants of the system—i. e., its moments of mass and elasticity and its friction coefficients. In general the determination of the relations which must subsist in order that an oscillatory restoration of equilibrium shall take place either in an electric or in a mechanical system and the determination of the period of these oscillations is very difficult; but in certain simple cases both the determination of the conditions for an oscillatory restoration of equilibrium and of the period of these oscillations is quite simple.

An example of a simple mechanical system capable of an oscillatory restoration of equilibrium is to be found in the torsional pendulum, which consists of a highly-elastic wire fixed at one end and supporting at its other extremity a heavy mass called the "bob." If a torsional stress be imparted to the wire of this pendulum by turning the bob about the axis of the wire and the bob be then abruptly released, the pendulum will in general execute isochronous oscillations about the axis of the suspending-wire in the process of restoration of equilibrium. An example of a simple electrical system capable of an oscillatory restoration of equilibrium is to be found in the case of a circuit consisting simply of a condenser and a coil without iron in its core, as shown in Figure 1 of the accompanying drawings, in which C is a condenser, and I is a coil without iron in its core. If a charge of electricity be imparted to the condenser and if its electrodes be then connected to the coil, as shown in Fig. 1, an isochronous oscillatory current will in general be developed in the circuit in the process of restoration of its electrical equilibrium. Such a simple circuit as that shown in Fig. 1 is known as a system with a "single degree of freedom," and the electric oscillations which it supports when its equilibrium is abruptly disturbed and it is then left to itself are known as the "natural" vibrations or oscillations of the system. These vibrations begin with a maximum of amplitude and gradually die away in accordance with what is known as an "exponential" law and are what are known as "simple harmonic vibrations." They may be represented graphically, as in Fig. 2, in which A is a curve drawn to rectangular coordinates, in which the ordinates represent instantaneous values of current strength and the abscissæ represent times. When two such simple circuits are associated together inductively, as shown in Fig. 3, the system so formed is known as a system of "two degrees of freedom," and in the oscillatory restorations of equilibrium—i. e., in the natural vibrations in such circuits—the currents are in general not simple harmonic in character, but in general consist of the superposition of the simple harmonic currents, as shown in Fig. 4. In general if n simple circuits, as shown in Fig. 5, be asso-

3238

ciated together in a system either by conductive or by inductive connections a system of at least *n* degrees of freedom results, and the natural oscillations of such a system will therefore consist of the superposition of at least *n* currents. It is, moreover, a fact that the different simple harmonic components of the oscillations which together constitute the oscillatory restoration of equilibrium of a complex system are in general not the same as those of the separate simple circuits when these circuits are isolated from one another; but the presence of each simple circuit modifies the natural period of each of the other circuits with which it is associated. Thus in a particular case if there be two simple circuits, the first with a natural period of .004 of a second when isolated and the second with a period of .0025 of a second when isolated, these circuits when inductively connected, as shown in Fig. 3, may have an oscillatory restoration of equilibrium, of which the simple harmonic components are .00444 of a second and .00159 of a second, showing that the inductive association of the circuits together has increased the natural period of the high-period circuit and decreased the natural period of the low-period circuit. It is, moreover, to be remembered that during the restoration of electric equilibrium currents of each of the periods are found in each of the circuits of the connected system.

So far we have considered the natural vibrations of electric systems—*i. e.*, the electric vibrations by means of which the electric equilibrium of circuits is restored after it has been abruptly destroyed and the circuits are left to themselves—and we have compared the simple case of such natural vibrations with the corresponding natural mechanical vibrations of mechanical systems. We have seen that simple circuits may have simple harmonic natural electric oscillations and that complex circuits will in general have complex electric oscillations. We have, moreover, seen that the natural period of oscillations depended upon the electromagnetic constants of the circuit in the case of a simple circuit and that each of the periods of oscillation in the case of a complex or of interrelated circuits depended upon the electromagnetic constants of each of the interrelated circuits; but besides the ability to execute natural vibrations or oscillations both electric and mechanical systems are capable of supporting what are termed "forced vibrations," and in the case of forced vibrations the period of the vibration is independent of the electromagnetic constants of the circuit on the one hand and the mechanical constants of the mechanical system on the other hand and depends only upon the period of the impressed force. Thus if a simple harmonic electromotive force be impressed upon a circuit free from hysteresis, whether it be a simple circuit or a complex of simple circuits, the forced vibrations or currents resulting from this impressed force will also be simple harmonic and of the same period as that of the impressed force.

In present systems of signaling by means of electromagnetic waves in which a vertical conductor is employed as the source of electromagnetic radiations the electric oscillations are of the kind hereinbefore described as "natural vibrations," the vertical conductor being charged to a high potential relative to the surrounding earth and permitted to abruptly discharge to earth by means of an electric spark between two ball-electrodes. In such a method of developing the electromagnetic waves the oscillations are necessarily of a complex character, and therefore the resulting electromagnetic waves are of a complex character and consist of a great variety of superimposed simple harmonic vibrations of different frequencies. The vibrations consist of a simple harmonic vibration of lower period than all the others, known as the "fundamental," with a great variety of simple harmonics of higher periodicity superimposed thereon. Similarly the vertical conductor at the receiving station is capable of receiving and responding to vibrations of a great variety of frequencies, so that the electromagnetic waves which emanate from one vertical conductor used as a transmitter are capable of exciting vibrations in any other vertical wire as a receiver, and for this reason any transmitting-station in a system of this character will operate any receiving station within its sphere of influence, and the messages from the transmitting station will not be selectively received by the particular receiving station with which it is desired to communicate, but will interfere with the operation of other receiving stations within its sphere of influence, thereby preventing them from properly responding to the signals of the transmitting-stations from which they are intended to receive their signals.

By my invention the vertical conductor of the transmitting-station is made the source of electromagnetic waves of but a single periodicity, and the translating apparatus at the receiving station is caused to be selectively responsive to waves of but a single periodicity, so that the transmitting apparatus corresponds to a tuning-fork, sending but a single simple musical tone, and the receiving apparatus corresponds to an acoustic resonator capable of absorbing the energy of that single simple musical tone only. When, however, the elevated conductor is aperiodic, it is adapted to receive or transmit all frequencies, and accordingly a single aperiodic elevated conductor may be associated with a plurality of local circuits each attuned to a different frequency after the manner now well known in the art of multiple telegraphy by wire conductors.

When a single elevated conductor is to be made a source of a plurality of single waves

3677.5

of different frequencies and when, moreover, these signal-waves are to be simultaneously developed, it is obviously necessary that the trains of waves of different frequencies developed in the elevated conductor shall be independent of each other—*i. e.*, it is necessary that the electric vibrations of one frequency impressed upon the elevated conductor shall not be affected by the act of simultaneously impressing vibrations of another frequency upon the conductor. The manner of developing the individual electric vibrations of a particular frequency described in this specification is such as to insure *per se* the required independence of the vibrations when several different frequencies are simultaneously impressed upon the elevated conductor. Several forms of such arrangements of the apparatus will nevertheless be hereinafter fully described in order to add to the completeness of the specification.

When the apparatus at a particular station is attuned to the same periodicity as that of the electromagnetic waves emanating from a particular transmitting-station, then this receiving-station will respond to and be capable of selectively receiving messages from that particular transmitting-station to the exclusion of messages simultaneously or otherwise sent from other transmitting-stations in the neighborhood which generate electromagnetic waves of different periodicities. Moreover, by my invention the operator at the transmitting or receiving station may at will adjust the apparatus at his command in such a way as to place himself in communication with any one of a number of stations in the neighborhood by bringing his apparatus into resonance with the periodicity employed by the station with which intercommunication is desired.

In order that the vertical conductor at the transmitting-station shall generate harmonic electromagnetic waves of but a single frequency, I cause the electric vibrations in the conductor to be of a simple harmonic character, and this in turn I accomplish by producing what are substantially forced electric vibrations in the vertical conductor in lieu of producing natural vibrations in the conductor, as has heretofore been practiced. In order that the electric translating apparatus at the receiving-station shall be operated only by electric waves of a single frequency and by no others, I interpose between the vertical conductor at the receiving-station and the translating devices a resonant circuit or circuits attuned to the particular frequency of the electromagnetic waves which it is desired to have operate the translating devices.

Having thus described, broadly, the nature and object of the invention and the electrical principles upon which it is based, the details of the invention may best be described by having reference to the drawings which accompany and form a part of this specification.

The same letters, so far as may be, represent similar parts in all the figures.

Figures 1 to 4 are diagrams already referred to. Fig. 5 is a diagram illustrating one arrangement of the transmitting-station. Fig. 6 is a diagram illustrating an arrangement of the receiving station. Fig. 7 is a diagram illustrating another form of the transmitting-station. Fig. 8 is a diagram illustrating another form of the receiving-station. Figs. 9 and 15 are diagrams illustrating a detail of the construction at both transmitting and receiving stations. Figs. 10 and 11 are diagrams illustrative of the connection of the coherer at the receiving-stations. Fig. 12 is a diagram illustrating the connection of a condenser-telephone at the receiving-station. Figs. 13 and 16 are diagrams illustrative of forms of transmitter-stations capable of developing signal-waves of two different frequencies. Figs. 14 and 17 are diagrams illustrative of forms of receiving-stations capable of receiving selectively signal-waves of two different frequencies.

In the drawings, V represents a vertical or virtually vertical conductor grounded by the earth connection E.

M, M′, M″, and M‴ are induction-coils whose primary and secondary wires are I_1, I'_1, I''_1 and I'''_1 and I_2 I'_2 I''_2, respectively.

L, L′, and L″ are auxiliary inductance-coils.

C, C′, C″, and C‴ are electrical condensers.

K and K_1 are coherers.

B is an electric battery.

a is an alternating-current generator.

k and k_1 are circuit-closing keys.

R and R_1 are telegraphic relays or other suitable electric translating devices.

p and p_1 are automatic circuit-interrupters.

s and s_1 are spark-gaps.

In the organization illustrated in Fig. 5 the generator *a* develops an alternating electromotive force of moderate frequency, which when the key *k* is depressed develops a current in the primary circuit of the transformer M. The transformer M′ is so designed as to transform the electromotive force in the primary circuit to a very high electromotive force in the secondary. As the potential difference at the terminals of the secondary I'_2 rises the charge in the condenser C increases till the potential difference is sufficient to break down the dielectric at the spark-gap *s*. When this occurs, the condenser C discharges through the spark at *s*, the primary I_1, and the inductance-coil L. This discharge is oscillatory in character and of very high frequency, as will be explained hereinafter. The high-frequency current so developed passing through the primary I_1 induces a corresponding high-frequency electromotive force and current in the secondary I_2, and forced electric vibrations result in the vertical conductor V, which are practically of a simple har-

3240

monic character. These simple harmonic vibrations in the conductor V develop electromagnetic waves, which are also practically simple harmonic in character, and these, in turn, on impinging upon the vertical conductor at the receiving-station develop therein corresponding simple harmonic vibrations of like frequency.

In the organization illustrated in Fig. 6 the simple harmonic electromagnetic waves of a given frequency or periodicity impinging upon the vertical conductor V develop therein corresponding electrical vibrations of like frequency. By means of the induction-coil M a vibratory electromotive force corresponding in frequency to the electric vibrations in the conductor V is induced in the secondary circuit I_1 L C C'. If the frequency of this induced electromotive force is that to which the circuit I_1 L C C' is attuned, there will be a maximum potential difference developed at the plates of the condenser C, and this potential will operate the coherer K. When the coherer K operates, the resistance of the circuit B R K is enormously diminished and the battery B develops a current which operates the translating device R. The decoherer (not shown in the drawings) is thereby set in operation, and as soon as the impulse passes the coherer is restored to its sensitive condition. If, however, the frequency of the electromagnetic waves which impinge upon the vertical conductor V of the receiving-station depicted in Fig. 6 is not the same as that to which the circuit I_1 L C C' is attuned, the electromotive force induced in this circuit will be different from that to which the circuit will respond by virtue of resonance, and there will be but a negligible potential difference developed at the plates of the condenser C. Under these circumstance the coherer K will not be operated and the signals will not actuate the translating device R.

When transmitting-stations and a corresponding number of receiving-stations are employed, by adjusting the electromagnetic constants of the circuits at the various stations these circuits may be so proportioned or tuned that the energy of the electromagnetic waves emanating from any given transmitting-station will be selectively received and absorbed at a given receiving-station.

Before proceeding to a description of the operation of the other two forms of transmitting and receiving stations (shown in Figs. 7 and 8) it is to be noted that the condenser C in Fig. 5 discharges through the circuit s I_1 L, and its discharge is practically unaffected by its conductive connection with the circuit through I_2. The reason for this is that the impedance offered by the circuit through I_2 is enormously greater than that through s I L. Also the discharge through the circuit s I_1 L is of very great frequency, because the frequency of the oscillations of such discharges of condensers is approximately inversely proportional to the square root of the product of the inductance of the circuit by the capacity of the condenser, and for the purpose of this invention the apparatus is so designed that the product of the capacity of the condenser by the inductance of the circuit is made numerically very small. Moreover, the oscillations in the circuit s I_1 L are approximately simple harmonic in character and are practically unaffected by the inductive association with the vertical wire because of the auxiliary inductance furnished by the coil I_1, it being capable of demonstration that if by means of the coil L the inductance of the circuit L I_1 s is rendered large compared to the mutual inductance between the circuit and the vertical wire the natural oscillations which will take place in the circuit s I_1 L will be practically unaffected by the inductive association with the vertical wire and will therefore be practically of a simple harmonic character, as in the case of the isolated simple circuit shown in Fig. 1. The principle may for the present purpose be stated thus: that when two simple oscillators, each such as that shown in Fig. 1, are inductively associated with each other, as in Fig. 3, the system is a system of two degrees of freedom, and the natural period of oscillation of each simple circuit is modified by the presence of the other; but if the proportions of the circuits be such that the product of the inductance of the two circuits is large compared to the mutual inductance between the circuits the natural period of oscillation of each of the circuits becomes practically the same as if the circuits were isolated. If, further, the electric equilibrium of the circuit s I_1 L be abruptly disturbed and the circuit be then left without impressed force, the oscillations which are developed in it induce corresponding oscillations in the vertical wire, which oscillations are virtually forced vibrations corresponding in frequency with the natural oscillations developed in the circuit s I_1 L and being practically independent as regards their frequency of the constants of the second circuit in which they are induced.

The mathematical expression for the frequency to which a circuit is resonant when it is isolated from all other circuits—*i. e.*, has but a single degree of freedom—is well known and may be stated as follows:

$$n = \frac{1}{2\pi\sqrt{C_1 L_1}}$$

from which

$$L_1 = \frac{1}{C_1 p^2}$$

where n is the frequency, C_1 is the capacity, L_1 is the inductance, and p is the periodicity which equals $2\pi n$. In the case of a circuit of two degrees of freedom, however, in order to make the component circuits each responsive

to the same frequency as when isolated—in other words, to overcome the modifying effect of the mutual inductance of each circuit upon the other—it is necessary to consider in the case of inductive relation the expression:

$$\frac{1}{C_1 p^2} = L_1 - \frac{M^2_{12} p \left(L_2 p - \frac{1}{C_2 p}\right)}{R^2_2 + \left(L_2 p - \frac{1}{C_2 p}\right)^2},$$

where C_1 L_1 are the capacity and inductance of the first circuit C_2 L_2 R_2 are the capacity, inductance, and resistance, respectively, of the second circuit and M_{12} is the mutual inductance of the circuits. From these expressions careful consideration will show that the effective inductance of the first circuit has been modified by its inductive relation with the second circuit, and it is:

$$L'_1 = L_1 - \frac{M^2_{12} p \left(L_2 p - \frac{1}{C_2 p}\right)}{R^2_2 + \left(L_2 p - \frac{1}{C_2 p}\right)^2}.$$

Similarly we have to consider the expression:

$$\frac{1}{C_2 p^2} = L_2 - \frac{M^2_{12} p \left(L_1 p - \frac{1}{C_1 p}\right)}{R^2_1 + \left(L_1 p - \frac{1}{C_1 p}\right)^2}$$

from which it will be seen that the effective inductance of the second circuit has been modified by its inductive relation with the first circuit and is

$$L'_2 = L_2 - \frac{M^2_{12} p \left(L_1 p - \frac{1}{C_1 p}\right)}{R^2_1 + \left(L_1 p - \frac{1}{C_1 p}\right)^2}.$$

These two inductances L'_1 and L'_2 are the apparent inductances which each of these circuits would have if acting as a primary to induce simple harmonic vibrations of frequency n in the other. It is therefore necessary in order to overcome the modifying effect of the mutual inductance on either circuit to add to that circuit an auxiliary inductance-coil of inductance large compared to the term of the form

$$\frac{M^2 p \left(L p - \frac{1}{C p}\right)}{R^2 + \left(L p - \frac{1}{C p}\right)^2}$$

or at least so large that when it is added to the natural inductance of the circuit the sum of their inductances is very large compared to the said term.

It is to be understood that any suitable device may be employed to develop the simple harmonic force impressed upon the vertical wire. It is sufficient to develop in the vertical wire practically simple harmonic vibrations of a fixed and high frequency.

The vertical wire may with advantage be so constructed as to be highly resonant to a particular frequency, and the harmonic vibrations impressed thereon may with advantage be of that frequency. The construction of such a vertical wire is shown and described in other applications of mine now pending.

At the receiving-station shown in Fig. 6 the inductance-coil L is introduced in order to supply auxiliary inductance and to permit of the circuit C C' I_1 L being attuned to a particular frequency practically independently of the constants of the vertical wire.

In both the organizations illustrated in Figs. 5 and 6 the inductance-coils L may be made adjustable and serve as a means whereby the operators may adjust the apparatus to the particular frequency which it is intended to employ.

Passing now to the organizations illustrated in Figs. 7 and 8, it is to be noted that they differ, respectively, from those illustrated in Figs. 5 and 6 in that additional resonant circuits C I'_1 L_1 are interposed between the vertical conductor and the generating and translating devices, respectively.

In the transmitter arrangements illustrated in Fig. 7 the circuit C I'_1 L_1 is attuned to the same period as the circuit C' L' I'_1, and merely tends to weed out and thereby screen the vertical wire from any harmonics which may exist in the current developed in the circuit C' L' I'_1. This screening action of an interposed resonance-circuit is due to the well-known property of such circuits by which a resonant circuit favors the development in it of simple harmonic currents of the period to which it is attuned and strongly opposes the development in it of simple harmonic currents of other periodicities. In this organization an ordinary spark-coil, (shown at M",) equipped in the usual way with an interrupter and condenser C", is employed, the current being supplied by the battery B. The operation of this organization is substantially the same as that of the organization shown in Fig. 5, hereinbefore described, except for the screening action of the circuit C I'_1 L_1 and need not, therefore, be further described. Suffice it to say that when the source of vibratory currents is particularly rich in harmonics any suitable number of resonant circuits each attuned to the desired frequency may be connected inductively in series, as shown in Figs. 9 and 15, and interposed between the generating device and the vertical conductor for the purpose of screening the vertical conductor from the undesirable harmonics.

In the organization illustrated in Fig. 8 the electric resonator C I_2 L_2, interposed between the vertical conductor and the circuit containing the coherer, is attuned to the same period as the circuit L C C' I_1 and acts to screen the coherer-circuit from the effect of all currents developed in the vertical conductor save that of the current of the particular period to which the receiving-station is

intended to respond. As in the case of the transmitting-station, any suitable number of resonant circuits, each attuned to the particular period to which the station is desired to respond, may be connected, as shown in Figs. 9 and 15, and interposed between the vertical conductor and the coherer circuit. Such circuits so interposed serve to screen the receiver from the effects of all currents which may be induced in the vertical conductor that are not of the period to which the receiving-station is intended to respond.

No mention has heretofore been made of the function of the condensers shown at C in Fig. 6 and at C in Fig. 8, as those condensers are not essential to the tuning of the circuits in which they are placed, but merely serve to exclude the current of the batteries B from the resonant circuits. In order that these condensers may not appreciably affect the tuning of the circuits in which they are included, and thereby lower the resonant rise of potential at the plates of the condensers C and C, (shown in Figs. 6 and 8,) they are so constructed as to have large capacities compared to the capacities of C and C in Figs. 6 and 8, respectively.

In Figs. 6 and 8 the coherers K are shown connected in shunt-circuit to the condensers C and C, respectively; but they may be connected serially in the resonant circuit, as shown in Fig. 10, or they may be connected in shunt-circuit to the coil L and condenser C, as shown in Fig. 11.

Though a coherer has been shown and described in the specification as the means of detecting the presence of oscillations in the receiving resonant circuits, under which circumstances it operates as a telegraphic relay to control a local battery circuit including an electric translating device, any other suitable electroreceptive device may be employed to receive the signal—as, for example, a condenser telephone. When a condenser telephone is employed as a receiver, the receiving resonant circuit may be that illustrated in Fig. 12, in which C is the condenser-telephone and also the capacity by which the circuit L C C' I, is attuned.

The apparatus shown in Figs. 13, 14, 15, 16, and 17 illustrates methods of associating the apparatus hereinbefore described, and illustrated in Figs. 5, 6, 7, 8, and 9, when two or more stations are to be associated with a common elevated conductor. The operation of each individual station is the same as that already described in connection with Figs. 5, 6, 7, 8, and 9. For the sake of clearness only two stations are shown associated with the common elevated conductor V in the drawings, but it is obvious that any desired number of stations may be associated with a common elevated conductor in the same manner.

An inspection of the drawings will show that Figs. 13 and 16 illustrate two transmitting-stations of the type shown in Fig. 7 associated with a common elevated conductor, whereas Figs. 14 and 17 illustrate two receiving-stations of the type shown in Fig. 8 associated with a common elevated conductor.

When a plurality of stations are associated with a common elevated conductor, each of the stations is characterized by being tuned to a different frequency from that of any of the other stations so associated. In Figs. 13, 14, 15, 16, and 17 it will be observed that the two different stations associated with a common elevated conductor have therein been differentiated by attaching a subscript to the letters of reference in the case of one of the stations and not to the letters of reference of the other station.

The operation of each of the transmitting-stations in Figs. 13 and 16 is identical with that of the transmitting-station illustrated in Fig. 7, and the operation of each of the receiving-stations shown in Figs. 14 and 17 is identical with the operation of the receiving-station illustrated in Fig. 8.

To illustrate, the step-up transformer or spark-coil M in Figs. 13 and 16 is equipped with an interrupter p and condenser C'', and the current is supplied by the battery B. When the key k is depressed, a high potential is developed in the secondary of M''. As the potential difference at the terminals of the secondary of M rises the condenser C'' is charged till the resulting potential difference at s is sufficient to break down the spark-gap s. When this occurs, the condenser C'' discharges through the spark at s, the primary of M, and the inductance-coil L. This circuit is attuned to a given high frequency, and the oscillatory current which results is therefore of that frequency. This current induces a similar current in the interposed resonant circuit L' M' C M attuned to the same frequency, which current in turn induces a current of corresponding frequency in the conductor V M E.

Passing now to the operation of the receiving stations shown in Figs. 14 and 17, it may be remarked that since the operation of each of these stations is identical with the operation of the receiving-station shown in Fig. 8 the energy of the waves of one particular frequency will be absorbed by one of the receiving stations and the energy of the waves of another particular frequency will be absorbed by the other receiving-station. This selective reception of the energy of waves of a particular frequency is independent of the number of waves of different frequencies which may be simultaneously present.

It is to be here noted that the above-described methods of simultaneously transmitting and receiving space-telegraph messages by a common elevated conductor are not described as the preferred methods, but that any way of associating a plurality of the stations shown in Figs. 5, 6, 7, and 8 with a vertical conductor will result in a system for simultaneously transmitting and receiving space-telegraph signals, owing to the fact that these sta-

tions are in themselves inherently selective and are capable of causing the independent development of vibrations of different frequencies in the elevated conductor and of selectively absorbing the energy of different frequencies, since the branch circuits M M in Figs. 16 and 17 are not in themselves selective and since the elevated conductors in Figs. 13 and 14 contain a number of induction-coils in series not essential to the operation of any one of the stations singly.

The branch circuits M M of Fig. 17 are not selective, since they contain but one element of a tuned circuit—viz., the inductance of M and M. Vibratory currents, of whatever frequency they may be, communicated by the vertical wire to these circuits will divide among them in single inverse proportion to their electromagnetic impedances and are not selective except for a slight reaction due to the associated circuits C M L and C M L. These reactions, so far from tending to make the branches selective to the frequencies to which their associated circuits are intended to respond, will, in fact, cause them to oppose more strongly currents of these frequencies than those to which the associated circuits are not attuned. Again, it is obvious that the inductance of the coil M in Fig. 13 is merely an additional impedance in the elevated conductor, which, to say the least, cannot assist in the development of vibrations in the elevated conductor impressed by circuit C_1 M_1 L_1 M_2. The same is obviously true of the coil M_1 in the elevated conductor with reference to the operation of the circuit C M L. Now passing to the transmitting station shown at Fig. 16, it is obvious that the vibrations communicated by the circuit C M L to the elevated conductor V are subject to a shunt due to the coil M_1 in the other branch of the elevated conductor, and, conversely, the vibrations developed in the elevated conductor by the associated circuit C_1 M_1 L_1 are subject to a shunt due to the coil M in the other branch of the elevated conductor. Finally, the coil M in the elevated conductor in Fig. 14 can at best only present an impedance to the waves intended to be received by the circuit C_1 M_1 L_1, and, conversely, the coil M_1 in the elevated conductor can at best only present an impedance to the vibrations intended to be received by the circuit C M L.

In constructing the various parts of the apparatus shown and described in this specification there is great latitude as to the special forms that may be given them; but it must be remembered that when a circuit is to be tuned and it is desired to gain a high degree of resonance both electrostatic and magnetic hysteresis must be carefully excluded from the resonant circuit. For this reason all iron should be excluded from the coils in the resonant circuits, and solid dielectrics should not ordinarily be employed in the condensers. These injunctions apply to the construction of resonant circuits attuned to very high frequencies, but not with the same force to the construction of resonant circuits to be tuned to low frequencies. Another precaution to be taken in the construction of the apparatus included in the resonant circuits when very high-frequency currents are employed is that conductors between which there exists a considerable potential difference during the operation of the apparatus shall be kept as far apart as practical, because of the excessive displacement-currents which tend to flow in the case of high-frequency currents. For this reason it will often be found to be convenient to build the coils the form of flat spirals instead of long spirals of several layers, as is the usual construction of coils. Flat spirals with the turns well separated in order to minimize the displacement currents between the turns are, however, by no means the only forms of coils adapted to be used in conjunction with air-condensers for the purpose of tuning circuits to high frequencies and may often be neither the best nor most convenient form of coil to employ. Therefore in defining the character of the coils to be employed for this purpose it will be of advantage to first give the general theoretical considerations which lead to a special construction of the coils and to then give a practical guide to the manner of designing the coils for a particular frequency or range of frequencies.

A coil or solenoid as usually constructed consists of many turns of cotton or silk insulated wire wound on an insulating-core, such as a glass or ebonite tube or a wooden spool, the consecutive turns being separated only by the thin insulating coating of the wire. These solenoids, moreover, are in general wound with several layers of wire, the layers also being separated from each other only by the insulating coatings of the wires. Such solenoids are well adapted to be used in conjunction with condensers having solid dielectrics for the purpose of tuning circuits to low frequencies; but neither such coils nor such condensers are available for the purpose of tuning circuits to such high frequencies as are concerned in the present invention. In the case of high frequencies the energy absorbed in the solid dielectric of the condenser due to dielectric hysteresis is excessive and the displacement-currents between the adjacent turns and layers of the coil mask and neutralize the inductance of the coil. Moreover, the solid dielectric forming the core of such coils exerts a deleterious effect, which in some instances is probably partially due to its possessing a small degree of conductivity, but which must in most instances be ascribed to the high specific inductive capacity of the material and to its dielectric hysteresis.

In order to tune a circuit to a predetermined high frequency, so that it shall show a well-defined selectivity for that frequency to the exclusion of other frequencies, even to the exclusion of frequencies differing but slightly from the predetermined frequency, it is nec-

essary not only that the condenser shall be free from dielectric hysteresis, but that the coil shall be so constructed as to behave for that frequency practically like a conductor having a fixed resistance and a fixed inductance, but devoid of capacity. Coils constructed in the usual way do not behave for high frequencies as if they had a fixed resistance and inductance and no capacity, but partake more of the character of conductors having distributed resistance, inductance, and capacity. In fact, they may in some instances behave with high frequencies more like condensers than like conductors having fixed resistance and inductance and no capacity. Since a coil constructed in the usual way behaves for high frequencies as a conductor having distributed resistance, inductance, and capacity, it follows that such a coil will show for high frequencies the same quasi-resonance as is observed with low frequencies in long aerial lines and cables—*i. e.*, that it will *per se* and without the intermediary of a condenser show a slight degree of selectivity for some particular frequency and for certain multiples of that frequency just as a stretched string which has distributed inertia and elasticity will respond to a particular tone called its "fundamental" and to all other tones whose periods are aliquot parts of the periods of that fundamental; but it is not with such quasi-resonance that the present invention is carried into effect, and I wish it understood that I here disclaim any system employing distributed inductance and capacity as a means of tuning the resonant circuits described in this specification.

A general criterion which determines the utility of a coil for tuning a circuit to a particular high frequency is that the potential energy of the displacement-currents in the coil shall be small compared to the kinetic energy of the conduction-current flowing through the coil when the coil is traversed by a current of that frequency.

I have found that for a single-layer coil the following procedure is sufficient for practical purposes. Determine the inductance of the coil by formulæ to be found in the text-books and treatises on electricity and magnetism. This will enable the kinetic energy of the coil to be determined for any particular current and will also permit of the determination of what would be the potential gradient along the coil for the current of the frequency to be employed if the coil were devoid of distributed electrostatic capacity. Next calculate the electrostatic capacity between an end turn and each of the remaining turns of the coil. These capacities, together with the potential gradient found, will enable the potential energy to be determined, and if the ratio of the potential energy to the kinetic energy so found be negligible compared to unity the coil will practically satisfy the requirements hereinbefore mentioned. If the coil does not meet the requirements, the design should be so changed as to increase the separation between the turns or the size of the wire should be diminished or the dimensions of the coil so otherwise altered as to decrease the distributed capacity without proportionately diminishing the inductance. The calculations may be greatly abbreviated and the liability to error greatly reduced if the results of the computations be plotted in curves.

Regarding the effect of a dielectric core in a coil to be used for tuning a circuit to a high frequency, it is sufficient to state that the preferred form of support for such a coil is any skeleton frame which will hold the turns of wire in place without exposing much surface of contact to the wires and affording a minimum of opportunity for the development of displacement-currents within itself.

In this specification I have spoken of elevated conductors, vertically-elevated conductors, and vertical conductors. I wish to be understood as including in the term "elevated" conductors disposed at an angle to the earth's surface as distinguished from horizontal conductors disposed parallel to the earth's surface. By the terms "vertically elevated" and "vertical" I refer to conductors whose disposition with regard to the earth's surface is mainly or wholly at a right angle or vertical thereto, which is the particular form of elevated conductor preferred by me for use in connection with my present improvement.

In this specification I have described the development of free or unguided electromagnetic signal-waves of a given frequency by employing in association with an elevated conductor a circuit such as to produce therein forced simple harmonic electric vibrations of the frequency desired. I have also described a method of receiving or absorbing the energy of free or unguided simple harmonic electromagnetic waves of one frequency to the exclusion of waves of a different frequency by associating with an elevated conductor a circuit made resonant to the frequency of the waves whose energy is to be absorbed. The circuit whereby forced simple harmonic electric vibrations are produced in the elevated conductor I have shown as a circuit containing a condenser and a self-induction coil so proportioned as to make the natural vibrations of a frequency which is the frequency of the vibrations to be forced or impressed in an elevated conductor. The circuit whereby the energy of the electromagnetic waves of one frequency is absorbed to the exclusion of that of waves of another frequency is in like manner a circuit containing a condenser and a self-induction coil so proportioned as to make the circuit resonant to a frequency which is the frequency of the waves the energy of which is to be received. Both of the circuits I have spoken of are tuned circuits, and they may be conveniently distinguished with reference to their respec-

tive functions by denominating the circuit employed in the development of the vibrations as an "oscillating" or "sonorous" circuit and by denominating the circuit employed in the reception or absorption of the vibrations as a "resonant" circuit. I prefer to make this discrimination in nomenclature for the reason that while both the circuits are resonant circuits, yet time only only that one employed for receiving or absorbing is accurately so described. Except for this distinction in function it is well to note that all oscillating or sonorous circuits are resonant circuits, but only such resonant circuits as have their resistance less than the square root of the ratio of four times their inductance by their capacity are oscillating or sonorous circuits.

Also throughout this specification I have described the electrical oscillations or vibrations and the free or unguided electromagnetic waves or radiations as simple harmonic. It is the object of my present invention to approach as nearly as possible to the perfect simple harmonic wave and such object is attained to within such a degree of precision as to preclude any possible interference with the operation of the system by any departure that can exist in the wave from the absolute simple harmonic form. My reason for confining the description of the electrical oscillations or vibrations and the electromagnetic waves or radiations to the simple harmonic type is that in the operation of the system only simple harmonic waves and vibrations are effective in carrying out the object of the invention. If in any similar system of selective space telegraphy there be frequent, even minute, overtones accompanying the simple harmonic signal waves, such overtones will not only not contribute to the useful operation of the system, but may, in fact, become obstacles to such useful and complete operation. It is for this reason that I have taken every precaution to obtain a true or absolute simple harmonic wave form.

Specifically, though it may be possible to employ for the purpose of multiple and selective wireless telegraphy electric vibrations and radiations departing considerably from the simple harmonic type by employing at the receiving end circuits selective to the fundamental of such vibrations and radiations, yet it will only be through the selective reception of that simple harmonic component of the vibrations or radiations which is their fundamental that the system will be operative. The other simple harmonic components of the vibrations or radiations add nothing to the operation of the system. Moreover, if such overtones exist in the waves emanating from a transmitting station their presence will preclude the possibility of placing receiving stations in the immediate neighborhood of such transmitting station for the reception of signal waves of frequencies corresponding to the frequencies of such overtones.

Whereas in the present specification I have used the term "elevated" conductor to describe the source of radiation of electromagnetic waves developed by forced electric vibrations impressed thereon, yet I deem it proper to point out that this expression should not be confused with the term "conductor" when used in connection with systems wherein that term is employed to denote a wire or other metallically continuous conductor extending from a transmitting to a receiving station. It is of course obvious that in the art to which the present specification relates such a conductor is wholly absent. The vertical metallically continuous source of radiant energy is a structure the location and function of which are confined entirely to the transmitting, or it may be to the receiving, end of a system in which the conductor which connects the transmitting and receiving stations is the non-metallic non-conducting—in fact, dielectric—medium, which is commonly called the "ether" and which is by many assumed to be essential to the theory of the propagation of electrical and magnetic forces, radiant light, and radiant heat.

Having described my invention, I claim—

1. In a system for developing free or unguided simple harmonic electromagnetic signal waves of a definite frequency, an elevated conductor and means for developing therein forced simple harmonic electric vibrations of corresponding frequency.

2. In a system for receiving the energy of free or unguided simple harmonic electromagnetic signal waves of a definite frequency, to the exclusion of the energy of signal waves of other frequencies, an elevated conductor and a resonant circuit associated with said conductor and attuned to the frequency of the waves, the energy of which is to be received.

3. In a system for independently developing free or unguided simple harmonic electromagnetic signal waves of different frequencies, an elevated conductor and means for independently developing therein forced, simple harmonic, electric vibrations of different and corresponding frequencies.

4. In a system for selectively receiving the energy of free or unguided, simple harmonic, electromagnetic signal waves of different frequencies, each to the exclusion of the rest, an elevated conductor, and resonant circuits associated with said conductor and each attuned to the frequency of a different one of the trains of waves, the energy of which is to be received.

5. In a system for independently developing free or unguided simple harmonic, electromagnetic signal waves of different frequencies, a plurality of elevated conductors corresponding to the number of said different frequencies, and means for impressing upon each

of said conductors forced simple harmonic electric vibrations corresponding to a different one of the said frequencies.

6. In a system for selectively receiving the energy of free or unguided simple harmonic, electromagnetic signal-waves of different frequencies, a plurality of elevated conductors corresponding in number to the number of different frequencies to be received, and resonant circuits each associated with a different elevated conductor, and each attuned to a different one of the said frequencies.

7. In a system for producing free and unguided electromagnetic signal-waves of a definite frequency, an elevated conductor, a source of electrical energy and a group of resonant circuits interposed between said elevated conductor and said source of electrical energy, said circuits being attuned to the frequency of the waves to be developed.

8. In a system for receiving the energy of free or unguided simple harmonic, electromagnetic signal-waves of one frequency to the exclusion of the energy of those of other frequencies, an elevated conductor, an electric translating device, and a group of resonant circuits interposed between said elevated conductor and said electric translating device, said circuits being resonant to the frequency of the waves, the energy of which is to be received.

9. In a system for developing free or unguided simple harmonic, electromagnetic signal-waves, a condenser, means for charging and discharging said condenser through a closed circuit having inductance adapted to produce under such conditions simple harmonic electric vibrations, and means for communicating the vibrations so produced to an open circuit or elevated conductor.

10. In a system for developing free or unguided, simple harmonic, electromagnetic signal-waves, a condenser, means for charging and discharging said condenser through a closed circuit having inductance adapted to produce under such conditions simple harmonic electric vibrations, means for communicating said vibrations to a resonant circuit or group thereof attuned to the frequency of these vibrations and means of communicating the resulting electrical vibrations in said resonant circuit or group thereof to an open circuit or elevated conductor.

11. A circuit resonant to a given high frequency comprising a coil having the amplitude of its potential energy small compared to the amplitude of its kinetic energy when it is supporting a current of said given high frequency, and a condenser adapted to balance by its reactance, the reactance of said coil for said given high frequency.

12. In a circuit resonant to a given high frequency, a coil having the amplitude of its potential energy small compared to the amplitude of its kinetic energy when supporting a current of said given high frequency.

13. In a system for selectively receiving the energy of free or unguided simple harmonic electromagnetic signal-waves of different frequencies, an elevated conductor, and a plurality of resonant circuits associated with said elevated conductor, each resonant to the particular frequency of the electromagnetic waves, the energy of which it is to receive.

14. In a system for selectively receiving the energy of free or unguided simple harmonic, electromagnetic, signal-waves of different frequencies, a plurality of elevated conductors, each associated with a circuit resonant to the particular frequency of the electromagnetic waves, the energy of which it is to receive.

15. In a system for selectively receiving the energy of free or unguided simple harmonic, electromagnetic, signal-waves of different frequencies, a plurality of elevated conductors, each associated with a group of circuits resonant to the particular frequency of the electromagnetic waves the energy of which it is to receive.

16. In a system for selectively receiving the energy of free or unguided simple harmonic, electromagnetic signal-waves of different frequencies, an elevated conductor and a plurality of groups of resonant circuits associated with said elevated conductor, each of said groups of circuits being resonant to the particular frequencies of the electromagnetic waves, the energy of which it is to receive.

17. In a system for receiving the energy of free or unguided, simple harmonic, electromagnetic signal-waves of a definite frequency to the exclusion of energy of signal-waves of other frequencies, an elevated conductor and a group of resonant circuits associated with said conductor and attuned to the frequency of the waves, the energy of which is to be received.

18. In a system for selectively receiving the energy of free or unguided, simple harmonic, electromagnetic signal-waves of different frequencies, each to the exclusion of the rest, an elevated conductor and a plurality of resonant circuits associated with said conductor and each attuned to the frequency of a different one of the trains of waves, the energy of which is to be received.

19. In a system for selectively receiving the energy of free or unguided simple harmonic, electromagnetic signal-waves of different frequencies, a plurality of elevated conductors corresponding in number to the number of different frequencies to be received, and groups of resonant circuits each associated with a different elevated conductor, and each attuned to a different one of the said frequencies.

20. In a system for developing free or unguided simple harmonic, electromagnetic signal-waves or radiations, an elevated conductor, associated closed oscillating circuits, means for disturbing the electrical equilibrium of said oscillating circuits, and means for swamping the effect of the mutual inductance between said circuit and the elevated conductor.

21. In a system for independently developing free or unguided electromagnetic signal-waves or radiations of different frequencies, an elevated conductor, associated closed oscillating circuits each attuned to a different one of the frequencies to be developed, and each of said oscillating circuits having sufficient auxiliary inductance to swamp the effect of the mutual inductance between it and the other oscillating circuits and between it and the elevated conductor.

22. In a system for receiving the energy of simple harmonic, electromagnetic waves of a given frequency, to the exclusion of like waves of different frequencies, an elevated conductor, a circuit associated with said elevated conductor and made resonant to the frequency of the electromagnetic waves, the energy of which is to be received, by the condenser and an auxiliary inductance-coil whose inductance is sufficient to swamp the effect of the mutual inductance between the associated circuit and the elevated conductor.

23. In a system for receiving the energy of simple harmonic, electromagnetic waves of one frequency, to the exclusion of like waves of different frequencies, an elevated conductor, associated circuits each resonant to the frequency of the electromagnetic waves to be received, and each having sufficient auxiliary inductance to swamp the effect of the mutual inductance between it and the other associated circuits and between it and the elevated conductor.

24. In a system for developing simple harmonic, electromagnetic signal-waves or radiations of a given frequency, a metallically-continuous vertical oscillator and means for impressing thereon simple harmonic, electrical, oscillations of the same frequency.

25. In a system for simultaneously developing simple harmonic, electromagnetic, signal waves of different frequencies, a metallically-continuous vertical oscillator, and means for impressing thereon simple harmonic, electrical oscillations of the same frequencies.

26. In a system for receiving the energy of free or unguided, simple harmonic, electromagnetic waves, an elevated conductor, a circuit associated with said elevated conductor and resonant to the frequency of the electromagnetic waves, and an electric translating device shunted around the terminals of one of the elements of said resonant circuit.

27. In a system for receiving the energy of free or unguided, simple harmonic, electromagnetic waves, an elevated conductor, a group of resonant circuits associated with said resonant conductor, resonant to the frequency of the electromagnetic waves, and an electric translating device shunted around terminals of that one of said resonant circuits which is farthest removed from the elevated conductor.

28. In a system for receiving the energy of free or unguided, simple harmonic, electromagnetic waves, an elevated conductor and an electric translating device forming one of the elements of a resonant circuit associated with said elevated conductor and resonant to the frequency of the electromagnetic waves.

29. In a system for receiving the energy of simple harmonic, electromagnetic waves of a given frequency, to the exclusion of like waves of different frequencies, an elevated conductor, a circuit associated with said elevated conductor and made resonant to the frequency of the electromagnetic waves, the energy of which is to be received, and means for swamping the effect of the mutual inductance between said circuit and the elevated conductor.

30. In a system for receiving the energy of simple harmonic, electromagnetic waves of one frequency, to the exclusion of like waves of different frequencies, an elevated conductor, associated circuits each resonant to the frequency of the electromagnetic waves to be received, and means in each of said circuits for swamping the effect of the mutual inductance between it and the other circuits and between it and the elevated conductor.

31. In a system for receiving the energy of free or unguided, simple harmonic, electromagnetic signal waves of a definite frequency, to the exclusion of the energy of signal-waves of other frequencies, an elevated conductor, a resonant circuit associated with said conductor and attuned to the frequency of the waves, the energy of which is to be received, and means for swamping the effect of the mutual inductance between said circuit and the elevated conductor.

32. In a system for selectively receiving the energy of free or unguided, simple harmonic, electromagnetic signal-waves of different frequencies, each to the exclusion of the rest, an elevated conductor, resonant circuits associated with said conductor and each attuned to the frequency of a different one of the trains of waves, the energy of which is to be received, and means for swamping the effect of the mutual inductance between said circuit and the elevated conductor.

33. In a system for selectively receiving the energy of free or unguided, simple harmonic electromagnetic signal-waves of different frequencies, a plurality of elevated conductors corresponding in number to the number of different frequencies to be received, resonant circuits each associated with a different elevated conductor and each attuned to a different one of the said frequencies, and means in each of said circuits for swamping the effect of the mutual inductance between it and the other circuits and between it and the elevated conductor.

34. In a system for producing free and unguided electromagnetic signal-waves of a definite frequency, an elevated conductor, a source of electric energy, a group of resonant circuits interposed between said elevated conductor and said source of electric energy, said circuits being attuned to the frequency

of the waves to be developed, and means in each of said circuits for swamping the effect of the mutual inductance between it and the other circuits and between it and the elevated conductor.

35. In a system for receiving the energy of free or unguided, simple harmonic, electromagnetic signal-waves of one frequency, to the exclusion of the energy of those of other frequencies, an elevated conductor, an electric translating device, a group of resonant circuits interposed between said elevated conductor and said electric translating device, said circuits being resonant to the frequency of the waves, the energy of which is to be received, and means in each of said circuits for swamping the effect of the mutual inductance between it and the other circuits and between it and the elevated conductor.

36. In a system for developing free or unguided, simple harmonic, electromagnetic signal-waves, a condenser, means for charging and discharging said condenser through a closed circuit having inductance adapted to produce under such conditions simple harmonic, electric vibrations, means for communicating the vibrations so produced to an elevated conductor, and means for swamping the effect of the mutual inductance between said circuit and the elevated conductor.

37. In a system for developing free or unguided, simple harmonic, electromagnetic signal-waves, a condenser, means for charging and discharging said condenser through a closed circuit having inductance adapted to produce under such conditions simple harmonic, electric vibrations, means for communicating said vibrations to a resonant circuit or group thereof attuned to the frequency of these vibrations, means of communicating the resulting electrical vibrations in said resonant circuit or group thereof to an elevated conductor, and means in each of said circuits for swamping the effect of the mutual inductance between it and the other circuits and between it and the elevated conductor.

38. In a system for selectively receiving the energy of free or unguided, simple harmonic, electromagnetic signal-waves of different frequencies, an elevated conductor, a plurality of resonant circuits associated with said elevated conductor, each resonant to the particular frequency of the electromagnetic waves, the energy of which it is to receive, and means in each of said circuits for swamping the effect of the mutual inductance between it and the other circuits and between it and the elevated conductor.

39. In a system for selectively receiving the energy of free or unguided, simple harmonic, electromagnetic signal-waves of different frequencies, a plurality of elevated conductors, each associated with a circuit resonant to the particular frequency of the electromagnetic waves, the energy of which it is to receive, and means in each of said circuits for swamping the effect of the mutual inductance between it and the other circuits and between it and the elevated conductor.

40. In a system for selectively receiving the energy of free or unguided, simple harmonic, electromagnetic signal-waves of different frequencies, a plurality of elevated conductors, each associated with a group of circuits resonant to the particular frequency of the electromagnetic waves the energy of which it is to receive, and means in each of said circuits for swamping the effect of the mutual inductance between it and the other circuits and between it and the elevated conductor.

41. In a system for selectively receiving the energy of free or unguided, simple harmonic, electromagnetic signal-waves of different frequencies, an elevated conductor, a plurality of groups of resonant circuits associated with said elevated conductor, each of said groups of circuits being resonant to the particular frequencies of the electromagnetic waves, the energy of which it is to receive, and means in each of said circuits for swamping the effect of the mutual inductance between it and the other circuits and between it and the elevated conductor.

42. In a system for receiving the energy of free or unguided, simple harmonic, electromagnetic signal-waves of a definite frequency, to the exclusion of energy of signal-waves of other frequencies, an elevated conductor, a group of resonant circuits associated with said conductor attuned to the frequency of the waves, the energy of which is to be received, and means in each of said circuits for swamping the effect of the mutual inductance between it and the other circuits and between it and the elevated conductor.

43. In a system for selectively receiving the energy of free or unguided, simple harmonic, electromagnetic signal-waves of different frequencies, each to the exclusion of the rest, an elevated conductor, a plurality of resonant circuits associated with said conductors and each attuned to the frequency of a different one of the trains of waves, the energy of which is to be received, and means in each of said circuits for swamping the effect of the mutual inductance between it and the other circuits and between it and the elevated conductor.

44. In a system for selectively receiving the energy of free or unguided, simple harmonic, electromagnetic signal-waves of different frequencies, a plurality of elevated conductors corresponding in number to the number of different frequencies to be received, groups of resonant circuits each associated with a different elevated conductor, and each attuned to a different one of the said frequencies, and means in each of said circuits for swamping the effect of the mutual inductance between it and the other circuits and between it and the elevated conductor.

APPLICATION FOR LETTERS PATENT.

PETITION.

To the Commissioner of Patents:

Your Petitioner

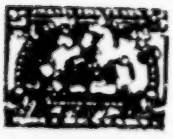
residing

P. O. address, 2 Newbury St. Boston, Mass.

prays that Letters Patent may be granted to him

for the set forth in the annexed specifications and hereby appoints as his authorized attorney ALEX P. BROWNE, of No. 31 State Street, Boston, Mass.,

with full power of substitution and revocation to prosecute this application, to make alterations and amendments therein, to receive the patent and to transact all business in the Patent Office connected therewith.



John Stow Shaw

SPECIFICATION.

TO ALL WHOM IT MAY CONCERN:

Be it known that

My invention relates to the art of transmitting intelligence from one station to another by means of electro-magnetic waves without the use of wires to guide the waves to their destination, and it relates more particularly to the system of transmission in which the electro-magnetic waves are developed by producing electric vibrations in an elevated conductor, preferably vertically elevated.

In practice in signalling between two stations by means of electro-magnetic waves, when the stations are not connected by a conducting wire, certain disadvantageous limitations have been observed which greatly militated against the commercial value of the methods employed. When the electro-magnetic waves are developed by producing natural or forced electric vibrations in a horizontal conductor, the attenuation of the waves so developed as they travel away from the conductor, is found to be so great as to very seriously limit the distance to which they may be transmitted and effectively received, the chief cause of this observed phenomenon probably being that owing to the horizontal position of the conductor, the plane of polarization of the waves is such as to cause the rapid absorption of the energy of the waves by the conducting surface of the earth or water over which they travel. This difficulty has been overcome by a method of developing the waves which consists in producing natural electric vibrations in a vertically elevated conductor, in which case the plane of polarization of the wave so produced is at quadrature with that of the waves which may be developed by a horizontal wire, and in case of the vertical conductor the attenuation of the waves is observed

be very much less than in the case of the horizontal conductor so that these waves may be transmitted to, and effectively received at much greater distances.

A limitation of the commercial utility of this system is however observed which depends upon the fact that it has not heretofore been found possible, so far as I am aware, to direct signals sent out from a transmitter station to the particular receiving station with which it is desired to communicate to the exclusion of other receiving stations equipped with equally or more sensitive receiving apparatus and located within the radius of influence of the sending station.

Electro-magnetic waves have also been developed by producing natural or forced electric oscillations in loops or coils of wire at the transmitting station and also by means of the discharge of electricity between two conducting spheres, cylinders, or cones, but in such cases, the sphere of influence is so limited as to greatly restrict the commercial utility these two methods of developing the signal waves.

In fine, the method of signalling by means of electro-magnetic waves between stations not connected by a conducting wire, in which method the electro-magnetic waves are developed by electric vibrations in an elevated conductor, has great advantages over the other existing or proposed methods for accomplishing this purpose in which the electro-magnetic waves are developed by other means since in the case of the waves developed by the elevated conductor method, the waves may be transmitted to and effectively received at greater distances than by the other systems. But whereas in the systems employing the other methods of generating the waves, the signals de-

veloped may, at least theoretically, be directed to the particular receiving station with which it is desired to communicate to the exclusion of other similar receiving stations in the neighborhood; it has been proposed, for example, that as I know, to accomplish this purpose in the system of the above-mentioned character, the electrical oscillations are caused to be propagated in the form of electromagnetic waves.

The object of this invention is to overcome the above-mentioned limitation to the [illegible] waves [illegible]

[illegible]

[illegible]

[

mately restore the condition of electrical equilibrium. These currents may be either unidirectional or oscillatory in character, depending upon the relation between the principal electro-magnetic constants of the conductor, i.e., upon its electromagnetic and electro-static capacities and its resistance. These phenomena are analogous to the mechanical pehnomena which are observed when the mechanical equilibrium of a system is abruptly disturbed and the system is thereafter left to itself. In the case of a mechanical system, motions result which tend to restore the mechanical equilibrium of the system. These motions may consist either of a unidirectional displacement or of to and fro vibrations of the system or parts of the system, depending upon the relations which subsist between the principal mechanical constants of the system, i.e., its moments of mass and elasticity and its friction coefficients. In general, the determination of the relations which must subsist in order that an oscillatory restoration of equilibrium shall take place, either in an electric or in a mechanical system, the determination of the period of these oscillations is very difficult, but in certain simple cases both the determination of the conditions for an oscillatory restoration of equilibrium, and of the period of these oscillations is quite simple.

An example of a simple mechanical system capable of oscillatory restoration of equilibrium is to be found in the torsional pendulum, which consists of a highly elastic wire fixed at one end and supporting at its other extremity a mass called the bob. If a torsional stress be impressed upon the wire of this pendulum by turning the bob about the axis of the wire and the bob be then abruptly released, the pen-

in general execute isochronous oscillations about the axis of the suspending wire in the process of restoration of equilibrium. An example of a simple electrical system capable of an oscillatory restoration of equilibrium is to be found in the case of a circuit consisting simply of a condenser and a coil without iron in its core as shown in Fig.1 of the accompanying drawings in which C is a condenser and I is a coil without iron in its core. If a charge of electricity be imparted to the condenser and if its electrodes be then connected to the coil as shown in Fig.1, an isochronous oscillatory current will in general be developed in the circuit in the process of restoration of its electrical equilibrium. Such a simple circuit as that shown in Fig.1 is known as a system with a single degree of freedom, and the electric oscillations which it supports when its equilibrium is abruptly disturbed and it is then left to itself are known as the natural vibrations or oscillations of the system. These vibrations begin with a maximum of amplitude and gradually die away in accordance with what is known as an exponential law, and are what are known as simple harmonic vibrations. They may be represented graphically as in Fig.2, in which A is a curve drawn to rectangular coordinates in which the ordinates represent instantaneous values of current strength and the abscissae represent times.

When two such simple circuits are associated together, inductively as shown in Fig.3, the system so formed is known as a system of two degrees of freedom and in the oscillatory restorations of equilibrium, i.e., in the natural vibrations in such circuits, the currents are in general not simple harmonic in character but in general consist of the superposition of

two simple harmonic currents as shown in Fig.4.

In general, if n simple circuits as shown in Fig.1 be associated together in a system either by conductive or by inductive connections, a system of at least n degrees of freedom results and the natural oscillations of such a system will therefore consist of the superposition of at least n currents. It is moreover a fact that the different simple harmonic components of the oscillations which together constitute the oscillatory restoration of equilibrium of a complex system are in general not the same as those of the separate simple circuits when these circuits are isolated from one another, but the presence of each simple circuit modifies the natural period of each of the other circuits with which it is associated. Thus in a particular case if there be two simple circuits, the first with a natural period of .004 of a second when isolated and the second with a period of .0025 of a second when isolated; these circuits when inductively connected as shown in Fig. 4 will have an oscillatory restoration of equilibrium of which the simple harmonic components are .0044 of a second, and .0014 of a second, showing that the inductive association of the circuits together has increased the natural period of the higher frequency circuit, and decreased the natural period of the lower frequency circuit. It is moreover to be remembered that during the restoration of electric equilibrium currents of each of the periods are found in each of the circuits of the connected system.

So far we have considered the natural vibrations of electric systems, i.e., the electric vibrations by means of which the electric equilibrium of circuits is restored after it has been abruptly destroyed and the circuits are left to themselves and we have compared the simple case of mechanical electric

vibrations with the corresponding natural mechanical vibrations or mechanical systems. We have seen that simple circuits may have simple harmonic natural electric oscillations, and that complex circuits will in general, have complex oscillations. We have moreover seen that the natural oscillations depended upon the electro-magnetic constants of the circuit in the case of a simple circuit and that the periods of oscillation in the case of a complex or interrelated circuits depended upon the electro-magnetic constants of each of the interrelated circuits. But besides the power to execute natural vibrations or oscillations, both electrical and mechanical systems are capable of supporting what are called forced vibrations and in the case of forced vibrations the period of the vibration is independent of the electrical constants of the circuit on the one hand, and the mechanical constants of the mechanical system on the other hand, and depends only upon the period of the impressed force. Thus if a simple harmonic electro-motive force be impressed upon a circuit free from hysteresis, whether it be a simple circuit or a complex of simple circuits, the forced vibrations or currents resulting from this impressed force will also be simple harmonic, and of the same period as that of the impressed force.

In the present system of signalling by means of electro-magnetic waves in which a vertical conductor is employed as the source of electro-magnetic radiations, the electric oscillations hereinbefore described as natural vibrations of the conductor being charged to a high potential and the surrounding earth and permitted to absorb the energy of an electric spark be-

tween two ball electrodes.

In such a method of developing the electro-magnetic waves, the oscillations are necessarily of a complex character and therefore the resulting electro-magnetic waves are of a complex character and consist of a great variety of superimposed simple harmonic vibrations of different frequencies. The vibrations consist of a simple harmonic vibration of lower period than all the others, known as the fundamental with a great variety of simple harmonics of higher periodicity superimposed thereon. Similarly the vertical conductor at the receiving station is capable of receiving and responding to vibrations of a great variety of frequencies so that the electro-magnetic waves which emanate from one vertical conductor used as a transmitter are capable of exciting vibrations in any other vertical wire as a receiver and for this reason, any transmitting station in a system of this character will operate any receiving-station within its sphere of influence and the messages from the transmitting station will not be selectively received by the particular receiving station with which it is desired to communicate but will interfere with the operation of other receiving stations within its sphere of influence, thereby preventing them from properly responding to the signals of the transmitting stations from which they are in order to receive their signals.

By my invention the vertical conductor of the transmitting station is made the source of electro-magnetic waves of a single periodicity, and the translating apparatus of the receiving station is caused to be selectively responsive to waves of but a single period to the exclusion

apparatus corresponds to a tuning fork sending but a single simple musical tone, and the receiving apparatus corresponds to an acoustic resonator capable of absorbing the energy of that single, simple musical tone only.

When the apparatus at a particular station is attuned to the same periodicity as that of the electro-magnetic waves emanating from a particular transmitting station, then this receiving station will respond to and be capable of selectively receiving messages from that particular transmitting station, to the exclusion of messages simultaneously or otherwise sent from other transmitting stations in the neighborhood which generate electro-magnetic waves of different periodicities. Moreover, by my invention the operator at the transmitting or receiving station may at will adjust the apparatus at his command in such a way as to place himself in communication with any one of a number of stations in the neighborhood, by bringing his apparatus into resonance with the periodicity employed at the station with which intercommunication is desired.

In order that the vertical conductor at the transmitting station shall generate harmonic electro-magnetic waves of but one frequency, I cause the electric vibrations in the conductor to be of a simple harmonic character and this in turn I effect by producing what are substantially forced electric vibrations in the vertical conductor in lieu of producing natural vibrations in the conductor as has heretofore been practiced. In the electric transmitting apparatus at the receiving station which is to be operated only by electric waves of a certain periodicity and by no others, I interpose between the

vertical conductor at the receiving station and the translating devices, resonant circuits attuned to the particular frequency of the electro-magnetic waves which it is desired to have operate the translating devices.

Having thus described broadly, the nature and object of the invention and the electrical principles upon which it is based, the details of the invention may best be described by having reference to the drawings which accompany and form a part of this specification. The same letters, so far as may be, represent similar parts in all the figures.

Figures 1 to 4 are diagrams already referred to.

Fig. 5 is a diagram illustrating one arrangement of transmitting station.

Fig. 6 is a diagram illustrating an arrangement of receiving station.

Fig. 7 is a diagram illustrating another form of transmitting station.

Fig. 8 is a diagram illustrating another form of receiving station.

Figs. 9 and 13 are diagrams illustrating a detail of tion at both transmitting and receiving stations.

Figs. 10 and 11 are diagrams illustrative of tion of the coherer at receiving stations.

Fig. 12 is a diagram illustrating the telephone at the receiving station.

In the drawings V represents vertical conductor grounded at

M, M' and M'' are induction coils, the primary coils are I, I' and I'' and

L, L' and L'' are auxiliary inductance coils.

C, C' and C'' are electrical condensers.

K is a coherer.

B is an electric battery.

a is an alternating current generator

T is a circuit closing key.

R is a telegraphic relay or other suitable electric translating device.

B is an automatic circuit interrupter.

s is a spark gap

In the organization illustrated in Fig. 5 the generator a develops an alternating electro-motive force of moderate frequency which when the key k is depressed develops a current in the primary circuit of the transformer M'. The transformer M' is so designed as to transform the electro-motive force in the primary circuit to a very high electro-motive force in the secondary. As the potential difference at the terminals of the secondary L' rises, the charge in the condenser C increases till the potential difference is sufficient to break down the dielectric at the spark gap s. When this occurs, the condenser C discharges through the spark at s the primary I, and the inductance coil L. This discharge is oscillatory in character and of very high frequency as will be explained hereafter. The high frequency current so developed passing through the primary I, induces a corresponding high frequency electro-motive force and current in the secondary I, and forced electric vibrations result in the vertical conductor v, which are practically of a simple harmonic character. These simple harmonic [illegible] in the conductor v develop electro-magnetic waves,

which are also practically simple harmonic in character and these in turn on impinging upon the vertical conductor at the receiving station develop therein corresponding simple harmonic vibrations of like frequency.

In the organization illustrated in Fig. 8 [redacted] monic electro-magnetic waves of a given frequency or periodicity impinging upon the vertical conductor v develop [redacted] corresponding electrical vibrations of like frequency. By means of the induction coil H, a vibratory electro-motive force corresponding in frequency to the electric vibrations in the conductor v is induced in the secondary circuit I, L, C, C', If the frequency of this induced electro-motive force is that to which the circuit I, L C C' is attuned, there will be a maximum potential difference developed at the plates of the condenser C, and this potential will operate the coherer K. When the coherer K operates, the resistance of the circuit B R K is enormously diminished and the battery B develops a current which operates the translating device R. The decoherer, not shown in the drawing, is thereby set in operation and as soon as the impulse passes, the coherer is restored to its sensitive condition. If however the frequency of the electro-magnetic waves which impinge upon the vertical conductor v of the receiving station depicted in Fig. 8 is not the same as that to which the circuit I, L C C' is attuned, the electro-motive force induced in this circuit will be different from that to which the circuit will respond by virtue of resonance, and there will be but a negligible potential difference developed at the plates of the condenser C. Under these circumstances the coherer K will not be operated and the signals will not actuate the translating device R.

When transmitting stations and a corresponding number of receiving stations are employed, by adjusting the electro-magnetic constants of the circuits at the various receiving stations, these circuits may be so proportioned or tuned that the energy of the electro-magnetic waves emanating from any given transmitting station will be selectively received and absorbed at a given receiving station.

Before proceeding to a description of the operation of the other two forms of transmitting and receiving stations shown in Figs. 7 and 8, it is to be noted that the condenser C in Fig. 5 discharges through the circuit s I, L, and its discharge is practically unaffected by its conductive connection with the circuit through I'_2. The reason for this is that the impedance offered by the circuit through I'_2 is enormously greater than that through s I, L. Also the discharge through the circuit s I, L is of very great frequency because the frequency of the oscillations of such discharges of condensers is approximately inversely proportional to the square root of the product of the inductance of the circuit by the capacity of the condenser and for the purpose of this invention the apparatus is so designed that the product of the capacity of the condenser by the inductance of the circuit is made numerically very small. Moreover the oscillations in the circuit s I, L are approximately simple harmonic in character and are practically unaffected by the inductive association with the vertical wire because of the auxiliary inductance furnished by the coil I, it being capable of demonstration that if by means of the coil L, the inductance of the circuit L I, s is rendered large compared the mutual inductance between the circuit and the vertical

wire, the natural oscillations which will take place in the circuit s I, L will be practically unaffected by the inductive association with the vertical wire and will therefore be practically of a simple harmonic character as in the case of the isolated simple circuit shown in Fig.1. The principle may, for the present purpose, be stated thus:- That when two simple oscillators, each such as that shown in Fig.1, are inductively associated with each other as in Fig.3, the system is a system of two degrees of freedom, and the natural period of oscillation of each simple circuit is modified by the presence of the other, but if the proportions of the circuits be such that the product of the inductances of the two circuits is large compared to the mutual inductance between the circuits, the natural period of oscillation of each of the circuits becomes practically the same as if the circuits were isolated. If further, the electric equilibrium of the circuit s I, L be abruptly disturbed and the circuit be then left without impressed force, the oscillations which are developed in it induce corresponding oscillations in the vertical wire, which oscillations are virtually forced vibrations, corresponding in frequency with the natural oscillations developed in the circuit s I, L and being practically independent, as regards their frequency, of the constants of the second circuit in which they are induced.

It is to be understood that any suitable device may be employed to develop the simple harmonic force impressed upon the vertical wire. It is sufficient to develop in the vertical wire practically simple harmonic vibrations of a fixed and high frequency.

At the receiving station shown in Fig.6 the inductance coil L is introduced in order to supply auxiliary inductance and to permit of the ~~current~~ circuit C C' I, L being attuned to a particular frequency practically independently of the constants of the vertical wire.

In both the organizations illustrated in Figs.5 and 6, the inductance coils L may be made adjustable and serve as a means whereby the operators may adjust the apparatus to the particular frequency which it is intended to employ.

Passing now to the organizations illustrated in Figs.7 and 8, it is to be noted that they differ respectively from those illustrated in Figs.5 and 6 in that additional resonant circuits C I' L I, are interposed between the vertical conductor and the generating and translating devices respectively.

In the transmitter arrangements illustrated in Fig.7, the circuit C I' L I, is attuned to the same period as the circuit C' L' I', s and merely tends to weed out and thereby screen the vertical wire from any harmonics which may exist in the current developed in the circuit C' L' I', s. This screening action of an interposed resonant circuit is due to the well known property of such circuits by which a resonant circuit favors the development in it of simple harmonic currents of the period to which it is attuned and strongly opposes the development in it of simple harmonic currents of other periodicities. In this organization an ordinary spark coil, shown at M', equipped in the usual way with an interrupter p and condenser C' is employed, the current being supplied by the battery B. The operation of this organization is substantially the same as that of the organization shown in Fig.5, hereinbefore described, except for the screening action

of the circuit C I' L I, and need not therefore be further described. Suffice it to say that when the source of vibratory currents is particularly rich in harmonics any suitable number of resonant circuits, each attuned to the desired frequency may be connected inductively in series, as shown in Figs. 9 and 10, and interposed between the generating device and the vertical conductor for the purpose of screening the vertical conductor from the undesirable harmonics.

In the organization illustrated in Fig.8, the electric resonator C I' L I, interposed between the vertical conductor and the circuit containing the coherer is attuned to the same period as the circuit L' C' C" I', and acts to screen the coherer circuit from the effect of all currents developed in the vertical conductor save that of the current of the particular period to which the receiving station is intended to respond. As in the case of the transmitting station, any suitable number of resonant circuits, each attuned to the particular period to which the station is desired to respond may be connected as shown in Figs. 9 and 10, and interposed between the vertical conductor and the coherer circuit. Such circuits so interposed serve to screen the receiver from the effect of all currents which may be induced in the vertical conductor that are not of the period to which the receiving station is intended to respond.

No mention has heretofore been made of the function of the condensers shown at C' in Fig.6 and at C" in Fig.8, as those condensers are not essential to the tuning of the circuits in which they are placed, but merely serve to exclude the current of the batteries B from the resonant circuits. In or-

der that these condensers may not appreciably affect the tuning of the circuits in which they are included and thereby lower the resonant rise of potential at the plates of the condensers C and C', shown in Figs. 6 and 8, they are so constructed as to have large capacities compared to the capacities of C and C' in Figs. 6 and 8 respectively.

In Figs. 6 and 8, the coherers K are shown connected in shunt circuit to the condensers C and C' respectively, but they may be connected serially in the resonant circuit as shown in Fig. 10, or they may be connected in shunt circuit to the coil L and condenser C' as shown in Fig. 11.

Though a coherer has been shown and described in the specification as the means of detecting the presence of oscillations in the receiving resonant circuits, under which circumstances it operates as a telegraphic relay to control a local battery circuit including an electric translating device, any other suitable electro-receptive device may be employed to receive the signal, as for example, a condenser telephone. When a condenser telephone is employed as a receiver, the receiving resonant circuit may be that illustrated in Fig. 12, in which C is the condenser telephone and also the capacity by which the circuit L C C' I, is attuned.

In Fig. 12 R' is a coil of very great impedence employed to prevent the passage of the electrical oscillations from the resonant circuit L C C' I into the battery circuit and the consequent disturbance of the resonance. The battery B should be of very high potential and it serves to maintain a permanent charge in the condenser telephone C. Such a charge greatly enhances the sensitiveness of the telephone and causes the attraction between its plates to vary more nearly in proper-

tion to the variations of electro-motive force at its terminals. As it is inconvenient to attain very high potentials by means of primary galvanic batteries, it will be found convenient in practice to employ either a Plante battery of very small capacity but of a large number of cells connected in series or else a condenser charged from time to time to a high potential.

In constructing the various parts of the apparatus shown and described in this specification there is great latitude as to the special forms that may be given them, but it must be remembered that when a circuit is to be tuned and it is desired to gain a high degree of resonance both electro-static and magnetic hysteresis must be carefully excluded from the resonant circuit. For this reason all iron should be excluded from the coils in the resonant circuits and solid dielectrics should not ordinarily be employed in the condensers. These injunctions apply to the construction of resonant circuits attuned to very high frequencies, but not with the same force to the construction of resonant circuits to be tuned to low frequencies. Another precaution to be taken in the construction of the apparatus included in the resonant circuits when very high frequency currents are employed is that conductors between which there exists a considerable potential difference during the operation of the apparatus shall be kept as far apart as practical, because of the excessive displacement currents which tend to flow in the case of high frequency currents. For this reason it will often be found to be convenient to build the coils in the form of flat spirals instead of long spirals of several layers as is the usual construction of coils.

14
94

In this specification I have spoken of elevated conductors, vertically elevated conductors, and vertical conductors. I wish to be understood as including in the term "elevated", conductors disposed at an angle to the earth's surface as distinguished from horizontal conductors, disposed parallel to the earth's surface. By the terms "vertically elevated" and "vertical", I refer to conductors whose disposition with regard to the earth's surface is mainly or wholly at a right angle or vertical thereto, which is the particular form of elevated conductor preferred by me for use in connection with my present improvement.

Having described my invention, I claim:

1. The method of developing simple harmonic electro-magnetic waves of a definite periodicity, which consists in producing forced simple harmonic electric vibrations of the same periodicity in an elevated conductor.

2. The method of absorbing the energy of simple harmonic electro-magnetic waves of one periodicity to the exclusion of the energy of electro-magnetic waves of different periodicity which consists in associating with an elevated conductor a resonant circuit or a group thereof attuned to the same period as that of the waves the energy of which is to be absorbed.

3. The method of distributing the energy of electro-magnetic waves which consists in independently developing forced simple harmonic electric vibrations of different periodicities in elevated conductors and conveying the several components of the resulting electro-magnetic waves, each selectively, to separate electric translating devices.

4. The method of distributing the energy of electro-mag-

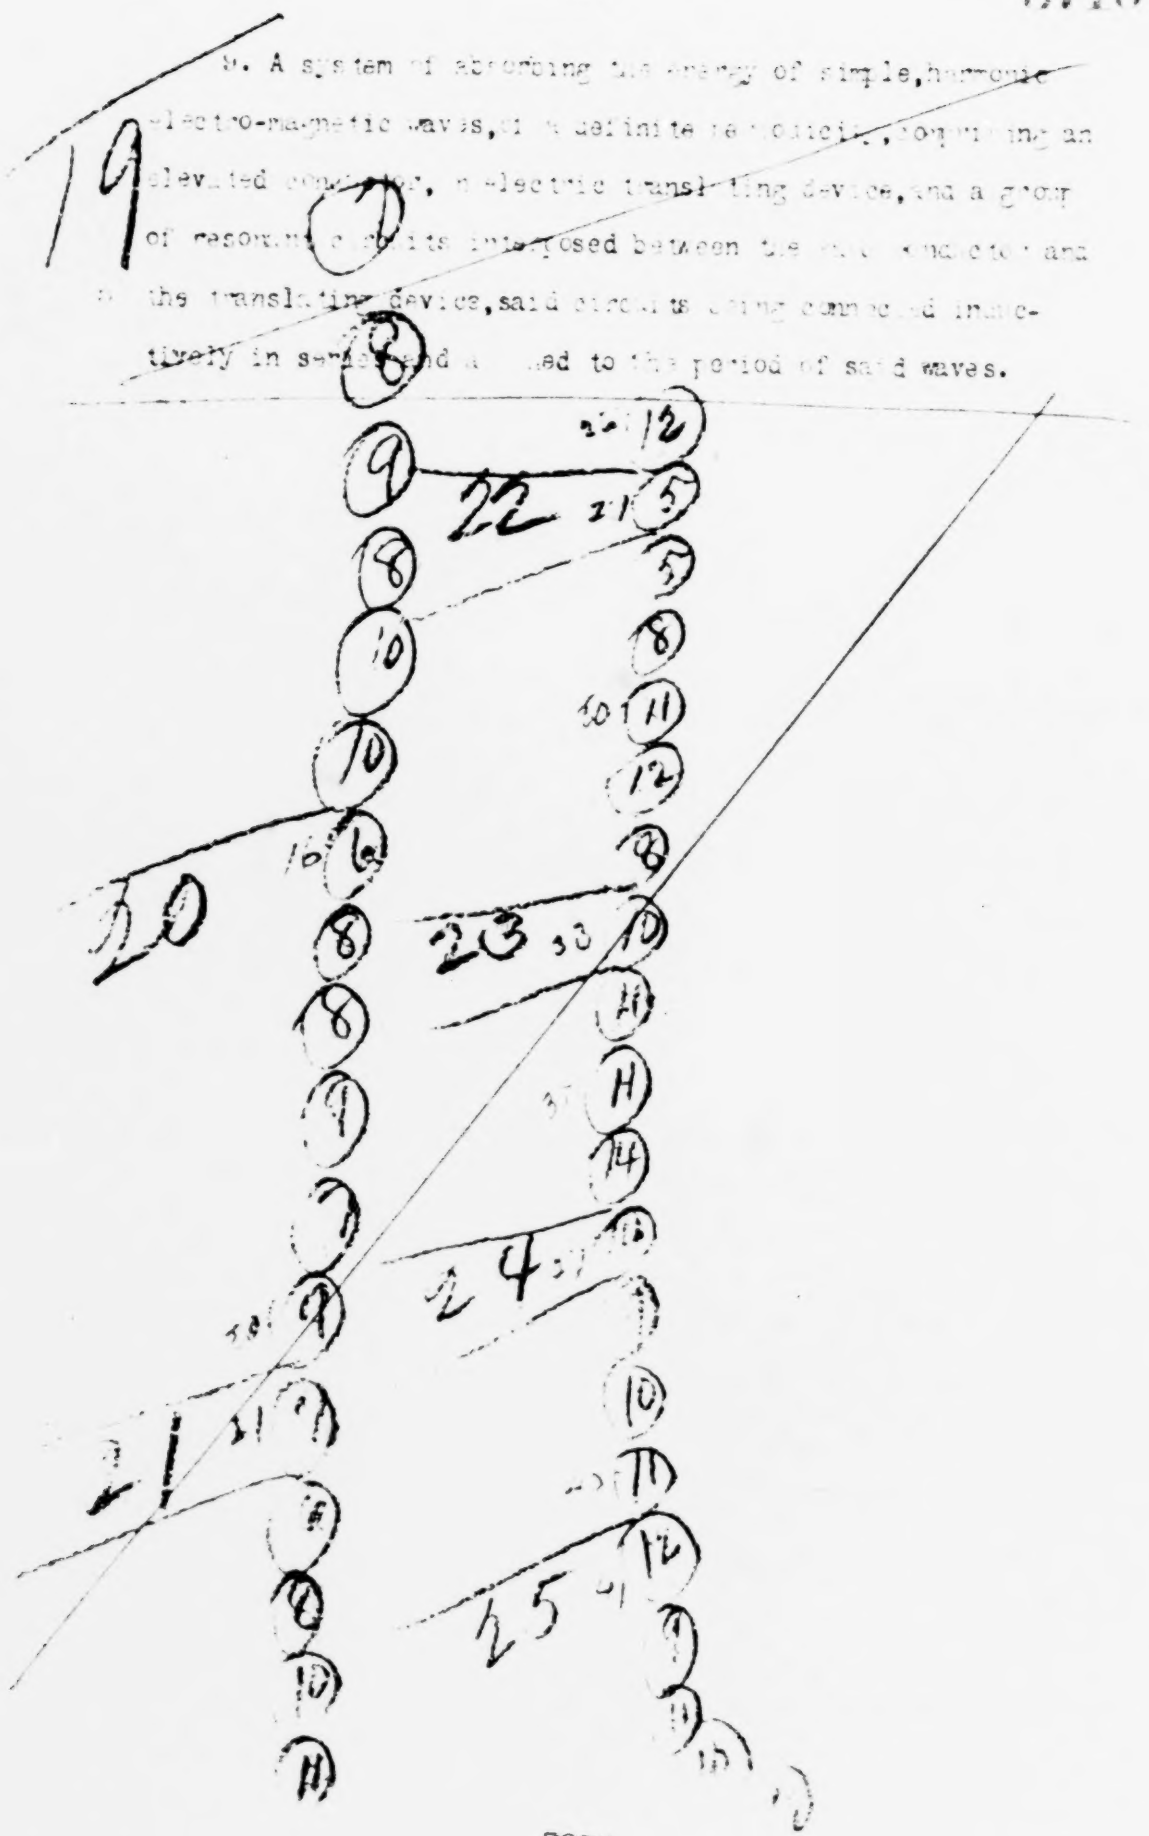
netic waves which consists in independently developing a number of forced simple harmonic electric vibrations of different periodicity, [illegible] electro-magnetic waves, each selective, [illegible] or group thereof attuned to [illegible] waves, the energy of which is to be absorbed [illegible].

6. A system of utilizing the energy of electro-magnetic waves, comprising an elevated conductor, means of independently developing therein forced, simple, harmonic electric vibrations of a definite periodicity, a resonant circuit or group of circuits, associated with a second elevated conductor attuned to the said definite periodicity, and an electric translating device [illegible].

7. A system for the absorption of energy of electro-magnetic waves, comprising an elevated conductor, means independently developing therein forced simple harmonic electric vibrations of different definite periodicities, and a number of resonant circuits or groups of circuits, each one elevated conductor attuned to one of said periodicities, and an electric translating device associated with each resonant circuit or group thereof.

8. A system for developing simple harmonic electro-magnetic waves of a definite periodicity, comprising an elevated conductor, a generator of vibratory electric currents, and a number of resonant circuits, connected inductively in series and interposed between the said conductor and the generator.

9. A system of absorbing the energy of simple, harmonic electro-magnetic waves, of a definite period, comprising an elevated conductor, a electric translating device, and a group of resonant circuits interposed between the conductor and the translating device, said circuits being connected inductively in series and adapted to the period of said waves.



In testimony [illegible] I have hereunto subscribed my hand this 6th day of February, 1900.

Application of John Stone Stone,

for Patent for Improvement in Method of and Apparatus for Selective Electric Signaling,

filed Feb 27, 1900, allowed ---

In reply to Office Letter of March 10, 1900.

21 State
~~31~~ WATER STREET, BOSTON, [illegible], 1901

To the Commissioner of Patents, Washington, D.C.

SIR:

Pursuant to the requirements of the Examiner, the present case is amended by cancelling claims 1, 2, 3, and 4, as the same form the subject matter of another application sworn to and filed; also by amending the title of the invention as set forth in the petition and at page 1, line 4 of the specification, by erasing the words "and apparatus for."

Also by erasing from the specification the paragraph beginning at line 11, page 15.

Amend Fig. 1 of the drawing by erasing the box F, impedance coil R', and the connections between the same and the resonant circuit I, C, C', I'. The portions of the specifications and drawings desired to be erased by the foregoing amendments are inadvertently inserted by inadvertence.

Respectfully,

Alex. P. Browne,

Filed Feb. 3, 1900, Ser. No. 4505, for Method of and Apparatus for Selective Electric Signaling.

C. H. Duell

Commissioner of Patents.

This application has been considered in connection with the amendment of Jan. 23, 1901.

It is thought that applicant intended to refer to figure 3 instead of figure 2 in line 18 of page 7 of his specification.

Claim 1 covers a method for developing simple harmonic electromagnetic waves of a definite periodicity by setting up simple harmonic electric vibrations of the same periodicity of an elevated conductor. The nature or disposition of the conductor in which such electric vibrations are set up in no way affect the method per se. The claim is accordingly rejected upon the patent to Pupin, 640,515, Jan. 2, 1900, Telegraphy, Multiplex.

Claim 2 is rejected upon the patent to Tesla, 627,650, June 27, 1899, Telegraphy, Circuits and Systems, particular reference

In every amendment the exact word or words to be stricken out or inserted in the application must be specified and the precise point indicated where the erasure or insertion is to be made. All such amendments must be on sheets of paper separate from other papers previously filed, and written on but one side of the paper.

In every application for a patent filed subsequent to December 31, 1897, responsive action must be made by the inventor within one year after the last official action or the case will become abandoned.

being had to figure 1.

Claims 3 and 4 are not understood for the reason that it is not clear whether one or several conductors are implied, that is, whether the independent frequencies are impressed upon one or different conductors. However this may be claims 3 and 4 are deemed to be met in the patent to Pupin, 640,316, cited above, and for the reasons stated in connection with claim 1. Attention is also called to the system found in the British patent to Lodge, 29,505 of 1897, of record.

Room No.61, Serial No.4906,

Application of John Stone Stone,

For Patent for Improvement in Method of and Apparatus for Selective Electric Signaling,

Filed February 8,1900,

In reply to Office letter of February 13,1901.

---

31 State street, Boston,

March 23,1901.

To the Commissioner of Patents,

Washington, D.C.

Sir,

Amend the title by striking out the words 'and Apparatus therefor.'

Amend the specification by striking out '2' in line 18 of page 1 and replacing it by '1'.

Amend claim 1 by inserting the words 'free or unguided' in line 13,page 20,after the word 'developing.'

Amend claim 2 by inserting the words 'free or unguided' in line 17,page 20,after the words 'energy of' and by inserting the words 'free or unguided' in line 18,page 20,after the words 'energy of.'

Amend claim 3 by inserting the words 'free or unguided' at line 23,page 20,after the words 'energy of.' Also by erasing the word 'conductors' at line 24,same page,and substituting the word 'conductor,'also in the same line by inserting the word 'an' after the word 'in',and by inserting at line 27,

same page, the word "a" after the word "to."

Amend claim 4 by inserting the words "free or unguided" in line 24, page 20, after the words "energy of"; also by erasing the word "conductors" and substituting the word "conductor" at line 3, page 21. Also in the same line by inserting the word "an" after the word "in."

Add two claims 5 and 6 respectively, as follows:

"5. The method of distributing the energy of free or unguided electro-magnetic waves which consists in developing forced simple harmonic electric vibrations of different periodicities, each in a different elevated conductor, and ~~conducting~~ the several energies of the resulting electro-magnetic waves, each selectively, to a separate electric translating device.

"6. The method of distributing the energy of free or unguided electro-magnetic waves which consists in developing a number of forced simple harmonic electric vibrations of different frequencies, each in a different elevated conductor, and ~~conducting~~ the several energies of the resulting electro-magnetic waves, each selectively, to a separate resonant circuit, or group thereof, attuned to the same period as that of the waves, the energy of which is to be absorbed therein."

Argument upon the pertinency of the [illegible] in reference is made for convenience in a separate paper filed herewith.

Respectfully,

Alex P Browne

4505-3

In the United States Patent Office.

Room No.81, Serial No.4505,

Application of John Stone Stone,

For Patent for Improvement in Method of and Apparatus for Selective Electric Signaling,

Filed February 8,1900,

In reply to Office letter of February 12,1901.

---

31 State street, Boston,

March 23,1901.

To the Commissioner of Patents,

Washington, D.C.

Sir,

A r g u m e n t .

Applicant does not understand that the Examiner in rejecting claim 1 of the application upon Pupin's patent No. 640,918 contends that there is no novelty in using in a system of space telegraphy, free or unguided simple harmonic electro-magnetic waves which are developed by producing forced simple harmonic electric vibrations in elevated conductors. He understands that claim 1 is rejected because it is by the Examiner construed to be in terms broad enough to cover a method of developing guided simple harmonic electro-magnetic waves which are developed by producing forced simple harmonic waves in an elevated horizontal conductor or main line, since this is the nature of the disclosure contained in the patent to Pupin referred to by the Examiner.

Such a construction of claim 1 is deemed by the applicant to be too broad since the claim must be construed with refer-

ence to the specification of which it forms a part, in which the meaning attached by the applicant to the term 'elevated conductor' is explicitly stated (see lines 1 to 11 inclusive, p. 20 of the application.) The paragraph in the specification above referred to forbids the interpretation of the term 'elevated conductor' in claim 1 as meaning an elevated horizontal conductor in a straight line, and it also by virtue of the accompanying lines covering the phenomena involved, precludes the interpretation of the term 'simple harmonic electro-magnetic waves' in the claim as including guided simple harmonic electro-magnetic waves.

Electro-magnetic waves emanating from an elevated conductor, if the term elevated conductor be used in the sense in which the applicant has applied it in his specification, are not intended except in so far as the earth or water over which they travel may be considered to exert a guiding influence.

Applicant's attorney contends that the claim in its original form is not susceptible of a construction which would make it read on anything in the art. The invention as claimed is [illegible] and the claim is not indefinite.

Nevertheless the application for the purpose of eliminating the question will be amended in the manner set forth above, and the claim will be rejected as thus amended.

Respectfully,

Geo. P. Brown
Asst. Examiner

91.

DEPARTMENT OF THE INTERIOR

UNITED STATES PATENT OFFICE,

WASHINGTON, D. C. April 10, 1901.

John Stone Stone,

Care, Alex. P. Browne,

31 State St.,

Boston, Mass.

Please find below communication from the **EXAMINER** *in charge of your application.*

Filed Feb. 8, 1900. Ser. No. 4,505. For Method of and Apparatus for Selective Electric Signaling.

Fig. 1 of the drawings will be changed as requested by the applicant, on the filing of proper prints.

Claim 1 is again rejected upon the patent to Lupin of record. So far as the method of developing the waves is concerned, it is immaterial whether they be guided or free and unguided, and the fact that they are to be used in the wireless system is immaterial. Attention is called to the statement of invention in the Lupin patent.

Claim 2 is again rejected upon the patent to Marconi 697,040 of record. Claims 3 and 4 are each rejected upon Swiss patent to Braun, 18,377, taken in view of Lupin of record.

The application of the Lupin method of developing simple or onic waves as applied to the Braun system is [illegible].

Claims 3 and 4 are drawn to separate species of inventions as described in claims 5 and 6, and the drawings does not appear a sufficient showing of a proper basis for any of the claims 3, 4, 5 and 6.

Said claims 5 and 6 amount simply to aggregations. There is no patentable cooperation between independent telegraphic systems which operate with a definite periodicity for its waves.

Application of John Stone Stone,

For Patent for Improvement in ~~Apparatus for~~ Selective Electric Signaling.

Filed ~~January 23, 1902.~~ Feb 8 1902

In reply to office letter of April 16,1901.

31 State Street, Boston.

April 8,1902.

To the Commissioner of Patents,

Washington,D.C.

Sir:

The case is amended as follows:

Insert in the specification, after the paragraph ending page 4, line 22:

"Thus the frequency impressed upon the elevated conductor may or may not be the same as the natural period or fundamental of such conductor, but as will be hereinafter explained, an elevated conductor that is aperiodic may be employed, and is well adapted for use when the apparatus is to be used successively for different frequencies, and such aperiodic elevated conductor is likewise a preferred form of elevated conductor when two or more frequencies are to be simultaneously impressed upon or received by a single elevated conductor.

"But forced simple harmonic electric vibrations of different periodicities may each be separately impressed upon a different elevated conductor, and the several energies of the resulting electromagnetic waves may be selectively conveyed each to a separate [illegible]

After the [illegible] line 4 insert:

"When, however, the elevated conductor is aperiodic it is [illegible] receive or transmit [illegible] frequencies, and accordingly

a single aperiodic elevated conductor may be associated with a plurality of local circuits, each attuned to a different frequency by the means now well known in the art of multiple telegraphy by wire conductors.

"Where a single elevated conductor is to be made a source of a plurality of signal waves of different frequencies, and when ... desirable, these signal waves are to be simultaneously developed, it is ... necessary that the trains of waves of different frequencies ... upon the elevated conductor shall be ... it is necessary that the electric vibrations ... upon the elevated conductor shall not ... simultaneously impinging vibrations of ... frequencies. The manner of developing the ... in this ... to the receiving ... different frequencies ... simultaneously impressed upon the elevated conductor ... preferred form of apparatus for transmitting the apparatus will never ... that is necessary, or fully described in order to add to it, or complement of the specification."

Page 10, line 26, erase the word "transmitting" and substitute the word "translating."

Page 11, line 20, insert:

"C and C' are diagrams illustrative of forms of transmitting ... capable of developing signal waves of two different ...

... and R' are diagrams illustrative of forms of receiving stations capable of receiving selectively signal waves of two different frequencies."

Page 12, line 2, erase the word "and"; introduce after "C''" the words "and C'''".

Page 12, line 3, erase all after "K" and substitute "and K are ... coherers."

Page 12,line 6,insert [illegible] for "battery"

and P and S are Plants batteries

Page 12,line 6,erase "is" and [illegible]

"key" and substitute "keys"

Page 12,line 7,erase "a" and [illegible]

erase "relay" and substitute "relays"

Page 12,line 8,erase "device" and substitute "parts"

Page 12,line 9,erase "is an" and [illegible]

erase "interrupter" and substitute "interrupters"

Page 12,line 10,[illegible]

erase "cap" and substitute "caps"

At the end of page 12 insert

"The terminal wire may be made of [illegible] to be highly resistant to [illegible] but the [illegible] resistance increased [illegible] of the wire. The construction of such a radial wire is [illegible] other applications of wire [illegible]"

The following amendment and [illegible] added by amendment are presented in reference to [illegible] contained in the Office letter of April 16, 1928, that there is not sufficient showing in the drawings to form a proper basis for the claims 3,4, and 5.

The amendment applicant deems to meet the requirements of the Office so far as they relate to claims 3 and 4. As regards the bearing of the Office action in connection with claims 5 and 8, applicant respectfully submits that the drawings marked Figs. 1 to 8, inclusive, are sufficient as for these claims, also if he were to show in his drawings a [illegible] comprising [illegible] transmitting stations and more than one receiving station, associated with a separate circuited [illegible], it would result merely in reduplicating Figs. 1, 2, 7 and 8. This is not [illegible] that the several transmitting stations would be identical in construction

and the various receiving stations identical in construction, but because the difference in frequency employed at these stations is not susceptible of being readily shown in the diagrams, or what amounts to the same thing the differences in the inductances of the coils and the capacities of the condensers are not readily [illegible] diagrams of the type used.

[illegible] cannot agree with the Examiner that there is no [illegible] feature in the organization covered by claims 5 and 6. It [illegible] sufficient to note that ever since the art of wireless [illegible] been practised, the great need for commercial purposes [illegible] system as is sought to be covered in claims 5 and 6 has been fully recognised. Ever since the art of wireless or space telegraphy has existed, the problem, a solution of which is claimed in claims 5 and 6, has been one of vital importance and the principal commercial value of wireless telegraphy has depended upon its practical solution. Applicant contends that he who solves this problem in a thoroughly practical manner has added more to the commercial value of wireless telegraphy than any one else and is entitled to the protection sought to be secured in claims 5 and 6.

Regarding the amendment in question, applicant farther submits that owing to the fact that his transmitting and receiving stations illustrated in Figs. 5, 6, 7 and 8, are inherently selective by virtue of the auxilliary coils L, L', L'', etc., and that a plurality of such stations can therefore be associated in any desired way with a common vertical wire to form the system sought to be covered by claims 5 and 6, he did not at first consider it necessary to include drawings and a detail description of the organization sought to be covered in these claims. Applicant, however, now concurs with the Examiner, and feels that the present amendment to the specification and the added sheets of drawings increase the completeness with which the invention as a whole is set forth.

The amendment which has been referred to above is as follows:

Page 17, after line 24, insert:

"The apparatus shown in Figs. 13,14,15, and 16 illustrate methods of associating the apparatus hereinbefore described, and illustrated in Figs.5,6,7, and 8, when two or more stations are to be associated with a common elevated conductor. The operation of each individual station is the same as that already described in connection with Figs.5,6,7, and 8. For the sake of clearness only two stations are shown associated with the common elevated conductor V in the drawings, but it is obvious that any desired number of stations may be associated with a common elevated conductor in the same manner.

"An inspection of the drawings will show that Figs.13 and 14 illustrate two transmitting stations of the type shown in Fig.7 associated with a common elevated conductor, whereas Figs.14 and 15 illustrate two receiving stations of the type shown in Fig.8 associated with a common elevated conductor.

"When a plurality of stations are associated with a common elevated conductor, each of the stations is characterized by being tuned to a different frequency from that of any of the other stations so associated. In Figs.13,14,15, and 16, it will be observed that the two different stations associated with a common elevated conductor have therein been differentiated by attaching a subscript to the letters of reference in the case of one of the stations and not to the letters of reference of the other station.

"The operation of each of the transmitting stations in Figs. 13 and 16 is identical with that of the transmitting station illustrated in Fig.7, and the operation of each of the receiving stations shown in Figs.14 and 17 is identical with the operation of the receiving station illustrated in Fig.8.

"To illustrate.- The step up transformer or spark coil M''' in Figs.13 and 16, is equipped with an interrupter p and condenser C''', and the current is supplied by the battery B. When the key is depressed, a high potential is developed in the secondary of M''' As the potential difference at the terminals of the secondary of

rises, the condenser C'' is charged till the resulting potential difference at a is sufficient to break down the spark gap g. When this occurs, the condenser C'' discharges through the spark gap, the primary of M', and the inductance coil L''. This circuit is attuned to a given high frequency and the oscillatory current which results is therefore of that frequency. This current induces a similar current in the interposed resonant circuit L', M', C', M attuned to the same frequency, which current in turn induces a current of corresponding frequency in the conductor V. The branch L M C is attuned to the given high frequency of the oscillation developed in the circuits L'' g C'' M' and L' M' C' M while the branch L C M is attuned to the frequency of the oscillations similarly developed in the circuits L'' g C'' M' and L' M' C' M. Since these two frequencies are different as hereinbefore specified, the energy of the oscillations developed in the one branch will not be materially absorbed in the other. In this way two sets of forced oscillations of different frequencies may be developed in the elevated conductor V without mutual interference.

Passing now to the operation of the receiving stations shown in Figs. 14 and 16, it may be remarked that since the operation of each of these stations is identical with the operation of the receiving station shown in Fig. 8, ~~it only remains to show that~~ the energy of the waves of one particular frequency will be absorbed by ~~communicated only to~~ one of the receiving stations and ~~that~~ the energy of the waves of another particular frequency will be absorbed by ~~communicated only to~~ the other receiving station.

In both Fig. 14 and Fig. 16 the branch circuits L M C and L M C are attuned each respectively to the same particular frequencies as the circuits M L' M' C' M' L'' C'' P and M L' M' C' M' L'' C'' P. When therefore simple harmonic waves of one of these particular frequencies impinge upon the vertical wire V, the energy of these waves is received in that particular branch circuit which is attuned to the frequency of the waves and is practically excluded from the other branch. The energy so received is communicated to the resonant circuits associated with this branch and affects the

receiving translating devices in the usual manner. This selective reception of the energy of waves of a particular frequency is independent of the number of waves of different frequencies which may be simultaneously present.

"It is to be here noted that the above described methods of simultaneously transmitting and receiving space telegraph messages by a common elevated conductor are the preferred methods, but that not discussed as the any way of associating a plurality of the stations shown in Figs. 5,6,7, and 8 with a vertical conductor will result in a system for simultaneously transmitting and receiving space telegraph signals owing to the fact that these stations are, themselves inherently selective and are capable of causing the independent development of vibrations of different frequencies in the elevated conductor and of selectively absorbing the energy of waves of different frequencies, even without employing the tuned branch circuits C - M and G - M." A30

The following amendment is made as the result of a recent interview with the Examiner in charge. Up to the time of that interview applicant had considered it sufficient to point out in his specification 1st, the great necessity of avoiding the effects of magnetic and electro-static hysteresis in the tuned circuits of his invention, and to specify that the coils should be constructed without iron cores and that solid dielectrics should not be employed in the condensers; 3d, to indicate that the usual forms of coils are not adapted for use in these tuned circuits for the reason of the excessive displacement-currents which tend to flow between conductors charged to a considerable difference of potential, and 4th, to suggest a form of coil in which this effect is less pronounced than in the usual form of coil. Applicant now concurs with the Examiner and feels that the following amendment adds to the completeness of the specification, since it is not necessary to indefinitely diminish the displacement currents in the coil, but suffices to reduce them to the point at which the potential energy

(3230)

of these displacement currents is small compared to the kinetic energy of the conduction current in the coil for the particular frequency of current with which the coil is to be used.

Insert after page 10 of the specification the following:

"Flat spirals with the turns well separated in order to minimize the displacement currents between the turns are, however, by no means the only form of coils adapted to be used in conjunction with air condensers for the purpose of tuning circuits to high frequencies, and may often be neither the best nor most convenient form of coil to employ. Therefore in defining the character of the coils to be employed for this purpose it will be advantageous to first give the general theoretical considerations which lead to a special construction of the coils and to then give a practical guide to the manner of designing the coils for any particular frequency or range of frequencies.

"A coil or solenoid as usually constructed consists of many turns of cotton or silk insulated wire wound on an insulating core such as a glass or ebonite tube or a wooden spool, the consecutive turns being separated only by the thin insulating coating [illegible] solenoids moreover are in general wound with several layers of turns, the layers also being separated from each other only by the insulating coatings of the wires. Such solenoids are well adapted to be used in conjunction with condensers having solid dielectrics for the purpose of tuning circuits to low frequencies, but neither such coils nor such condensers are available for the purpose of tuning circuits to such high frequencies as are contemplated with the present invention. In the case of high frequencies the energy absorbed in the solid dielectric of the condenser, due to dielectric hysteresis, is excessive, and the displacement currents between the adjacent turns and layers of the coil mask and neutralize the inductance of the coil. Moreover the solid dielectric forming the core of such coils exerts a deleterious effect which in some instances is probably partially due to its possessing a small degree of conductivity, but which must in most instances be ascribed to the high specific inductive capacity of

the material and to its dielectric hysteresis.

"In order to tune a circuit to a predetermined high frequency so that it shall show well defined selectivity for that frequency to the exclusion of other frequencies, even to the exclusion of frequencies differing but slightly from the predetermined frequency, it is necessary not only that the condenser shall be free from dielectric hysteresis, but that the coil shall be so constructed as to behave for that frequency practically like a conductor having a fixed resistance and a fixed inductance, but devoid of capacity. Coils constructed in the usual way do not behave for high frequencies as if they had a fixed resistance and inductance and no capacity, but partake more of the character of conductors having distributed resistance, inductance and capacity. In fact they may in some instances behave with high frequencies more like condensers than like conductors having fixed resistance and inductance and no capacity. Since a coil constructed in the usual way behaves for high frequencies as a conductor having distributed resistance, inductance and capacity, it follows that such a coil will show for high frequencies the same quasi-resonance as is observed with low frequencies in long aerial lines and cables, i.e., that it will per se, and without the intermediary of a condenser show a slight degree of selectivity for some particular frequency and for certain multiples of that frequency, just as a stretched string which has distributed inertia and elasticity, will respond to the particular tone called its fundamental, and to all other tones whose periods are aliquot parts of the periods of that fundamental. But it is not with such quasi-resonance that the present invention is carried into effect, and I wish it understood that I hereby disclaim any system employing distributed inductance and capacity as a means for tuning the resonant circuits described in this specification.

A general criterion which determines the utility of a coil for tuning a circuit to a particular high frequency is that the

potential energy of the displacement currents in the coil shall be small compared to the kinetic energy of the conduction current flowing through the coil when the coil is traversed by a current of that frequency.

I have found that for a single layer coil the following procedure is sufficient for practical purposes. Determine the inductance of the coil by formulae to be found in the text books and treatises on electricity and magnetism. This will enable the kinetic energy of the coil to be determined for any particular current and will also permit of the determination of what would be the potential gradient along the coil for the current of the frequency to be employed if the coil were devoid of distributed electrostatic capacity. Next calculate the electrostatic capacity between an end turn and each of the remaining turns of the coil. These capacities together with the potential gradient found will enable the potential energy to be determined, and if the ratio of the potential energy to the kinetic energy so found be negligible compared to unity, the coil will practically satisfy the requirements hereinbefore mentioned. If the coil does not meet the requirements the design should be so changed as to increase the separation between the turns, or the size of the wire should be diminished or the dimensions of the coil so otherwise altered as to decrease the distributed capacity without proportionately diminishing the inductance. The calculations may be greatly abbreviated and the liability to error greatly reduced if the results of the computations be plotted in curves.

"Regarding the effect of a dielectric core in a coil to be used for tuning a circuit to a high frequency, it is sufficient to state that the preferred form of support for such a coil is any skeleton frame which will hold the turns of wire in place without exposing much surface of contact to the wires and affording a minimum of opportunity for the development of displacement currents within itself."

4505-45

Claims:

Amend claim 3 by striking out the word conveying",line four thereof,and substituting therefor the word "receiving"; by adding the words "at a distance," after the word "waves" in the fifth line thereof,and by striking out the word "to" in line five and substituting the word "in."

Amend claim 4 by striking out the word "carrying",line four thereof and substituting the word "receiving";by adding the words "at a distance," after the word "waves",in the fifth line thereof; by striking out the word "to" in line six thereof and substituting the word "in" therefor.

Amend claim 5 by striking out the word "conveying" in line four thereof and substituting the word "receiving"; by adding the words "at a distance," after the word "waves" in the fifth line thereof; by striking out the word "to",line six thereof,and substituting the word "in."

Amend claim 6 by striking out the word "carrying",line five thereof,and substituting the word "receiving" therefor; by adding the words "at a distance," after the word "waves" in the sixth line thereof; by striking out the word "to",line six thereof,and substituting the word "in" therefor.

Add the following claims:

"7. The method of tuning a circuit to a given high frequency, which consists in balancing the reactance of an air condenser by the reactance of a coil,the amplitude of whose potential energy is small compared to the amplitude of its kinetic energy when it is supporting a current of said given high frequency.

"8. The method of constructing a coil to be used in a circuit to be tuned to a given high frequency, which consists in so proportioning the coil that the amplitude of its potential energy shall be small compared to the amplitude of its kinetic energy when supporting a current of said given high frequency.

4505-46

"9. The method of developing free or unguided simple harmonic electro-magnetic signal waves, which consists in discharging a condenser through a closed circuit having inductance adapted to produce under such conditions simple harmonic vibrations, and impressing the electrical vibrations so produced upon an open circuit or elevated conductor substantially as described.

"10. The method of developing free or unguided simple harmonic electro-magnetic signal waves which consists in discharging a condenser through a closed circuit having inductance adapted to produce under such conditions simple harmonic vibrations, impressing these vibrations on a resonant circuit or group thereof attuned to the frequency of these vibrations, and impressing the resulting electrical vibrations upon an open circuit or elevated conductor.

"11. The method of selectively receiving the energy of simple harmonic electro-magnetic signal waves of different frequencies, which consists in receiving the same in an elevated conductor and translating or conveying the several energies of the resulting electrical oscillations each to a separate resonant circuit, associated with said elevated conductor and attuned to the frequency of the electro-magnetic waves, the energy of which it is to receive.

"12. The method of selectively receiving the energy of simple harmonic electro-magnetic signal waves of different frequencies which consists in receiving the same in an elevated conductor and translating or conveying the several energies of the resulting electrical oscillations, each to a separate group of resonant circuits, associated with said elevated conductor and attuned to the frequency of the electro-magnetic waves the energy of which it is to receive.

"13. The method of selectively receiving the energy of simple harmonic electro-magnetic signal waves of different frequencies which consists in receiving the same in a plurality of elevated conductors, thereby developing in each elevated conductor electrical oscillations corresponding in frequency to the electro-magnet-

ic waves received by it and in translating o conveying from each elevated conductor to an associated resonant circuit the energy of the particular electrical oscillations to the frequency of which said associated circuit is attuned.

"14. The method of selectively receiving the energy of simple harmonic electro-magnetic signal waves of different frequencies which consists in receiving the same in a plurality of elevated conductors, thereby developing in each elevated conductor electrical oscillations corresponding in frequency to the electro-magnetic waves received by it and in translating or conveying from each elevated conductor to a group of resonant circuits associated therewith the energy of the particular electrical oscillations to the frequency of which said group of associated resonant circuits is attuned."

IN THE UNITED STATES PATENT OFFICE.

Room No.31. Serial No.45055.

Application of John Stone Stone,

For Patent for Improvement in ~~Apparatus for~~ Selective Electric Signaling.

Filed ~~June 23,1901~~ Feb 5 1902,

In reply to Office letter of April 10,1901.

---

51 State street, Boston,

April 8,1901.

To the Commissioner of Patents,

Washington,D.C.

Sir:

In reply to references cited by the Patent Office.

Claim 1 having been rejected upon the patent to Pupin, No 640,515 of January 2,1900, applicant respectfully submits that the specification of the Pupin patent was written in 1895 as appears on its face and that it is only in the light of the subsequent advance of the art and of the present invention that anything contained in the Pupin patent could possibly have been construed to suggest a system for developing free or unguided forced simple harmonic signal waves emanating from an elevated conductor used as a radiator, and passing out from it to great distances through the surrounding atmosphere in the form of radient energy. The object of the Pupin invention is in fact to develop practically independently in a single line conductor, two currents of different frequencies in order that these two currents may be used for duplex telegraphy by being selectively received in separated branch circuits at the receiving end of the line, each branch circuit being tuned to the frequency of one of said alternating currents

If, however, the apparatus described in Pupin's patent for

developing currents of different frequencies in a line conductor could be employed to develop the electrical vibrations in the elevated conductors or radiators of applicant's present invention, then it might be alleged that Pupin's invention had a double use to which he was entitled even though he did not apprehend it at the time of filing his application, or did not consider it worth claiming or even mentioning in his specification. But the apparatus of the Pupin patent is not, in the present state of the art, capable of being employed for the development of the electro-magnetic signal waves described by applicant in his specification. This is for the reason that the lengths of waves generated by the means described in the Pupin patent are of the order of 10^3 as compared with those which in the present state of the art are available for the purposes of the present invention. In the present state of the art such frequencies as are capable of being developed by the only apparatus described or suggested in the Pupin patent, if impressed upon an elevated conductor of practicable dimensions would produce no appreciable radiation of energy, i.e., the resulting electrical vibrations in the elevated conductor would give rise to practically no free or unguided electro-magnetic waves. There would be but a negligible amount of the energy which would emanate from the oscillator never to return to it. Practically all the energy would be confined to the neighborhood of the oscillator and would flow out and back with each oscillation.

Now if in the immediate future it be shown that by the use of a specially constructed elevated conductor, the apparatus described or implied in the Pupin patent becomes available as a practical means of developing electro-magnetic waves of practical utility in the art of wireless telegraphy, then the method of so specially constructing the elevated conductor may, and in the judgment of the applicant will, itself involve invention, and the specially constructed elevated conductor when used with the apparatus in the Pupin patent in like manner constitute a patentable invention.

Claim 2 having been rejected upon the patent to Marconi No. 627,650 of June 27,1899,applicant respectfully submits that in the first place the object of the Marconi patent was not to selectively receive the energy of electro-magnetic waves of one frequency to the exclusion of the energy of waves of other frequencies.

His object was to overcome certain inherent difficulties in the system which he had previously been employing. In that earlier system the elevated conductor (which in the patent cited as a reference he styles a capacity) was connected to the earth through the coherer,and the static charges,owing to atmospheric electricity,which accumulated upon the elevated conductor discharging through the coherer seriously interfered with the proper operation of the system. In order to overcome this difficulty,Mr. Marconi placed the coherer in a branch or local circuit,not conductively connected with the elevated conductor,and grounded the elevated conductor through a coil. The static charges accumulated by the elevated conductor were thereby permitted to readily pass to earth without interfering with the operation of the coherer.

Mr.Marconi must have been perfectly aware,at the time of filing of his application for the patent now cited as a reference in this case,of the great practical importance of securing a selective system of space telegraphy,and yet we find in this patent no reference to such a system,and it is only by implication and in the light of applicant's specification that a passage in the Marconi patent can be construed to indicate that Marconi had any intention of disclosing in this patent the invention sought to be covered in claim 2 of the present application. But as will hereinafter be fully and clearly shown,the above referred to passage in Marconi's patent has a well defined meaning of its own and any other interpretation of it is wholly unwarranted. Mr.Marconi did not consider the invention of the patent cited as a solution of the problem of selectively receiving the energy of simple harmonic electro-magnetic signal waves of one frequency to the exclusion of those of other frequencies,and therefore did not in this patent

claim to [illegible] important invention. If he had considered his invention a solution of so important a problem,he would not have published the solution in his patent without claiming it,and would not have satisfied himself with the claims he did make.

It may be contended that though Marconi did not at the time of filing his application,know that his apparatus could,or intend that it should,be used for selectively receiving the energy of simple harmonic electro-magnetic waves of one frequency to the exclusion of those of other frequencies,yet the apparatus of his patent is capable of such use,and that therefore his patent constituted a publication of such a system of selectively receiving the energy of simple harmonic waves of one frequency to the exclusion of waves of other frequencies.

The answer to such a contention is that the Marconi patent does not disclose a system which could operate to selectively receive the energy of waves of one frequency to the exclusion of the energy of those of other frequencies. The instructions contained in this patent are sufficiently explicit to forbid such an hypothesis.

These instructions as to the manner of constructing the coil make the apparatus incapable of such use,and furthermore we must note in the specification the absence of any specific instruction as to the proper conditions for the tuning of circuits to such high frequencies as are involved in the present invention. The Marconi specification specifically instructs us,both in text and drawing,to construct the induction coil of fine insulated wire,in very much the same manner as solenoids are usually constructed in practice,with the turns close together; and particular stress is laid upon the importance of having the primary and secondary quite close to each other. This practically instructs us to wind the secondary immediately upon the primary. Owing to the displacement currents which take place in the case of high frequencies,where precautions are not taken to prevent them, such a coil will behave more like a condenser than a [illegible]. It would be absolutely

impossible to balance the reactance of such a coil by the reactance of a condenser for high frequencies.

Furthermore the entire absence from the Marconi specification of any instructions concerning the necessity of avoiding the effects of electrostatic and magnetic hysteresis,and the effects of displacement currents in the apparatus constituting the branch circuit,which includes the coherer,would of itself preclude the Marconi patent from being properly considered as in any way a disclosure of the invention sought to be claimed by applicant.

The passage in the Marconi specification before mentioned,in which there might seem to be some hint of a selective system,is: "It is desirable"(note,not essential) "that the induction coil should be in tune or syntony with the electrical oscillations transmitted,the most appropriate number of turns and the most appropriate thickness of wire varying with the length of wave of the oscillations transmitted."

The true meaning of this passage is that the organization described in the patent is capable of receiving the waves,whatever be their length within practical limits,but that the apparatus will be more efficient for this purpose if the coil is tuned to the frequency of the waves to be received. It has long been known that a circuit may be rendered sensitive to oscillations of a certain limited extent of frequency by the proper adjustment of the coil for certain frequencies both for the fundamental and for the harmonics or overtones of the fundamental as compared with other frequencies. The analogy in sound to this is familiar,namely the stretched string vibrating normally in its fundamental and in notes corresponding to aliquot parts of the period of the fundamental.

In the operation of the organization described in the Marconi patent,it is clear that owing to the manner in which the coherer coil is constructed,it does not operate as a simple inductance,but that electrostatic capacity in the convolutions in the coil and the displacement current through the coherer,but with more or less

combination of a conden[illegible]oil by which the [illegible]
lations in the elevated [illegible]ted through the [illegible]
circuit in passing to the [illegible]tion.

Claims 3 and 4 each [illegible]. the Swiss patent to
Braun,No.18,577 of June [illegible]view of the United [illegible]
patent to Pupin No.[illegible],[illegible]900,and it is implied in
the Office action of [illegible] this action is taken be-
cause the applic[illegible]ethod of developing simple
harmonic waves [illegible]Braun system is unpatentable.
Applicant resp[illegible]s that he has not seen the Braun
Swiss patent cit[illegible]t he has had access to and examined
copy of the Swi[illegible]tent to Braun No.1862 of 1899,which is
later date [illegible]ion he believes to be for the same invention
as the Swiss patent cited. Applicant fails to see what bearing
either of these patents can have upon that part of either claim
or claim 4 which relates to the selective reception [illegible]
of waves of different frequencies,each in a separate receiving
station,since both the Pupin and Braun patents are restricted to
paratus to be used at transmitting stations.

Applicant finds that the object of the Braun invention is to
obtain free or unguided electro-magnetic signal waves of greater
length than those given by a Hertz oscillator,and this he seeks
to accomplish in order that the signals may less easily be ob-
structed in their passage from the transmitting to the receiving
station by intervening obstacles such as houses,hills,etc.

For this purpose it was wholly unnecessary that Braun's sig-
nal waves should be simple harmonic in character,and his specifi-
cation makes no provision that they shall be simple harmonic
in character.

Applicant has already argued in his letter to the Office of
March 23,1901 that the electric vibrations in the apparatus dis-
closed by Braun are the natural vibrations of a system of at least
two degrees of freedom and are in general therefore not of a sim-
ple harmonic character. This point does not seem to be contended
by the Examiner. In view of the fact that the Examiner has again
rejected [illegible] upon the patent to Braun in view of the patent to

Applicant now further points out that there is not even an allusion in the Braun disclosure to the necessity of guarding against the effects of electrostatic and magnetic hysteresis in the associated circuits, and since there is no hint in Braun's disclosure of the importance of so constructing the coils as to avoid the effects of displacement currents, one seeking to practice the invention of the Braun patent would employ the usual forms of coil and condenser. Such apparatus, though it might operate to accomplish the results sought by Braun, would be wholly unsuited to perform the functions of the apparatus of the present application. The apparatus of the Braun patent is simply a combination of the Tesla apparatus for producing high frequency currents with the elevated conductor as radiator of a wireless telegraph station to form a wireless telegraph transmitting station sending out waves if greater length than those theretofore employed in wireless telegraph stations of the elevated conductor type.

Applicant contends that in order to properly tune the circuits described in his application, either the auxilliary coils L,L',L'',etc., must be included in those circuits, or the inductive coils M,M',M'',etc., must be so specially constructed as to furnish the auxilliary inductance which these coils impart to the circuit. Moreover the most strict attention must be given to the exclusion of electrostatic and magnetic hysteresis in these circuits.

DEPARTMENT OF THE INTERIOR.

UNITED STATES PATENT OFFICE,

WASHINGTON, D. C. May 13, 1902.

4532

John Stone Stone,

Care, Watson & Watson,

Washington, D.C.

RECEIVED MAY 13 1902 FILED

Paper filed being a communication from the EXAMINER in charge of your application,

Ser. No. 4505, for Method of Selective Electric Signalling, filed Feb. 8, 1900,

F. I. Allen

Commissioner of Patents.

This action is in response to applicant's communication filed Apl. 11 and 12, 1902.

It is evident that the original specification in view of the state of the art would justify the addition of views showing two local circuits tuned to different frequencies inductively connected to a single aperiodic sending or receiving conductor, but it is obvious that the present showing of specifically novel modifications of parallel and series tuned conductively connected branch circuits is specifically new matter for which there was no adequate foundation in the case as originally filed.

Additional illustration should therefore be limited to the unobjectionable form and the present new illustration presented, if at all, in a new application. It seems evident that many specific claims could be drawn to the apparatus now shown that would be clearly patentable over the disclosure in the case as originally presented.

The grounded conductor VR should therefore be shown as a single straight wire broken only by the secondary windings I_2, the induction coils I, I_1 and condensers C, C' being omitted therefrom.

If it should appear that the presence of the two transformer secondaries in the sending and receiving conductors give them a concurrent fundamental or natural period so that the shunt conden-

3309

ser jetts and the inductance coils 11, 12 are necessary to operativeness, then it will be evident that it requires invention to use two locals on one vertical conductor and all reference to such acidification would have to be eliminated. [illegible] thought to be the case, however, and the present requirement is limited to that of the last preceding para raph. In this connection it is pointed out that applicant has shown on the new drawings an arrangement of scherer and translating device in connection with a Planté cell and that he has in the amendment referred to a certain "e ection frame" for re ain ing the dielectric's core of the coil. This matter having no foundation in the original specification must be rejected to as involving a departure from the original disclosure and cancellation is required. The fact that applicant has in a co-pending application filed about one year after the filing of this case stated that the dielectric cell is well known in the art, does not [illegible] disclosure therein a description of the same as filed, cannot be studied by the [illegible] to be later than that of the [illegible] application of what we stated or said in the original specification. The original specification pointed out that old dielectric and electric cylinders must be carefully [illegible]

that can be relied upon for patentability of claims 7 and 8 over the patent to Lodge, 609,154, Aug. 16, 1898, of record, and as that is new to this application it must be objected to as new matter.

Page 16, line 3, "current" should be changed to circuit.

Certain of the claims, such as claim 1, involve an argument the soundness of which the office has no means of testing. Assuming that the simple harmonic wave in a closed vibrator, it does not necessarily follow that such simple harmonic wave can be transferred to the elevated conductor and from the latter to the other without change of form. The fact is that applicant has undoubtedly improved the form of wave by the use of closed tuned circuits having an extra loading coil and the Office is not in a position to affirm or deny anything more than this. Because of the undoubted improvements involved in the apparatus upon which the claim is based it is allowed, and all other claims containing the same implication of novel features will be allowed.

Claim 2 is on a different basis. It can take nothing from the words "simple harmonic" because it has long been understood that a circuit tuned to respond to a given fundamental frequency will always be more efficient when acted upon by a simple harmonic of said frequency. This claim is alternative in substance and objectionable for that reason, the function of one resonant circuit being different from that of a group of resonant circuits in so much as the former lacks the weeding out action of the latter. Considering it as concerning the first alternative it is met in Marconi, 627,650, June 27, 1899, of record. Tuning is never perfect and in order to avoid this reference it is necessary to show affirmatively that there can be no tuning possible with his construction. He gives full particulars and details of construction and there can be no difficulty in proving mathematically whether or not any tuning effect is possible with his apparatus. Claim 3 is also rejected on Lodge aforesaid, in which the waves received

are probably not simple harmonic. In connection with figure 12 a condenser is described as a substitute for the resistance w for connecting the coherer more closely with the receiving apparatus whereby it is stimulated. On page 1 it is stated as to the telegraph instrument that it is associated with a "subsidiary circuit capable of electric oscillations of the same particular frequency" as the sending station.

Claim 7 is rejected on Lodge aforesaid, wherein an open coil balances the capacity of the air condenser in which the area h is one plate and the ground the other.

Claim 8 is also rejected on the same patent, special reference being had to lines 17 to 29 of page 3.

Claim 11 differs from claim 2 only in that it specifies a plurality of resonant circuits associated with one elevated conductor. The latter feature was admitted in the description only because it did not involve invention in view of Pupin's multiplex system of telegraphy described in patent No. 640,515, and the claim which is otherwise the same as said claim 2 must be rejected on the same reference and for the same reasons.

Claims 7 and 8 are also rejected as involving new matter.

Claim 13 is merely for the use of Marconi's apparatus in the art pointed out by Lodge and it is accordingly rejected.

Claims 1, 3, 4, 5, 6, 9, 10, 12 and 14 are capable of an interpretation which would make them definitive of applicant's invention. They are accordingly allowed.

Examiner, Div. 14.

For the sake of clearness, claims 2,7,8,11, and 13 are canceled and the following substitute claims are filed:

"2. The method of absorbing the energy of free or unguided, simple harmonic, electro-magnetic signal waves of one frequency, to the exclusion of the energy of like waves of a different frequency, which consists in associating with an elevated conductor a circuit resonant to the frequency of the waves, the energy of which is to be absorbed.

"7. The method of rendering a circuit resonant to a given high frequency, which consists in balancing the reactance of an air condenser by the reactance of a coil, the amplitude of whose potential energy is small compared to the amplitude of its kinetic energy when it is supporting a current of said given high frequency.

"8. The method of constructing a coil to be used in a circuit to be resonant to a given high frequency, which consists in so proportioning the coil that the amplitude of its potential energy shall be small compared to the amplitude of its kinetic energy when supporting a current of given high frequency.

"11. The method of selectively receiving the energy of free or unguided simple harmonic electro-magnetic signal waves of different frequencies, each to the exclusion of the rest, which consists in receiving the same in an elevated conductor and translating or conveying the several energies of the resulting electrical oscillations, each to a separate circuit associated with said elevated conductor, and resonant to the frequency of the electro-magnetic waves, the energy of which it is to receive.

"13. The method of selectively receiving the energy of free or unguided simple-harmonic electro-magnetic signal waves of different frequencies, each to the exclusion of the rest, which consists in receiving the same in a plurality of elevated conductors, thereby developing in each elevated conductor electrical oscillations corresponding in frequency to the electro-magnetic waves received by it and in translating or conveying from each elevated conductor to the associated circuit the energy of the oscillations

electrical oscillation to the frequency of which said associated circuit is made resonant."

Add the following claims:

15 ~~14.~~ The method of absorbing the energy of free or unguided simple harmonic electro-magnetic signal waves of one frequency to the exclusion of the energy of like waves of different frequencies which consists in associating with an elevated conductor a group of circuits, each resonant to the frequency of the waves, the energy of which is to be absorbed.

16 ~~15.~~ The method of receiving the energy of simple harmonic electro-magnetic signal waves, which consists in receiving the same in an elevated conductor and translating or conveying the energy of the resulting electrical oscillations to an electrical translating device shunted around the terminals of one of the elements of a resonant circuit associated with said elevated conductor and attuned to the frequency of the electro-magnetic waves.

Commissioner of Patents,

Washington,D.C.

Sir:

With reference to the criticisms of the Examiner as to new matter,it is believed that none of them is well founded. The matter of inductive or conductive connection of circuits as well known alternatives is referred to on page 7 of the original specification in the early part of the paragraph beginning "In general if n simple circuits," etc.

Regarding the use of a Plante battery in lieu of a condenser of large capacity,it is to be observed that the equivalence of t these two devices for such purposes as the exclusion of a battery current from a circuit and the suppression of sparks at contacts was well recognized many years before the date of filing of the present application. The Examiner is respectfully referred to "Alternate Currents of Electricity" by Blakesley,published in 1885,in which the equivalence of a condenser of large but variable capacity and an electro-lytic cell is very closely and interestingly set forth. Moreover,on page 13,lines 2 to 7,inclusive,of the present specification as originally filed,the Examiner will find an instance in which applicant mentions a Plante battery and a condenser of large capacity as alternate forms. 4505-02

However,to facilitate [illegible] examination of the case,applicant has decided to accept the suggestion of the Examiner to cancel Figs.13 to 16 and substitute therefor new figures 13 to 17 sent herewith. To render the specification accurately descriptive of the new drawings,an amendment to it is also made,which for convenience is placed upon a separate paper.

The Examiner refers to the illustrative example of a precaution to be taken set forth in lines 14 to 16 of page 19 as a basis for his objection to the present specific statement that solid dielectrics should be eliminated as far as possible from the coils. Particular attention is called to the fact that the descriptive matter referred to is preceded by the broad unqualified statement that both electrostatic and magnetic hysteresis must be excluded from the resonant circuit.

Properly viewed,the reference to exclusion of solid dielectrics from the coils is merely a specific restatement of the above co-ordinate with and as much justified as the statements in lines 14 to 16,above quoted. There being adequate ground for the statement that solid dielectrics should so far as possible be excluded from the coils,the suggestion of a skeleton frame as an obvious expedient is entirely unimportant and further objection should not be urged.

Applicant cannot conceal the validity of the Examiner's ruling as to the phrase "small as compared to the kinetic energy" introduced into the specification [illegible] application by recent amendment. The Examiner rightly states,however,that the original disclosure of applicant justifies the description of the potential energy of the displacement currents in the coil by the word "small." Now this word "small" involves comparison,and comparison with things of like kind,and it seems clear therefore to applicant that when it is stated that the potential energy is small as compared to the kinetic energy,this is merely a more accurate statement of the fact that the potential energy is small. The [illegible] "Hodges" case,144, does not [illegible]

4 5 [illegible]

which the potential energy of displacement currents shall be small. In fact what is shown in that patent excludes any such idea.

The only passage in the Lodge patent cited which gives particular instruction with regard to the construction of the coils he employs, are as follows:

"Between either capacity area and its knob I place a syntonizing self-inductance coil - that is, a coil of wire or metallic ribbon h', preferably insulated with any solid or fluid insulator, as in Fig. 6, or in air, of shape suitable to attain greatest inductance with a given amount of resistance."

Again:

"In Fig. 7 the syntonizing-coil h' is shown as surrounding a large telegraph-insulator I."

Again:

"The self-inductance-coil represented at h' in all applicable figures is a coil of highly conducting wire or ribbon, well insulated by air or by some other medium, as already described, or else covered to a sufficient thickness with insulating material of such shape as to have maximum self-inductance for a given resistance, and it may be either a flat coil including a considerable plane area or it may be a cylindrical coil wound upon a finely-subdivided iron core, as shown at H in Fig. 3, the wire being either single-lapped or "bunched" or otherwise."

With reference to the examiner's criticism of claims 2, 11 and 13, applicant respectfully suggests that the Examiner must have overlooked the distinction heretofore made in the case between a circuit made resonant by adding a coil and a condenser, and the quasi resonance obtained by efforts to regulate both the capacity and inductance of the coil itself, which is apparently what is sought to be done by Tesla in his patent No. 645,576. The result of such quasi resonance, even if successfully obtained, will not be the absorbing or selective receiving of the energy of waves of one frequency to the exclusion of the energy of [illegible] frequency

quencies,and no method is disclosed in any of the references involving the employment of resonant circuits as distinguished from quasi resonant coils,in the manner and for the purposes disclosed by the applicant.

Applicant has disclaimed such quasi resonance in which distributed electro-static capacity of the coil itself is employed to diminish the impedence of the coil,because such distributed capacity diminishes the impedance of the coil not alone for one frequency,but for a very large number of frequencies,and is therefore not available for the purpose of making a circuit resonant to one frequency to the exclusion of other frequencies.

Applicant does not contend that there is no advantage to be gained by such a construction as that shown in the Marconi patent cited. He only contends that it is not useful for the purpose of selective signaling,where waves of one frequency are received to the exclusion of waves of other frequencies.

The Marconi patent cited does not profess to be for a system of selective signaling and is incapable of use as a selective system.

It does,however disclose a system whereby disturbance from atmospheric electricity is minimized,and is,in the opinion of applicant,adapted to such use.

It is believed that some of the claims may with advantage be amended for the sake of greater clearness,and that certain claims may well be added. These amendments and additions are also for convenience made in the separate paper before referred to.

With reference to the applicant's action in canceling Figs. 15 to 16,he begs to have it understood that he is advised that these Figures may contain certain novel arrangements which may be in themselves patentable to him,and hence that their cancelation in this case is not to be regarded as abandonment. Figs 15 16.

Respectfully,

H505

WITNESSES:

Argument & Brief
June 9 2

IN THE UNITED STATES PATENT OFFICE.

Room No.31, Serial No.4005,

Application of John Stone Stone,

For Let. Pat. for Improvement in Method of Selective Electric Signaling,

Filed February 3,1900,

In reply to Office letter of May 18,1900.

---

31 State street, Boston,

June 7 ,1900.

To the Commissioner of Patents,

Washington, D.C.

Sir:

Applicant finds that an error has occurred in the typewriting of the amendment of late May 28,1900, an explanatory passage has been omitted after the paragraph ending on line 24, page 3 thereof.

The paragraph thus omitted is explanatory of the bearing of the [illegible] patent to Lodge No.609,154, dated [illegible] of May 28th, and is as follows:

"[illegible] the matter of the inductance of the [illegible] substantially large. He therefore [illegible] displacement [illegible] between the turns entirely. His instructions to use metallic [illegible], to wind [illegible] insulation, to wind [illegible] insulation instead of a skeleton frame, to wind [illegible] upon a finely subdivided iron core, are all [illegible] to fall the use of such coils as are [illegible] lines 7 to 9 of the present specification."

Applicant therefore now submits the above quoted passage as [illegible] bearing of the [illegible] patent of record upon the special [illegible] of said [illegible] by the applicant.

Applicant further notes that in his argument of May 28,1902 he did not meet or more properly speaking, comment upon the following passage in the Office letter of May 13,1902.

"Certain of the claims,such as claim 1,involve an argument, "the soundness of which the Office has no means of testing. Assuming that the simple harmonic wave can be produced in a closed vibrator,it does not necessarily follow that such simple harmonic "wave can be transferred to the elevated conductor and from the "latter to the ether without change of form. The fact is that "applicant has undoubtedly improved the form of wave by the use of "closed tuned circuits having an extra loading coil and the Office "is not in a position to affirm or deny anything more than this. "Because of the undoubted improvement involved in the apparatus "upon which the claim is based,it is allowed,and all other claims "containing the same implication of novel feature will be allowed."

Applicant concurs with the Examiner in his view that if simple harmonic electric vibrations can be developed in a closed,i.e, a persistent,vibrator,it is not obvious that these vibrations can be transferred to the elevated conductor of a wireless telegraph system and thereby develop in the ether free or unguided,electromagnetic waves or radiation,also of a simple harmonic character.

But though such method of developing free or unguided electro magnetic waves or radiation of a simple harmonic character is not obvious,applicant nevertheless contends that he has proved,both by mathematical argument and by experiments,that if forced simple harmonic electric vibrations be impressed upon the elevated conductor of a wireless telegraph system,the resulting radiation of electric and magnetic force will also be simple harmonic and of the same frequency.

So far as the applicant is aware he was the first to discover and make public this fact.

He states that the mere fact that the electric vibrations which take place in the associated persistent oscillator are simple harmonic in character and that the vibations which take place in the elevated conductor are the forced vibrations which result

from impressing these simple harmonic vibrations on the elevated conductor, is enough to insure that the electric vibrations in the elevated conductor are also simple harmonic with respect to time and are of the same frequency as those of the oscillator which developed them. Because it has long been known that if a simple harmonic force act upon a mechanical or electric system, be it ever so complex in structure, the resulting forced vibrations will also be simple harmonic in character and of the same frequency as the force which gave them birth, except in the case where there is hysteresis. But in the case of an aerial conductor of a wireless telegraph system there is no hysteresis present, and the forced electric vibrations of the elevated conductor must therefore be of the same form and frequency as the vibrations of the oscillator which communicated them to the elevated conductor.

In respect to the foregoing, the Examiner is respectfully referred to the definition of forced vibration given in "The Theory of Electricity and Magnetism" by A.G.Webster, Article 248, page 489, which is as follows:

"An oscillation whose period is that of force, as in our "present case, is called a forced oscillation or vibration in "contra-distinction to the case of the previous section, where "no force being applied, the period is governed by the constants of the system, and the oscillation is called a free "oscillation."

Also "The Theory of Sound" by Lord Rayleigh, First Edition, 1877, Article 46, pages 41 and 42, which is as follows:

"The distinction between forced and free vibrations is "very important, and must be clearly understood. The period "of the former is determined wholly by the force which is "supposed to act on the system from without; while that of "the latter depends only on the constitution of the system "itself. Another point of difference is that so long as the "external influence continues to operate, a forced vibration "is maintained, being represented strictly by a harmonic function. The free vibration gradually dies away, becoming "insensible after a time."

Also the present application,page 8,lines 10 to 23:

"But besides the ability to execute natural vibrations "or oscillations,both electric and mechanical systems are "capable of supporting what are termed <u>forced vibrations</u> and "in the case of forced vibrations,the period of the vibration is independent of the electro-magnetic constants of the cir- "cuit on the one hand,and the mechanical constants of the me- "chanical system on the other hand,and depends only upon the "period of the impressed force. Thus if a simple harmonic "electro-motive force be impressed upon a circuit free from "hysteresis,whether it be a simple circuit,or a complex of "simple circuits,the forced vibrations or currents resulting "from the impressed force will also be simple harmonic,and "of the same period as that of the impressed force."

Also present application,page 10,lines 19 to 26:

"In order that the vertical conductor at the transmit- "ting station shall generate harmonic electro-magnetic waves "of definite frequency,I cause the electric vibrations in said conductor to be of a simple harmonic character and "this in turn I accomplish by producing what are substantial- "ly forced electric vibrations in the vertical conductor in "lieu of producing natural vibrations in the conductor as "has heretofore been practised."

Further it may be thus shown that the vibrations of the [illegible] are forced simple harmonic electric vibrations [illegible] frequency as those impressed upon it by the associated [illegible] oscillator,it is still true that the free or un- [illegible] electro-magnetic wave or radiation will also be of a [illegible] and of the same frequency as the elec- [illegible] elevated conductor. Fortunately,however,for [illegible] discussion of the Hertz oscillator,as given by [illegible] can be made available to show that the electro-magnetic [illegible] simple harmonic transaction and of the same [illegible] as the vibrations in the associated conductor. Though the

Though the electric vibrations which Dr.Hertz employed in his experiments with what is known as his dumb bell oscillator,were not forced simple harmonic vibrations,but were the natural vibrations of the oscillator,nevertheless in his mathematical interpretation of his results,he employed a solution strictly applicable only to the case of forced simple harmonic vibrations in the oscillator.

In order not to encumber the case with lengthy mathematical expressions,the Examiner is asked to consult either "Electric Waves," by Dr.Heinrich Hertz,in the original or in the translation by D.E. Jones, Macmillan & Co.,1893; or "The Theory of Light," by Thomas Preston, Second Edition,1895; or "Absolute Measurements in Electricity and Magnetism," by A.Gray,1893,Vol.2,part 2,chap.14,section 3,in each of which Hertz' analysis of the operation of his dumb bell oscillator,when executing simple harmonic electric vibrations,is given. By referring to the equations for the electric and magnetic forces in the medium surrounding the oscillator,the Examiner will find that in the equatorial plane of the oscillator,however far it be extended,the magnetic force is always parallel to the plane,that the electric force is always normal to the plane,and that the potential is zero throughout the plane. It follows directly from these considerations that if a conducting sheet be extended through this equatorial plane,no current will be developed in the sheet and no disturbance of the field of force can result,since no lines of magnetic force will cut the conducting sheet, and there will be no component of electric force parallel to the sheet. If the conducting sheet be infinitely conductive,it follows that all that goes on below the sheet may be eliminated,leaving only a conductor extending vertically from the conducting sheet,and bearing at its extremity a capacity area. Such an arrangement is substantially the same as the vertically elevated conductor of a wireless telegraph system extending vertically from the conductive surface of the earth and terminating in a capacity area at its extremity. It follows,therefore,that the solution given by Dr.Hertz for the radiation emanating from his dumb bell oscillator executing simple harmonic vibrations is directly applicable to the problem of the elevated conductor in a wireless telegraph system.

executing simple harmonic electric vibrations. Now since simple harmonic electric vibrations in the Hertz oscillator give rise to simple harmonic electro magnetic radiation, so also must simple harmonic electric vibrations in the elevated conductor of a wireless telegraph system give rise to simple harmonic electro magnetic radiation.

These considerations show, therefore, that the forced simple harmonic electric vibrations of the elevated conductor would give birth to electro-magnetic waves, also simple harmonic in character, and of the same period as the electric vibrations forced in the elevated conductor

So far as applicant is aware, he was the first to discover and point out the application of Hertz' analysis to the elevated conductor of a wireless telegraph system.

Applicant feels that this argument is sufficient comment upon the paragraph quoted at the beginning of this letter from the Office letter of May 13, 1902. Nevertheless, it is worth noting that he does not contend that either the vibrations in the elevated conductor, or the radiations emanating therefrom, are absolutely simple harmonic in character, such perfection of wave form being unattainable in any practical apparatus. Moreover, when a simple harmonic force is impressed upon a system having a natural rate of vibration of its own, there is always more or less of the natural vibration developed, and it is worth noting that in the important cases when the elevated conductor of a wireless telegraph system has a fundamental which is of the same frequency as the forced vibrations impressed upon it, the natural vibrations excited will not interfere with the wave form. Again if the elevated conductor be aperiodic, no natural vibrations will be set up in it when the forced vibrations are impressed, and the form of the forced vibrations will therefore not be disturbed. It is only in the case where the elevated conductor has a very pronounced selectivity of its own, that the impressing of forced vibrations upon it of a different frequency from its natural frequency will develop natural vibrations seriously interfering with the wave form of the vibrations developed in it.

It will also be noted that in the above [illegible], in passing from the consideration of the Hertz oscillator to [illegible] of

the vertical wire oscillator, the conducting sheet supposed to extend through the equatorial plane, was assumed to be infinitely conductive, and could not, therefore, represent with absolute accuracy the surface of the earth. In this connection it is to be noted that the potentials involved in wireless telegraphy are very large compared to those used in any of the other commercial applications of electricity, whereas the currents employed are in general relatively small compared to those which occur in some of the other applications of electricity, and furthermore, it must be remembered that in order to seriously disturb the potential of the earth at a given point, it is necessary to discharge into it an excessively large current as measured by these standards. It follows, therefore, that though the imperfect conductivity of the earth's surface may make it necessary to slightly modify the Hertz analysis, in order that it may strictly apply to the elevated conductor oscillator, yet such modification must result in an extremely minute correction, so long as the plane of the earth's surface is not seriously irregular in the immediate neighborhood of the elevated conductor.

Applicant sends herewith a sheet containing a lithographic fac simile of Fig. 12 of the drawings, from which it was requested in a further communication that a certain portion be erased. The erasure desired is represented upon the fac simile in red ink.

Respectfully,

Alex. P. Brown

Att'y for Applicant.

Serial No. 4505 Paper No. 13

Amendt E

Filed June 19 1902

IN THE UNITED STATES PATENT OFFICE.

--o--

Application of John Stone Stone,

Method of Selective Electric Signaling,

Filed Feb. 8, 1900, Ser. No. 4,505

--o--

Hon. Commissioner of Patents.

Sir:-

The various claims heretofore made in this case having been made at different times, and consequently being deemed lacking in harmony of nomenclature, it is considered desirable to cancel them and substitute others in their place, the latter differing only in phraseology. It has further been deemed desirable to add certain claims. Accordingly, applicant amends by canceling all the present claims and substituting the following:

16

"1. The method of developing free or unguided simple harmonic electro-magnetic waves of a definite frequency, which consists in producing forced simple harmonic vibrations of the same frequency in an elevated conductor.

8

The method of transmitting the energy of free simple harmonic electro-magnetic waves of [illegible] like waves [illegible] which consists in associating [illegible] the frequency of [illegible] as by the Abderhold.

The method of distributing the energy of free

or unguided electro-magnetic waves which consists in independently developing forced simple harmonic electric vibrations of different frequencies in an elevated conductor and receiving the several energies of the resulting electro-magnetic waves of different frequencies, each to the exclusion of the rest, in a separate electric translating device.

4. The method of distributing the energy of free or unguided electro-magnetic waves which consists in independently developing a number of forced simple harmonic electric vibrations of different frequencies in an elevated conductor and receiving the several energies of the resulting electro-magnetic waves, of different frequencies, each to the exclusion of the rest, in a separate circuit resonant to the same frequency as that of the waves, the energy of which is to be absorbed therein.

5. The method of distributing the energy of free or unguided electro-magnetic waves which consists in developing forced simple harmonic electric vibrations of different frequencies, each in a different elevated conductor, and receiving the several energies of the resulting electro-magnetic waves of different frequencies, each to the exclusion of the rest, in a separate electric translating device.

6. The method of distributing the energy of free or unguided electro-magnetic waves which consists in developing a number of forced simple harmonic electric vibrations of different frequencies, each in a different elevated conductor and receiving the several energies of the resulting electro-

magnetic waves of different frequencies, each to the exclusion of the rest, in a separate resonant circuit attuned to the same frequency as that of the waves, the energy of which is to be absorbed therein.

7. The method of rendering a circuit resonant to given high frequency, which consists in balancing the reactance of an air condenser by the reactance of a coil, the amplitude of whose potential energy is small compared to the amplitude of its kinetic energy when it is supporting a current of said given high frequency.

8. The method of constructing a coil to be used in a circuit to be made resonant to a given high frequency which consists in so proportioning the parts that the amplitude of its potential energy shall be small compared to the amplitude of its kinetic energy when supporting a current of given high frequency.

9. The method of developing free or unmodified simple harmonic electro-magnetic signal waves, which consists in passing from a condenser through a closed circuit having inductance adapted to produce under such conditions simple harmonic vibrations, and impressing the electro-magnetic waves so produced upon an open circuit or elevated conductor substantially as described.

10. The method of developing free or unmodified simple harmonic electro-magnetic signal waves which consists in discharging a condenser through a closed circuit having inductance adapted to produce under such conditions simple harmonic vibrations, impressing these waves upon

circuit or group thereof resonant to the frequency of these vibrations, and impressing the resulting electrical vibrations upon an open circuit or elevated conductor.

11. The method of selectively receiving the energy of free or unguided simple harmonic electro-magnetic signal waves of different frequencies, each to the exclusion of the rest which consists in receiving the same in an elevated conductor and translating or conveying the several energies of the resulting electrical oscillations, each to a separate circuit associated with said elevated conductor, and resonant to the frequency of the electro-magnetic waves, the energy of which it is to receive.

12. The method of selectively receiving the energy of simple harmonic electro-magnetic signal waves of different frequencies, each to the exclusion of the rest, which consists in receiving the same in an elevated conductor and translating or conveying the several energies of the resulting electrical oscillations, each to a separate group of resonant circuits associated with said elevated conductor and resonant to the [illegible] electro-magnetic waves the energy of which it is to receive.

[illegible] selectively receiving the energy [illegible] electro-magnetic signal [illegible] sion of the [illegible] in a plurality of [illegible] developing in such elevated conductor electrical oscillations corresponding in frequency to [illegible] waves [illegible] in translating

or conveying from each elevated conductor to an associated circuit the energy of the particular electrical oscillations to the frequency of which said associated circuit is made resonant.

11. The method of selectively receiving the energy of simple harmonic electro-magnetic signal waves of different frequencies, each to the exclusion of the rest, which consists in receiving the same in a plurality of elevated conductors, thereby developing in each elevated conductor electrical oscillations corresponding in frequency to the electro-magnetic [redacted] conveying from each elevated conductor to a group of resonant circuits associated therewith the energy of the particular electrical oscillations to the frequency of which said group of associated circuits is resonant.

12. The method of absorbing the energy of free or unguided simple harmonic electro-magnetic signal waves of one frequency to the exclusion of the energy of like waves of different [illegible] which consists in associating with an elevated conductor [illegible] resonant to the frequency of the wave [illegible] which is to be absorbed.

20

13. The method of receiving the energy of simple harmonic electro-magnetic signal waves, which consists in receiving the same in an elevated conductor and [illegible] conveying the energy of the resulting electrical oscillations to an electrical translating device and [illegible] terminals of [illegible] associated therewith.

frequency of the electro-magnetic waves.

17. The method of distributing the energy of free or unguided electro-magnetic waves, which consists in independently developing a number of forced simple harmonic electric vibrations of different frequencies in an elevated conductor and receiving the several energies of the resulting electro-magnetic waves of different frequencies, each to the exclusion of the rest, in a group of circuits resonant to the same frequency as that of the waves the energy of which is to be absorbed therein.

18. The method of distributing the energy of free or unguided electro-magnetic waves, which consists in developing a number of forced simple harmonic electric vibrations of different frequencies each in a different elevated conductor, and receiving the several energies of the resulting electro-magnetic waves of different frequencies, each to the exclusion of the rest, in a separate group of circuits [illegible] frequency as that of the waves the energy [illegible] absorbed.

19. [illegible] of developing free or unguided simple harmonic electro-magnetic signal waves, which consists in disturbing the electrical equilibrium of a circuit containing a condenser, and a coil having inductance adapted [illegible] under such conditions simple harmonic vibrations. [illegible] the electrical vibrations so produced upon an [illegible] or elevated [illegible] described

[illegible]

455 - F2

in disturbing the electrical equilibrium of a circuit comprising a condenser and a coil having inductance adapted to produce under such conditions simple harmonic vibrations, impressing these vibrations on a resonant circuit or , ing thereof attuned to the frequency of these vibrations, and impressing the resulting electrical vibrations upon [illegible] circuit or elevated conductor.

1. The method of receiving the energy of simple harmonic electro-magnetic signal waves, which consists in collecting the same in an elevated conductor and in translating the energy of the resulting electrical oscillations by an electrical translating device forming one of the elements of a resonant circuit associated with said elevated conductor and resonant to the frequency of the electro-magnetic waves.

2. The method of developing true or undamped simple harmonic electro-magnetic signal waves or radiations, which consists in disturbing the electrical equilibrium of a closed oscillating circuit containing a condenser and a coil having sufficient auxiliary inductance to produce under such conditions simple harmonic electrical oscillations, impressing such oscillations upon a resonant circuit associated with the elevated conductor.

3. The method of developing true or undamped simple harmonic electro-magnetic signal waves or radiations, which consists in disturbing the electrical equilibrium of a closed oscillating circuit containing a condenser and a coil having sufficient auxiliary inductance to produce under such conditions simple harmonic electrical oscillations, impressing such oscillations upon a resonant circuit associated with the elevated conductor, [illegible] of the [illegible]

4565 53

...effect of the mutual inductance between it and the ... circuits of the group and between it and the elevated conductor.

24. The method of developing free or unguided ... simple harmonic electro-magnetic signal waves or radiations, of different frequencies independently in a single elevated conductor, which consists in disturbing the electrical equilibrium of closed oscillating circuits associated with said elevated conductor, each being attuned to a different ... of the frequencies to be developed, and each of said oscillating circuits having sufficient auxiliary inductance to swamp the effect of the mutual inductance between it and the other oscillating circuits and the said elevated conductor.

25. The method of receiving the energy of simple harmonic electro-magnetic waves of a given frequency, to the exclusion of like waves of different frequencies, which consists in receiving the same in an elevated conductor and conducting the energy of the resulting electrical oscillations to a circuit associated with the elevated electrical conductor and made ... to the frequency of the electro-magnetic waves to be received, and which is to be received on a condenser ... auxiliary inductance coil whose inductance is sufficient to swamp the effect of the mutual inductance between the associated circuit and the elevated conductor.

26. The method of selectively receiving the energy of simple harmonic electro-magnetic signal waves of one frequency, to the exclusion of like waves of different frequencies, which consists in receiving the same in an elevated

conductor and translating or conveying the energies of the resulting electrical oscillations each to a separate circuit associated with said elevated conductor, each resonant to the frequency of the electro-magnetic waves, the energy of which is to be received, and each having sufficient auxiliary inductance to swamp the effect of the mutual inductance between it and the other associated circuits and between it and the elevated conductor.

27. The method of developing simple harmonic, electro-magnetic, signal waves or radiations of a given frequency, which consists in impressing upon a metallically continuous vertical oscillator forced simple harmonic electrical oscillations of the same frequency.

28. The method of simultaneously developing simple harmonic, electro-magnetic, signal waves or radiations of different frequencies, which consists in independently impressing upon a metallically continuous vertical oscillator forced, simple harmonic, electrical oscillations of the same frequencies.

29. The method of absorbing the energy of free or unguided, simple harmonic, electro-magnetic signal waves of one frequency, the exclusion of the energy of like waves of different frequency, which consists in associating with an elevated conductor a circuit resonant to the frequency of the waves the energy of which is to be absorbed, and having sufficient auxiliary inductance to swamp the effect of the mutual inductance between it and the elevated conductor.

30. The method of distributing the energy of free or unguided, electro-magnetic waves, which consists in independently developing a number of forced, simple harmonic electric vibrations of different frequencies in an elevated conductor, and receiving the several energies of the resulting electro-magnetic waves of different frequencies, each to the exclusion of the rest in a separate circuit resonant to the same frequency as that of the waves, the energy of which is to be absorbed, and having sufficient auxiliary inductance to swamp the effect of the mutual inductance between it and all of the circuits with which it is associated.

31. The method of distributing the energy of free or unguided, electro-magnetic waves, which consists in developing a number of forced, simple harmonic, electric vibrations of different frequencies, each in a different elevated conductor, and receiving the several energies of the resulting electro-magnetic waves of different frequencies, each to the exclusion of the rest, in a separate resonant circuit attuned to the same frequency as that of the waves, the energy of which is to be absorbed therein, and having sufficient auxiliary inductance to swamp the effect of the mutual inductance between it and all circuits with which it is associated.

32. The method of developing free or unguided, simple harmonic, electro-magnetic signal waves, which consists in discharging a condenser through a closed circuit having inductance adapted to produce under such conditions simple

harmonic vibrations and sufficient auxiliary inductance to swamp the effect of the mutual inductance between it and an elevated conductor with which it is associated, and impressing the electrical vibrations so produced upon the said elevated conductor.

33. The method of developing free or unguided, simple harmonic, electro-magnetic, signal waves, which consists in discharging a condenser through a closed circuit having inductance adapted to produce under such conditions simple harmonic vibrations, impressing these vibrations on a resonant circuit or group thereof resonant to the frequency of these vibrations, each circuit having sufficient auxiliary inductance to swamp the effect of the mutual inductance between it and all circuits with which it is associated, and impressing the resulting electrical vibrations upon an open circuit or elevated conductor.

34. The method of selectively receiving the energy of free or unguided, simple harmonic, electro-magnetic, signal waves of different frequencies, each to the exclusion of the rest, which consists in receiving the same in an elevated conductor and translating or conveying the several energies of the resulting electrical oscillations, each to a separate circuit associated with said elevated conductor, and resonant to the frequency of the electro-magnetic waves, the energy of which it is to receive, each circuit having sufficient auxiliary inductance to swamp the effect of the mutual inductance between it and all circuits with which it is associated.

35. The method of selectively receiving the energy of simple harmonic, electro-magnetic, signal waves of different frequencies, each to the exclusion of the rest, which consists in receiving the same in an elevated conductor and translating or converting the several energies of the resulting electrical oscillations, each to a separate group of resonant circuits associated with said elevated conductor and resonant to the frequency of the electro-magnetic waves, the energy of which it is to receive, each circuit having sufficient auxiliary inductance to swamp the effect of the mutual inductance between it and all circuits with which it is associated.

36. The method of selectively receiving [redacted] of free or unguided, simple harmonic, electro-magnetic signal waves of different frequencies, each to the exclusion of the rest, which consists in receiving the same in a plurality of elevated conductors, thereby developing in each elevated conductor electrical oscillations corresponding in frequency to the electro-magnetic waves received by it and in translating or conveying from each elevated conductor to an associated circuit the energy of the particular electrical oscillations to the frequency of which said associated circuit is made resonant, each of said circuits having sufficient auxiliary inductance to swamp the effect of the mutual inductance between it and the elevated conductor and all circuits with which it is associated.

37. The method of selectively receiving the energy of simple harmonic, electro-magnetic, signal waves of differ-

24

...ent frequencies, each to the exclusion of the rest, a set com-
...prising at least one and the same in a plurality of elevated con-
...ductors, thereby developing in each elevated conductor
electrical oscillations corresponding in frequency to the
electromagnetic waves received by it and in response to
conveying from each elevated conductor to a group of resonant
circuits associated therewith the energy of the particular
electrical oscillations to the frequency of which said group
of associated circuits is resonant, ... the
...ing sufficient auxiliary inductance to change the effect of the
mutual inductance between it and each of the other
all circuits with which it is associated.

38. ... the art of ... unguided, simple harmonic, electro-magnetic, signal waves of one frequency to the exclusion of the energy of like waves of different frequencies, which consists in receiving from ... elevated conductor a group of circuits, each resonant to the frequency of the wave ... and ... ted, each circuit having ... sufficient ... to change the effect of the mutual inductance between it and the other circuits with which it is associated.

39. ... the art of ... simple harmonic, electro-magnetic signal waves, ... consisting in receiving the same in an elevated conductor ... and ... in conveying the energy of the resulting electrical oscillations to an electrical translating device ... and the terminals of one of the elements of a resonant circuit associated with said elevated conductor and resonant to the

frequency of the electro-magnetic waves, each circuit having sufficient auxiliary inductance to swamp the effect of the mutual inductance between it and all circuits with which it is associated.

40. The method of distributing the energy of free or unguided electro-magnetic waves, which consists in independently developing a number of forced, simple harmonic, electric vibrations of different frequencies in an elevated conductor and receiving the several energies of the resulting electro-magnetic waves of different frequencies, each to the exclusion of the rest, in a group of circuits resonant to the same frequency as that of the waves, the energy of which is to be absorbed therein, each circuit having sufficient auxiliary inductance to swamp the effect of the mutual inductance between it and all circuits with which it is associated.

41. The method of distributing the energy of free or unguided electro-magnetic waves, which consists in developing a number of forced, simple harmonic, electric vibrations of different frequencies, each in a different elevated conductor, and receiving the several energies of the resulting electro-magnetic waves of different frequencies, each to the exclusion of the rest, in a separate group of circuits resonant to the same frequency as that of the waves the energy of which is to be absorbed, each of said circuits having sufficient auxiliary inductance to swamp the effect of the mutual inductance between it and the elevated conductor and all circuits with which it is associated.

42. The method of developing free or unguided,

simple harmonic, electro-magnetic signal waves, which consists in disturbing the electrical equilibrium of a circuit comprising a condenser, and a coil having inductance adapted to produce under such conditions simple harmonic vibrations, and impressing the electrical vibrations so produced upon an elevated conductor, each circuit having sufficient auxiliary inductance to swamp the effect of the mutual inductance between it and all circuits with which it is associated.

43. The method of developing free or unguided, simple harmonic, electro-magnetic signal waves, which consists in disturbing the electrical equilibrium of a circuit comprising a condenser and a coil having inductance adapted to produce under such conditions simple harmonic vibrations, impressing these vibrations on a resonant circuit or group thereof attuned to the frequency of these vibrations, and impressing the resulting electrical vibrations upon an elevated conductor each circuit having sufficient auxiliary inductance to swamp the effect of the mutual inductance between it and all circuits with which it is associated.

44. The method of receiving free or unguided, simple harmonic, electro-magnetic signal waves, which consists in receiving the same in an elevated conductor and translating or converting the energy of the resulting electrical oscillations to an electrical translating device forming one of the elements of a resonant circuit associated with said elevated conductor and resonant to the frequency of the electro-magnetic waves, each circuit having sufficient auxiliary inductance to swamp the effect of the mutual inductance between it and all circuits with which it is associated.

Washington
June 15 1903

4505- Paper 14

Filed June 19 1902

IN THE UNITED STATES PATENT OFFICE.

Room No. 91. Serial No. 4505.

Application of John Stone Stone,

For Patent for Improvement in Method of Selective Electric Signaling.

Filed Feb. 8, 1900.

Hon. Commissioner of Patents,

Washington, D.C.

Sir:-

Applicant observes that in his amendment of May 28, 1902 he so amended his case as to make it read "It is to be here noted that the above described methods of simultaneously transmitting and receiving space telegraph messages by a common elevated conductor are not described as the preferred methods", etc.

As this passage is not in his judgment sufficiently explained in the text of his application, he amends by inserting after the word "methods", line 9, page 7, amendment of April 8, 1902, the following: "since the branch circuits V V, in Figs. 16 and 17 are not in themselves selective, and since the elevated conductors in Figs. 13 and 14 contain a number of induction coils in series, not essential to the operation of any one of the stations singly,"

Applicant amends by introducing after the paragraph to which the foregoing amendment applies, the following paragraph:

"The branch circuits V V, of Fig. 17 are not selective since they contain but one element of a tuned circuit, viz.,

4505- 93

the inductance of M and M_1. Vibratory currents of whatever frequently they may be, communicated by the vertical wire to these circuits, will divide amongst them in simple inverse proportion to their electro-magnetic impedances and are not selective except for a slight reaction due to the associated circuits C' M' L' and C'_1 M_1 L'_1. These reactions, so far from tending to make the branches selective to the frequencies to which their associated circuits are intended to respond, will in fact, cause them to oppose more strongly currents of these frequencies than those to which the associated circuits are not attuned. Again it is obvious that the inductance of the coil M in Fig. 13 is merely an additional impedance in the elevated conductor, which, to say the least, cannot assist in the development of vibrations in the elevated conductor impressed by circuit C'_1 M'_1 L'_1 M_1. The same is obviously true of the coil M_1 in the elevated conductor with reference to the operation of the circuit C' M' L'. Now passing to the transmitting station shown at Fig. 16, it is obvious that the vibrations communicated by the circuit C' M' L' to the elevated conductor M are subject to a shunt due to the coil M_1 in the other branch of the elevated conductor, and conversely the vibrations developed in the elevated conductor by the associated circuit C'_1, M'_1, L'_1, are subject to a shunt due to the coil M in the other branch of the elevated conductor. Finally, the coil M in the elevated conductor in Fig. 14 can at best only present an impedance to the waves intended to be received by the circuit C', M', L', and conversely the coil M_1 in the elevated conductor can at best only present an impedance to the vibrations intended to be received by the circuit C' M' L'.

Amend the specification by inserting at the end thereof, and immediately before the claims, the following:

"In this specification I have described the development of free or unguided electro-magnetic signal waves of a given frequency, by employing in association with an elevated conductor, a circuit such as to produce therein forced simple harmonic electric vibrations of the frequency desired. I have also described a method of receiving or absorbing the energy of free or unguided simple harmonic electro-magnetic waves of one frequency to the exclusion of waves of a different frequency by associating with an elevated conductor a circuit made resonant to the frequency of the waves whose energy is to be absorbed. The circuit whereby forced simple harmonic electric vibrations are produced in the elevated conductor I have shown as a circuit containing a condenser and a self-induction coil so proportioned as to make the natural vibrations of a frequency which is the frequency of the vibrations to be forced or impressed in an elevated conductor. The circuit whereby the energy of the electro-magnetic waves of one frequency is absorbed to the exclusion of that of waves of other frequencies is in like manner a circuit containing a condenser and a self-induction coil so proportioned as to make the circuit resonant to a frequency which is the frequency of the waves, the energy of which is to be received. Both of the circuits I have spoken of are tuned circuits, and they may be conveniently distinguished with reference to their respective functions by denominating the circuit employed in the development of the vibrations as an oscillating or sonorous circuit, and by denominating the circuit employed in the reception or absorption of the vibrations as a resonant

circuit. I prefer to make this discrimination in nomenclature for the reason that while both the circuits are resonant circuits yet functionally only that one employed for receiving or absorbing is accurately so described.

Except for this distinction in function it is well to note that all oscillating or sonorous circuits are resonant circuits but only such resonant circuits as have their resistance less than the square foot of the ratio of four times their inductance by their capacity are oscillating or sonorous circuits.

Also throughout this specification I have described the electrical oscillations or vibrations and the free or unguided electro-magnetic waves or radiations as simple harmonic.

[redacted]

It is the object of my present invention to approach as nearly as possible to perfect simple harmonic wave, and such object is attained to within such a degree of precision as to preclude any interference with the operation of the system by any possible departure that may exist in the wave from the absolute simple harmonic form. My reason for confining the description of the electrical oscillations or vibrations and the electro-magnetic waves or vibrations to the simple harmonic type is that, in the operation of the system, only the simple harmonic components are effective in carrying out the object of the invention. Though it is impossible to prevent the presence of the minute overtones accompanying these simple harmonic waves, such overtones do not only do not contribute to the useful operation of the system, but may in fact operate as to such useful and complete operation, unless their amplitude be excessively small as is the case in the present invention.

It is for this reason that I have taken every precaution to approximate as closely as may be to the true or absolute simple harmonic wave-form, thereby reducing to a minimum the over tones which cause a departure from the true sine wave.

Specifically, though it may be possible to employ the purposes of multiple and selective wireless telegraphy W. T. electric vibrations and radiations departing considerably from the simple harmonic type by employing at the receiving end circuits selective to the fundamental of such vibrations and radiations, yet it will only be through the selective reception of that simple harmonic component of the vibrations or radiations which is their fundamental that the system will be operative. The other simple harmonic components of the vibrations or radiations add nothing to the operation of the system.

Moreover, if such over tones exist in the waves emenating from a transmitting station, their presence will preclude the possibility of placing receiving stations in the immediate neighborhood of such transmitting station for the reception of signal waves of frequencies corresponding to the frequencies of such over tones."

Amend the specification by inserting at line 15, page 15 thereof, the following:

The mathematical expression for the frequency to which a circuit is resonant when it is isolated from all other circuits i.e. has but a single degree of freedom is well known and may be stated as follows:-

$$n = \frac{1}{2\pi\sqrt{C_1 L_1}}$$ from which

$$L_1 = \frac{1}{C_1 p^2}.$$

where [illegible] is the frequency, C_1 is the capacity, L_1 is the inductance and p is the periodicity which equals $2\pi n$.

In the case of a circuit of two degrees of freedom, however, in order to make the comporant circuits each responsive to the same frequency as when isolated, in other words to overcome the modifying effect of the mutual inductance of each circuit upon the other, it necessary to consider, in the case of inductive relation, the expression:-

$$\frac{1}{C_1 p^2} = L_1 - \frac{M_{12}^2 p \left(L_2 p - \frac{1}{C_2 p}\right)}{R_2^2 + \left(L_2 p - \frac{1}{C_2 p}\right)^2},$$

where C_1 L_1 are the capacity and inductance of the first circuit C_2, L_2, R_2 are the capacity, inductance and resistance, respectively of the second circuit and M_{12} is the mutual inductance of the circuits.

From these expressions careful consideration will show that the effective inductance of the first circuit has been modified by its inductive relation with the second circuit and it is:-

$$L_1' = L_1 - \frac{M_{12}^2 p \left(L_2 p - \frac{1}{C_2 p}\right)}{R_2^2 + \left(L_2 p - \frac{1}{C_2 p}\right)^2}$$

Similarly we have to consider the expression:-

$$\frac{1}{C_2 p^2} = L_2 - \frac{M_{12}^2 p \left(L_1 p - \frac{1}{C_1 p}\right)}{R_1^2 + \left(L_1 p - \frac{1}{C_1 p}\right)^2},$$

from which it will be seen that the effective inductance of the second circuit has been modified by its inductive relation with the first circuit and is:

$$L'_1 = L_1 - \frac{M^2 p (L_2 p - \frac{1}{C_2 p})}{R_2^2 + (L_2 p - \frac{1}{C_2 p})^2}$$

These two inductances L'_1 and L'_2 are the apparent inductances which each of these circuits would have if acting as the primary to induce simple harmonic vibrations of frequency n in the other.

It is therefore necessary in order to overcome the modifying effect of the mutual inductance on either circuit to add to that circuit an auxiliary inductance coil of inductance large compared to the term of the form :-

$$\frac{M^2 p (L_2 p - \frac{1}{C_2 p})}{R_2^2 + (L_2 p - \frac{1}{C_2 p})^2}$$

, or at least as large [illegible] added to the natural inductance of the circuit, the sum of these inductances being very large compared to the said Term.

Respectfully,

Alex P. Brown,

Letters should be addressed to "Commissioner of Patents, Washington, D. C."

DEPARTMENT OF THE INTERIOR.

U. S. Patent Office.

Washington, D. C., [illegible] 20, 1903.

SIR.—Your APPLICATION for a patent for an IMPROVEMENT IN [illegible]

Filed [illegible], has been examined and ALLOWED.

The final fee, Twenty Dollars, must be paid, and the Letters Patent bear date as of a day not later than SIX MONTHS from the time of the present notice of allowance.

If the final fee is not paid within that period the patent will be withheld, and your only relief will be by a renewal of the application, with additional fees, under the provisions of Sec. 4897, Revised Statutes. The Office aims to deliver patents upon the day of their date, and on which their term begins to run. But to do this properly applicants will be expected to pay their final fees at least TWENTY DAYS prior to the expiration of the six months allowed them by law. The printing, photolithographing, and engraving of the several patent parts, preliminary to final signing and sealing, will consume the intervening time, and such work will not be done until after payment of the necessary fees.

When you send the final fee you will also send, DISTINCTLY AND PLAINLY WRITTEN, the name of the INVENTOR and TITLE OF INVENTION AS ABOVE GIVEN, DATE OF ALLOWANCE (which is the date of this circular), DATE OF FILING, and, if assigned, the NAMES OF THE ASSIGNEES.

If you desire to have the patent issue to ASSIGNEES, an assignment containing a REQUEST to that effect, together with the FEE for recording the same, must be filed in this Office on or before the date of payment of final fee.

Additional copies of Specifications and Drawings will be charged for at the following rates: Single Copies, unmounted, 5 cents each. The money should accompany the order.

Very respectfully,

F. I. Allen.

Commissioner of Patents.

IN REMITTING THE FINAL FEE GIVE THE SERIAL NUMBER AT THE HEAD OF THIS NOTICE.

If payment is made by check or draft, the credit allowed is subject to the collection of the same.

After allowance, and prior to payment of the final fee, copies will be furnished carefully examining the description to see that their statements and language are correct. Any mistakes not occurred through the fault of the officers, and not affecting the merits of the case, will not be corrected after the delivery of the letters patent to the inventor or his agent.

Petition of Edwin A. Allen

No. 61569

Method of Adjusting Electric Signaling

for recommendation

F. A. Allen

Commissioner of Patents

Serial No. 4506 Patented 16
Amendt H (Rule 78)
Filed Nov. 4 1902

IN THE UNITED STATES PATENT OFFICE.

Room #91, Serial No. 4506.

Application of John Stone Stone,

For Patent for Method of Selective Electric Signaling.

Filed February 8,1900. Allowed June 26,1902.

31 State Street,
Boston,Mass. Nov. 3,1902.

Hon, Commissioner of Patents,

Washington, D.C.

Sir:-

It is respectfully requested that the following claim be entered in the above entitled application under Rule 78, without withdrawing the case from issue.

45. The method of absorbing the energy of free or unguided simple harmonic electro-magnetic signal waves of one frequency, to the exclusion of the energy of like waves of different frequency, which consist in receiving the same in an elevated conductor and translating or conveying the resulting electric vibrations to a circuit associated with said elevated conductor, and resonant to the frequency of the waves, the energy of which is to be received.

It is believed that this claim is patentable, and that it may be allowed without further search on the part of the Office.

Respectfully,

John Stone Stone

Applicant.

The claim is patentable and it is recommended that the amendment be entered under Rule 78 without withdrawing the case from issue. The final fee has not been paid.

JOHN STONE STONE

Nov. 19, 1903.

Hon. Commissioner of Patents,

Washington, D.C.

Sir:-

I herewith return Letters Patent No. 714,756, granted Dec.2, 1902, to Louis R.Whicher, Alex.P.Browne and Brainerd T.Judkins on the application of John Stone Stone and now owned by the Stone Telegraph and Telephone Company, and request that a certificate of correction be annexed thereto under the provisions of Rule 170, in order to correct the following errors incurred through the fault of the office in printing the specification, to wit:-

In line 83, page 1, change the semi-colon(;) to a period(.) and change "hut" to "But".

In line 91, page 1, change the period(.) to a comma(,) and change "It" to "it".

In line 109, page 5, change "$\frac{1}{C_1 p_2}$" to $\frac{1}{C_1 P^2}$

In line 124, page 5, change the first member of the equation from "$\frac{1}{C_1 P_2}$" to $\frac{1}{C_1 P^2}$

In line 91, page 10, change the dash(-) between the words "non-metallic" and "non-conducting" to a comma(,), cancel the dash (-) between the words "fact" and "dielectric"; and in line 92, page 10, insert a comma(,) between the words "dielectric" and "medium"; so that lines 91 and 92 will read, "non-metallic, non-conducting, in fact dielectric, medium" &c.

This certificate is requested so that the printed specification

Hon.Com.of Pats.....2.

will conform with the specification now on record in the archives of the Patent Office, and because, by reason of the changes in punctuation introduced by the printer, the meaning of certain parts of the specification has been completely changed.

Respectfully,

Alex P. Brown

Attorney for Stone,

Secty & Treas. Stone Tel. & Tel.Co.

Browne, Cl. 2 Q

198161

It is directed that a certificate of correction be endorsed upon Letters Patent No. 714,736, making the changes requested, with the exception that the period in line 91, page 1, should be changed to a semicolon and not to a comma, to conform to the record of the case.

E. B. Moore
Acting Commissioner.

November 25, 1903.

Communications should be addressed to
The Commissioner of Patents,
Washington, D. C.

LETTER No.

DEPARTMENT OF THE INTERIOR.

UNITED STATES PATENT OFFICE,

WASHINGTON, D. C.

In the matter of
Letters Patent No.714,756,
Issued December 2,1902,
John Stone Stone,
Methods of Selective Signaling,
Mr.Alex P.Browne,attorney.

REPORT of the CHIEF of the ISSUE and GAZETTE DIVISION.

The patent is returned calling attention to four departures in the printed specification from the punctuation of the original manuscript,and two errors in the algebraic formulas.

In the matter of punctuation:---

1st In line 85,page 1,the semicolon after the word "systems" should be changed to a period,and the following word "but" should commence with a capital B,making a new sentence,to accord with the copy.

2nd In line 91,page 1,the period after the word "neighborhood" should be changed to a semicolon,(not to a comma as he requests) and the following word "It" should commence with a small i,to conform to the record.

3rd In line 91,page 10,a comma should be substituted for the dash after the word "non-metallic" and the dash after the word "fact" should be stricken out to conform to the copy.

4th In line 92,page 10,a comma should be inserted after the word "dielectric."

In the matter of changed formula:

1st In lines 105-110,page 5,and 2nd In lines 120-125, same page,in the first member of the formula the printer used the inferior "p" instead of the superior L^2,as was evidently intended by the writer of the specification.

straight wire attached freely to the terminal of the coil. These motions are, of course, due to the impact of the molecules, and the irregularity in the distribution of the potential, owing to the roughness and dissymmetry of the wire or filament. With a perfectly symmetrical and polished wire such motions would probably not occur. That the motion is not likely to be due to others causes is evident from the fact that it is not of a definite direction, and that in a very highly exhausted globe it ceases altogether. The possibility of bringing a body to unusual science in an exhausted globe, or even when not at all enclosed, would seem to afford a possible way of obtaining light effects, which, in perfecting methods of producing rapidly alternating potentials, might be rendered available for useful purposes.

In employing a commercial coil, the production of very powerful brush effects is attended with considerable difficulties, for

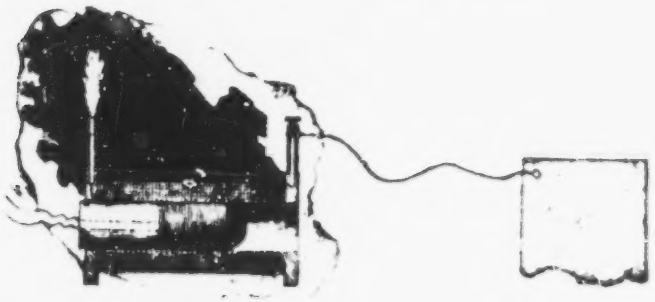

FIG. 1.

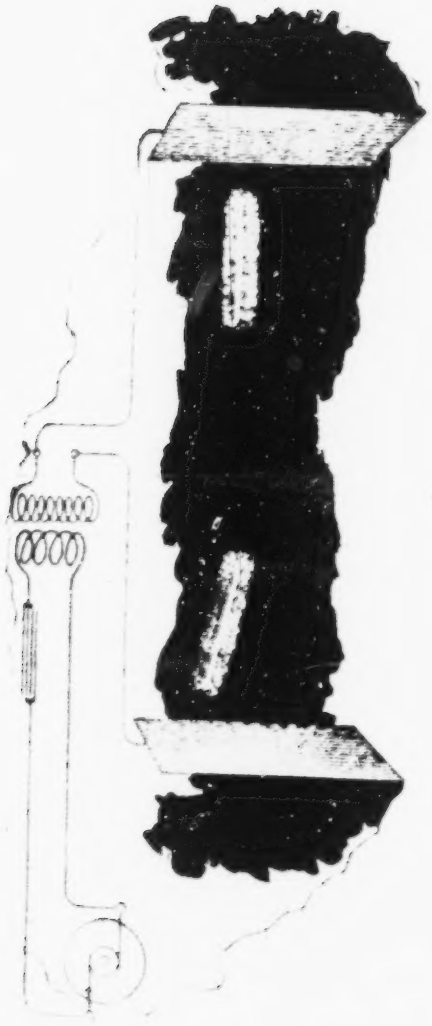
lovable pioneers. Many have been carried away by the enthusiasm and passion to discover, but in their zeal to reach results, some have been misled. Starting with the idea of producing electromagnetic waves, they turned their attention, perhaps, too much to the study of electromagnetic effects, and neglected the study of electrostatic phenomena. Naturally, nearly every investigator availed himself of an apparatus similar to that used in earlier experiments. But in those forms of apparatus, while the electromagnetic inductive effects are enormous, the electrostatic effects are excessively small.

In the Hertz experiments, for instance, a high tension induction coil is short circuited by an arc, the resistance of which is very small, the smaller, the more capacity is attached to the terminals; and the difference of potential at these is enormously diminished. On the other hand, when the discharge is not passing between the terminals, the static effects may be considerable, but only qualitatively so, not quantitatively, since their rise and fall is very sudden, and since their frequency is small. In neither case, therefore, are powerful electrostatic effects perceivable. Similar conditions exist when, as in some interesting experiments of Dr. Lodge, Leyden jars are discharged disruptively. It has been thought — and I believe asserted — that in such cases most of the energy is radiated into space. In the light of the experiments which I have described above, it will now not be thought so. I feel safe in asserting that in such cases most of the energy is partly taken up and converted into heat in the arc of the discharge and in the conducting and insulating material of the jar, some energy being, of course, given off by electrification of the air, but the amount of the directly radiated energy is very small.

When a high tension induction coil, operated by currents alternating only 20,000 times a second, has its terminals closed through even a very small jar, practically all the energy passes through the dielectric of the jar, which is heated, and the electrostatic effects manifest themselves outwardly only to a very weak degree. Now the external circuit of a Leyden jar, that is, the arc and the connections of the coatings, may be looked upon as a circuit containing alternating currents of excessively high frequency and fairly high potential, which are passed through the coatings and the dielectric between them, and there, for about the reasons that the external electrostatic effects cannot be very considerable,



385229

...generally speaking, of any considered apparatus, but low frequencies can be resorted to, recourse must, therefore, be had to some other means. The discharge of a condenser affords us a means of obtaining frequencies by far higher than are obtainable mechanically, and I have accordingly employed condensers in my experiments to the above end.

When the terminals of a high tension induction coil, Fig. 126, are connected to a Leyden jar, and the latter is discharging disruptively into a circuit, we may look upon the arc playing between the knobs as being a source of alternating, or generally speaking, undulating currents, and then we have to deal with the familiar system of a generator of such currents, a circuit connected to it, and a condenser bridging the circuit. The condenser in such case is a veritable transformer, and since the frequency is excessive, almost any ratio in the strength of the currents in both the branches may be obtained. In reality the analogy is not quite complete, for in the disruptive discharge we have most generally a fundamental instantaneous variation of comparatively low frequency, and a superimposed harmonic vibration, and the laws governing the flow of currents are not the same for both.

In converting in this manner, the ratio of conversion should not be too great, for the loss in the arc between the knobs increases with the square of the current, and if the jar be discharged through very thick and short conductors, with the view of obtaining a very rapid oscillation, a very considerable portion of the energy stored is lost. On the other hand, too small ratios are not practicable for many obvious reasons.

As the converted currents flow in a practically closed circuit, the electrostatic effects are necessarily small, and I therefore convert them into currents or effects of the required character. I have effected such conversions in several ways. The preferred plan of connections is illustrated in Fig. 127. The manner of operating renders it easy to obtain by means of a small and inexpensive apparatus enormous differences of potential which have been usually obtained by means of large and expensive coils. For this it is only necessary to take an ordinary small coil, adjust to it a condenser and discharging circuit, forming the primary of an auxiliary small coil, and convert upward. As the inductive effect of the primary currents is excessively great, the second coil need have comparatively but very few turns. By properly adjusting the elements, remarkable results may be secured.

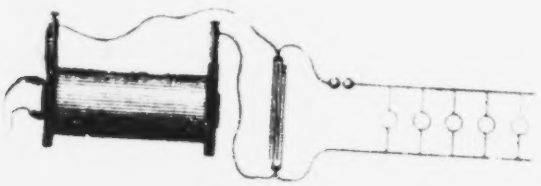


FIG 126

introduction on an industrial scale. Now that all modern research seems to point with certainty to the use of electricity of excessively high tension, the question must present itself to many whether it is not possible to obtain in a practicable manner this form of energy from heat. We have been used to look upon an electrostatic machine as a plaything, and somehow we couple with it the idea of the inefficient and impractical. But now we must think differently, for now we know that everywhere we have to deal with the same forces, and that it is a mere question of inventing proper methods or apparatus for rendering them available.

In the present systems of electrical distribution, the employment of the iron with its wonderful magnetic properties allows us to reduce considerably the size of the apparatus; but, in spite of this, it is still very cumbersome. The more we progress in the study of electric and magnetic phenomena, the more we be-

come convinced that the present methods will be short-lived. For the production of light, at least, such heavy machinery would seem to be unnecessary. The energy required is very small, and if light can be obtained as efficiently as, theoretically, it appears possible, the apparatus need have but a very small output. There being a strong probability that the illuminating methods of the future will involve the use of very high potentials, it seems very desirable to perfect a contrivance capable of converting the energy of heat into energy of the requisite form. Nothing to speak of has been done towards this end, for the thought that electricity of some 50,000 or 100,000 volts pressure or more, even if obtained, would be unavailable for practical purposes, has deterred inventors from working in this direction.

In Fig. 126 a plan of connections is shown for converting currents of high, into currents of low, tension by means of the disruptive discharge of a condenser. This plan has been used by

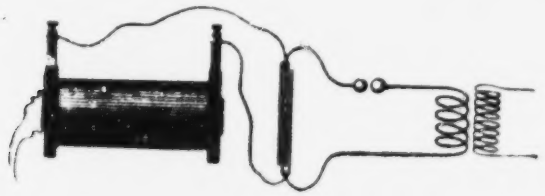

FIG. 127.

me frequently for operating a few incandescent lamps required in the laboratory. Some difficulties have been encountered in the arc of the discharge which I have been able to overcome to a great extent; besides this, and the adjustment necessary for the proper working, no other difficulties have been met with, and it was easy to operate ordinary lamps, and even motors, in this manner. The line being connected to the ground, all the wires could be handled with perfect impunity, no matter how high the potential at the terminals of the condenser. In these experiments a high tension induction coil, operated from a battery or from an alternate current machine, was employed to charge the condenser; but the induction coil might be replaced by an apparatus of a different kind, capable of giving electricity of such high tension. In this manner, direct or alternating currents may be converted, and in both cases the current-impulses may be of any desired frequency. When the currents charging the condenser are of the

3396

interrupter or break, or by the use of an alternator. Earlier English investigators to mention only Spottiswoode and J. E. H. Gordon, have used a rapid break in connection with the coil. Our knowledge and experience of to-day enables us to see clearly why these coils under the conditions of the test did not disclose any remarkable phenomena, and why able experimenters failed to perceive many of the curious effects which have since been observed.

In the experiments such as performed this evening, we operate the coil either from a specially constructed alternator capable of giving many thousands of reversals of current per second, or, by disruptively discharging a condenser through the primary, we set up a vibration in the secondary circuit of a frequency of many hundred thousand or millions per second, if we so desire; and in using either of these means we enter a field as yet unexplored.

It is impossible to pursue an investigation in any novel line without finally making some interesting observation or learning some useful fact. That this statement is applicable to the subject of this lecture the many curious and unexpected phenomena which we observe afford a convincing proof. By way of illustration, take for instance the most obvious phenomena, those of the discharge of the induction coil.

Here is a coil which is operated by currents vibrating with extreme rapidity, obtained by disruptively discharging a Leyden jar. It would not surprise a student were the lecturer to say that the secondary of this coil consists of a small length of comparatively stout wire; it would not surprise him were the lecturer to state that, in spite of this, the coil is capable of giving any potential which the best insulation of the turns is able to withstand; but although he may be prepared, and even be indifferent as to the anticipated result, yet the aspect of the discharge of the coil will surprise and interest him. Every one is familiar with the discharge of an ordinary coil; it need not be reproduced here. But, by way of contrast, here is a form of discharge of a coil, the primary current of which is vibrating several hundred thousand times per second. The discharge of an ordinary coil appears as a simple line or band of light. The discharge of this coil appears in the form of powerful brushes and luminous streams issuing from all points of the two straight wires attached to the terminals of the secondary. (Fig. 130.)

Now compare this phenomenon which you have just witnessed

with the discharge of a Holtz or Wimshurst machine—that other interesting appliance so dear to the experimenter. What a difference there is between these phenomena! And yet, had I made the necessary arrangements—which could have been made easily, were it not that they would interfere with other experiments—I could have produced with this coil sparks which, had I the coil

FIG. 130

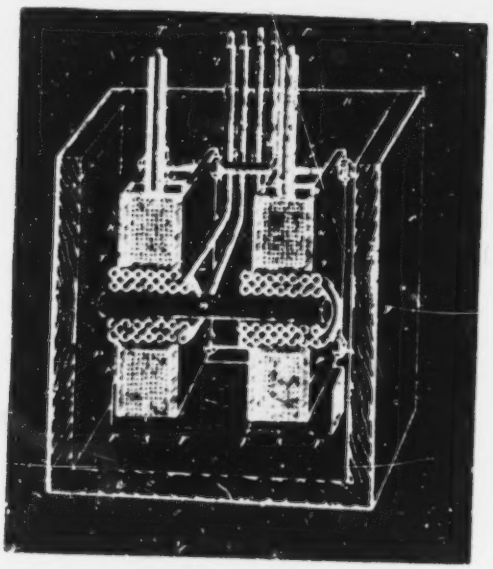
FIG. 131

hidden from your view and only two knobs exposed, even the keenest observer among you would find it difficult, if not impossible, to distinguish from those of an influence or friction machine. This may be done in many ways—for instance, by operating the induction coil which charges the condenser from an alternating-current machine of very low frequency, and preferably adjusting the discharge circuit so that there are no oscillations set up in it. We then obtain in the secondary circuit, if the knobs are of the required size and properly set, a more or less

as, to produce each phenomenon at its best, a very careful adjustment is required. But even if imperfectly produced, as they are likely to be this evening, they are sufficiently striking to interest an intelligent audience.

Before showing some of these curious effects I must, for the sake of completeness, give a short description of the coil and other apparatus used in the experiments with the disruptive discharge this evening.

It is contained in a box *a* (Fig. 132) of thick boards of hard



wood, covered on the outside with a sheet of copper carefully soldered all around. It might be advisable, in accurate investigation, where accuracy is of great importance, to dispense with the metal cover, as it might introduce disturbances, principally on account of its complex action upon the coil and the device of very small capacity and considerable self-induction magneto-circuit. When the conditions [illegible] are here considered, the employment of a copper cover offers some practical advantage, and there are certain [illegible] to be dealt upon.

The coil should be placed [illegible]

and the space between should, of course, not be too small, certainly not less than, say, five centimetres, but much more if possible; especially the two sides of the zinc box, which are at right angles to the axis of the coil, should be sufficiently remote from the latter, as otherwise they might impair its action and be a source of loss.

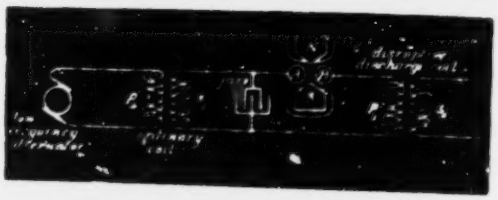
The coil consists of two spools of hard rubber *r, r*, held apart at a distance of 10 centimetres by bolts *c* and nuts *n*, likewise of hard rubber. Each spool comprises a tube *t* of approximately 8 centimetres inside diameter, and 3 millimetres thick, upon which are screwed two flanges *r, r*, 24 centimetres square, the space between the flanges being about 3 centimetres. The secondary, *s s*, of the best gutta percha-covered wire, has 26 layers, 10 turns in each, giving for each half a total of 260 turns. The two halves are wound oppositely and connected in series, the connection between both being made over the primary. This disposition, besides being convenient, has the advantage that when the coil is well balanced—that is, when both of its terminals *t, t*, are connected to bodies or devices of equal capacity—there is not much danger of breaking through to the primary, and the insulation between the primary and the secondary need not be thick. In using the coil it is advisable to attach to *both* terminals devices of nearly equal capacity, as, when the capacity of the terminals is not equal, sparks will be apt to pass to the primary. To avoid this, the middle point of the secondary may be connected to the primary, but this is not always practicable.

The primary *p p* is wound in two parts, and oppositely, upon a wooden spool *w*, and the four ends are led out of the oil through hard rubber tubes *l l*. The ends of the secondary *s, s*, are also led out of the oil through rubber tubes *l, l*, of great thickness. The primary and secondary layers are insulated by cotton cloth, the thickness of the insulation, of course, bearing some proportion to the difference of potential between the turns of the different layers. Each half of the primary has four layers, 24 turns in each, thus giving a total of 96 turns. When both the parts are connected in series, this gives a ratio of conversion of about 1 : 2·7, and with the primaries in multiple, 1 : 5·4; but in operating with very rapidly alternating currents this ratio does not convey even an approximate idea of the ratio of the E. M. F's. in the primary and secondary circuits. The coil is held in position in the oil on wooden supports, there being about 3 centimetres

In another arrangement with the magnet I take the discharge between the rounded pole pieces themselves, which in this case are insulated and preferably provided with polished brass caps.

The employment of an intense magnetic field is of advantage principally when the inductorium coil or transformer which charges the condenser is operated by currents of very low frequency. In such a case the number of the fundamental discharges between the knobs may be so small as to render the currents produced in the secondary unsuitable for many experiments. The intense magnetic field then serves to blow out the arc between the knobs as soon as it is formed, and the fundamental discharges occur in quicker succession.

Instead of the magnet, a draught or blast of air may be employed with some advantage. In this case the arc is preferably



established between the knobs a b, as in Fig. 1(a) of the knobs c d being generally joined, or entirely done away with, as in the disposition the arc is long and unsteady, and is easily affected by the draught.

When a magnet is employed to break the arc, it is better to choose the connections indicated diagrammatically in Fig. 1(b) as in this case the currents forming the arc are much more powerful, and the magnetic field exercises a greater influence. The use of the magnet permits, however, of the arc being replaced by a vacuum tube, but I have encountered great difficulties in working with an exhausted tube.

The other form of discharger used in these and similar experiments is indicated in Figs. 1(c) and 1(d). It consists of a number of brass pieces, as in Fig. 1(c), each of which comprises a spherical middle portion a with two extensions b c, which is merely used to fasten the piece in a lathe when polishing up the discharging

...and a column above, which consists of a knurled flange ... surmounted by a threaded stem *l* carrying a nut *n*, by means ... which a wire is fastened to the column. The flange *f* conveniently serves for holding the brass piece when fastening the

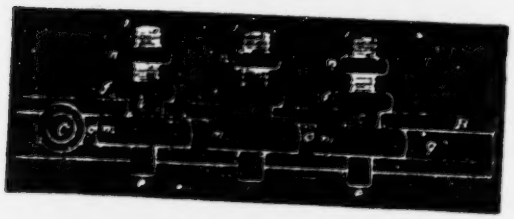


FIG. 135.

...and also for turning it in any position when it becomes ...essary to present a fresh discharging surface. Two stout ...ips of hard rubber *r r*, with planed grooves *q q* (Fig. 136) to fit ...e middle portion of the pieces *c c*, serve to clamp the latter ...nd hold them firmly in position by means of two bolts *c c* ...of which only one is shown) passing through the ends of the ...rips.

In the use of this kind of discharger I have found three principal advantages over the ordinary form. First, the dielectric ...trength of a given total width of air space is greater when a ...great many small air gaps are used instead of one, which permits

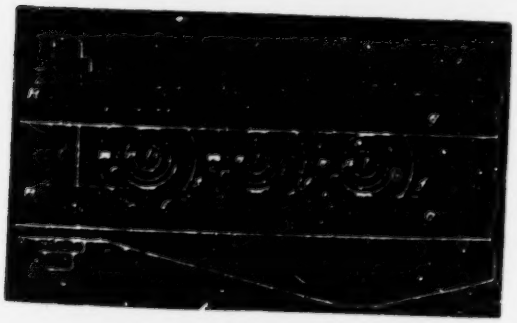

FIG. 136.

...working with a smaller length of air gap, and that means ...smaller loss and less deterioration of the metal; secondly, by ...means of splitting the arc up into smaller arcs, the polished ...faces are made to last much longer; and, thirdly, the appe...

3402

ratus affords some gauge to the experiments. I usually set the pieces by putting between them sheets of mica for the known certain very small distance which is known from the experiments of Sir William Thomson to require a certain electromotive force to be bridged by the spark.

It should, of course, be remembered that the sparking distance is much diminished as the frequency is increased. By taking any number of sparks the experimenter has a rough idea of the electromotive force, and he finds it easier to repeat an experiment, as he has not the trouble of setting the knobs again and again. With this kind of discharger I have been able to maintain an oscillating motion without any spark being visible with the naked eye between the knobs, and they would not show a very appreciable rise of temperature. This form of discharger also lends itself to many arrangements of condensers and circuits which are often very convenient and time saving. I have used it preferably in a disposition similar to that indicated in Fig. 131, when the currents forming the arc are small.

I may here mention that I have also used dischargers with single or multiple air gaps, in which the discharge surfaces were rotated with great speed. No particular advantage was, however, gained by this method, except in cases where the currents from the condenser were large and the keeping cool of the surfaces was necessary, and in cases when the discharge not being oscillating of itself, the arc as soon as established was broken by the movement, thus starting the vibrations at intervals in rapid succession. I have also used mechanical interrupters in many ways. To avoid the difficulties with frictional contacts the general plan adopted was to establish the arc and create through it at great speed a current pulse produced by many independent metal plates. It is understood, of course, that the employment of an engine's armature or other interrupter presents no effect worth noticing, unless the self-induction is small and resistance [illegible] that the [illegible] and speed such interrupters.

I will now refer to [illegible]

[illegible]

some experiments, and many times convenient for the purposes of adjustment, I cover the secondary with wax, and turn it off in a lathe to a diameter slightly smaller than the inside of the primary coil. The latter I provide with a handle reaching out of the oil, which serves to shift it in any position along the secondary.

I will now venture to make, in regard to the general manipulation of induction coils, a few observations bearing upon points which have not been fully appreciated in earlier experiments with such coils, and are even now often overlooked.

The secondary of the coil possesses usually such a high self-induction that the current through the wire is inappreciable, and may be so even when the terminals are joined by a conductor of small resistance. If capacity is added to the terminals, the self-induction is counteracted, and a stronger current is made to flow through the secondary, though its terminals are insulated from each other. To one entirely unacquainted with the properties of alternating currents nothing will look more puzzling. This feature was illustrated in the experiment performed at the beginning with the top plates of wire gauze attached to the terminals and the rubber plate. When the plates of wire gauze were close together, and a small arc passed between them, the arc *prevented* a strong current from passing through the secondary, because it did away with the capacity on the terminals; when the rubber plate was inserted between, the capacity of the condenser formed counteracted the self-induction of the secondary, a stronger current passed now, the coil performed more work, and the discharge was by far more powerful.

The first thing, then, in operating the induction coil is to combine capacity with the secondary to overcome the self-induction. If the frequencies and potentials are very high, gaseous matter should be carefully kept away from the charged surfaces. If Leyden jars are used, they should be immersed in oil, as otherwise considerable dissipation may occur if the jars are greatly strained. When high frequencies are used, it is of equal importance to combine a condenser with the primary. One may use a condenser connected to the ends of the primary or to the terminals of the alternator, but the latter is not to be recommended, as the machine might be injured. The best way is undoubtedly to use the condenser in series with the primary and with the alternator, and to adjust its capacity so as to annul the

self-induction of both the latter. The condenser should be adjustable by very small steps, and for a fine adjustment a small air condenser with movable plates may be used conveniently.

I think it best at this juncture to bring before you a phenomenon observed by me some time ago, which to the patient scientific investigator may perhaps appear more interesting than any of the results which I have the privilege to present to you this evening.

It may be quite properly ranked among the brush phenomena, in fact, it is a brush, formed at, or near, a single terminal of high potential.

In bulbs provided with a conducting terminal, though it be of

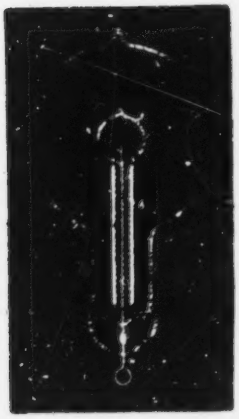

FIG. 141

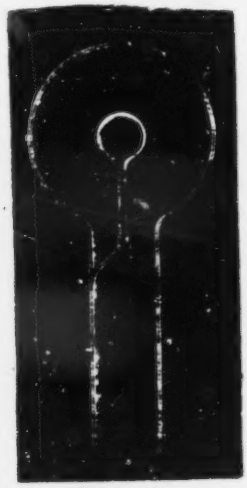

FIG. 142

aluminum, the brush has but an ephemeral existence, and cannot, unfortunately, be indefinitely preserved in its most sensitive state, even in a bulb devoid of any conducting electrode. In studying the phenomenon, by all means a bulb having a leading-in wire should be used. I have found it best to use bulbs constructed as indicated in Figs. 141 and 142.

In Fig. 141 the bulb comprises an incandescent lamp globe *f* in the neck of which is sealed a barometer tube *b*, the end of which is blown out to form a small sphere *s*. This sphere should be sealed as closely as possible in the centre of the large globe. Before sealing, a thin tube *t*, of aluminum sheet, may be slipped on the barometer tube, but it is not important to employ it.

I have been unable to produce the phenomenon with the disruptive discharge coil, although every other of these phenomena can be well produced by it—many, in fact, much better than with coils operated from an alternator.

It may be possible to produce the brush by impulses of one direction, or even by a steady potential, in which case it would be still more sensitive to magnetic influence.

In operating an induction coil with rapidly alternating currents, we realize with astonishment, for the first time, the great importance of the relation of capacity, self-induction and frequency as regards the general results. The effects of capacity are the most striking, for in these experiments, since the self-induction and frequency both are high, the critical capacity is very small, and need be but slightly varied to produce a very considerable change. The experimenter may bring his body in contact with the terminals of the secondary of the coil, or attach to one or both terminals insulated bodies of very small bulk, such as bulbs, and he may produce a considerable rise or fall of potential, and greatly affect the flow of the current through the primary. In the experiment before shown, in which a brush appears at a wire attached to one terminal, and the wire is vibrated when the experimenter brings his insulated body in contact with the other terminal of the coil, the sudden rise of potential was made evident.

I may show you the behavior of the coil in another manner which possesses a feature of some interest. I have here a little light fan of aluminum sheet, fastened to a needle and arranged to rotate freely in a metal piece screwed to one of the terminals of the coil. When the coil is set to work, the molecules of the air are rhythmically attracted and repelled. As the force with which they are repelled is greater than that with which they are attracted, it results that there is a repulsion exerted on the surfaces of the fan. If the fan were made simply of a metal sheet, the repulsion would be equal on the opposite sides, and would produce no effect. But if one of the opposing surfaces is screened, or if, generally speaking, the bombardment on this side is weakened in some way or other, there remains the repulsion exerted upon the other, and the fan is set in rotation. The screening is best effected by fastening upon one of the opposing sides of the fan insulated conducting coatings, or, if the fan is made in the shape of an ordinary propeller screw, by fastening on one

3407

show you is that this motor rotates with *one single* connection between it and the generator; that is to say, one terminal of the motor is connected to one terminal of the generator—in this case the secondary of a high-tension induction coil—the other terminals of motor and generator being insulated in space. To produce rotation it is generally (but not absolutely) necessary to connect the free end of the motor coil to an insulated body of some size. The experimenter's body is more than sufficient. If he touches the free terminal with an object held in the hand, a current passes through the coil and the copper disc is set in rotation. If an exhausted tube is put in series with the coil, the tube lights brilliantly, showing the passage of a strong current. In-

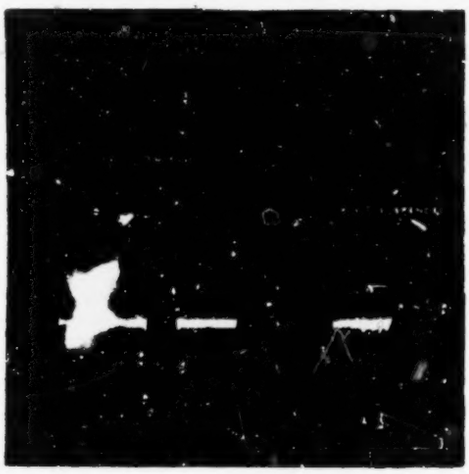

FIG. 146.

stead of the experimenter's body, a small metal sheet suspended on a cord may be used with the same result. In this case the plate acts as a condenser in series with the coil. It counteracts the self-induction of the latter and allows a strong current to pass. In such a combination, the greater the self-induction of the coil the smaller need be the plate, and this means that a lower frequency, or eventually a lower potential, is required to operate the motor. A single coil wound upon a core has a high self-induction; for this reason, principally, this type of motor was chosen to perform the experiment. Were a secondary closed coil wound upon the core, it would tend to diminish the self-

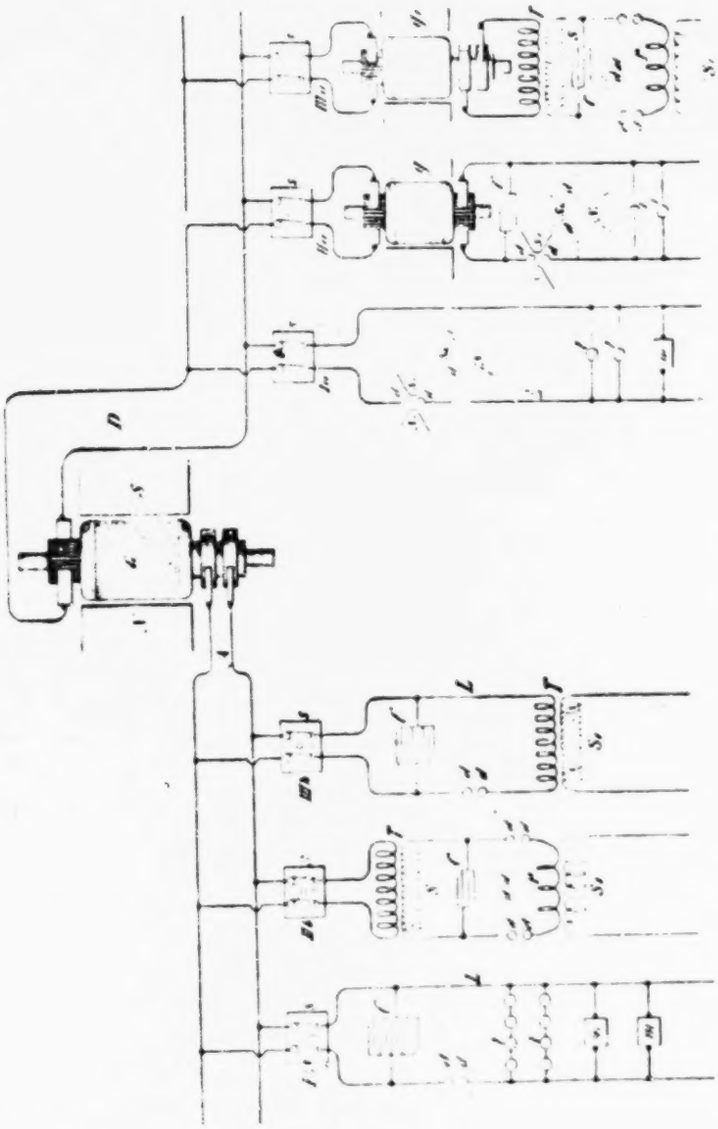

FIG. 165.

3409

plan is to charge condensers, from a direct or alternate current source, preferably of high tension, and to discharge them disruptively while observing well-known conditions necessary to maintain the oscillations of the current. In view of the general interest taken in high-frequency currents and effects producible by them, it seems to me advisable to dwell at some length upon this method of conversion. In order to give you a clear idea of the action, I will suppose that a continuous-current generator is employed, which is often very convenient. It is desirable that the generator should possess such high tension as to be able to break through a small air space. If this is not the case, then auxiliary means have to be resorted to, some of which will be indicated subsequently. When the condensers are charged to a certain potential, the air, or insulating space, gives way and a disruptive discharge occurs. There is then a sudden rush of current and generally a large portion of accumulated electrical energy spends itself. The condensers are thereupon quickly charged and the same process is repeated in more or less rapid succession. To produce such sudden rushes of current it is necessary to observe certain conditions. If the rate at which the condensers are discharged is the same as that at which they are charged, then, clearly, in the assumed case the condensers do not come into play. If the rate of discharge be smaller than the rate of charging, then, again, the condensers cannot play an important part. But if, on the contrary, the rate of discharging is greater than that of charging, then a succession of rushes of current is obtained. It is evident that, if the rate at which the energy is dissipated by the discharge is very much greater than the rate of supply to the condensers, the sudden rushes will be comparatively few, with long-time intervals between. This always occurs when a condenser of considerable capacity is charged by means of a comparatively small machine. If the rates of supply and dissipation are not widely different, then the rushes of current will be in quicker succession, and this the more, the more nearly equal both the rates are, until limitations incident to each case and depending upon a number of causes are reached. Thus we are able to obtain from a continuous-current generator as rapid a succession of discharges as we like. Of course, the higher the tension of the generator, the smaller need be the capacity of the condensers, and for this reason, principally, it is of advantage to employ a generator of very high tension. Besides, such a generator permits the attaining of greater rates of vibration.

The impulses of current may be of the same direction under the conditions before assumed, but most generally there is an oscillation superimposed upon the fundamental vibration of the current. When the conditions are so determined that there are no oscillations, the current impulses are unidirectional and thus a means is provided of transforming a continuous current of high tension, into a direct current of lower tension, which I think may find employment in the arts.

This method of conversion is exceedingly interesting and I was much impressed by its beauty when I first conceived it. It is ideal in certain respects. It involves the employment of no mechanical devices of any kind, and it allows of obtaining currents of any desired frequency from an ordinary circuit, direct or alternating. The frequency of the fundamental discharges depending on the relative rates of supply and dissipation can be readily varied within wide limits, by simple adjustments of these quantities, and the frequency of the superimposed vibration by the adjustment of the capacity, self-induction and resistance of the circuit. The potential of the currents, again, may be raised as high as any insulation is capable of withstanding safely by combining capacity and self induction or by induction in a secondary, which need have but comparatively few turns.

As the conditions are often such that the intermittence or oscillation does not readily establish itself, especially when a direct current source is employed, it is of advantage to associate an interrupter with the arc, as I have, some time ago, indicated the use of an air-blast or magnet, or other such device readily at hand. The magnet is employed with special advantage in the conversion of direct currents, as it is then very effective. If the primary source is an alternate current generator, it is desirable, as I have stated on another occasion, that the frequency should be low, and that the current forming the arc be large, in order to render the magnet more effective.

A form of such discharger with a magnet which has been found convenient, and adopted after some trials, in the conversion of direct currents particularly, is illustrated in Fig. 168. s s are the pole pieces of a very strong magnet which is excited by a coil c. The pole pieces are slotted for adjustment and can be fastened in any position by screws s_1 s_1. The discharge rods d d_1, thinned down on the ends in order to allow a closer approach of the magnetic pole pieces, pass through the columns of brass b b_1 and are fastened in position by screws s_2 s_2. Springs r r_1 and collars c c_1

are slipped on the rods, the latter serving to set the points of the rods at a certain suitable distance by means of screws s_1 s_2 and the former to draw the points apart. When it is desired to start the arc, one of the large rubber handles h h_1 is tapped quickly with the hand, whereby the points of the rods are brought in contact but are instantly separated by the springs r r_1. Such an arrangement has been found to be often necessary, namely in cases when the E. M. F. was not large enough to cause the discharge to break through the gap, and also when it was desirable to avoid short circuiting of the generator by the metallic contact of the rods. The rapidity of the interruptions of the current with a magnet depends on the intensity of the magnetic field and on the

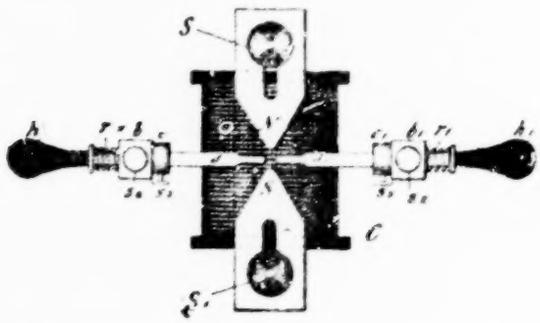

FIG. 166.

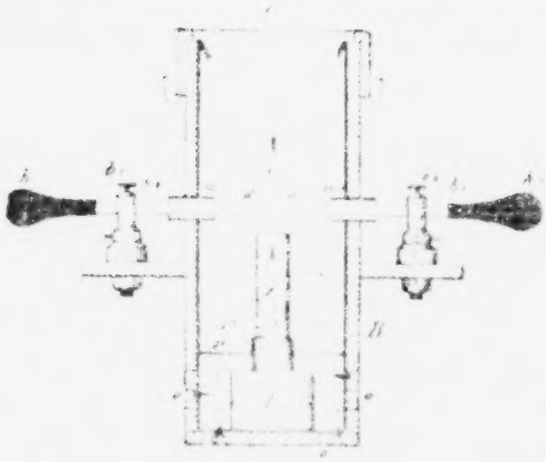
potential difference at the end of the arc. The interruptions are generally in such quick succession as to produce a musical sound. Years ago it was observed that when a powerful induction coil is discharged between the poles of a strong magnet, the discharge produces a loud noise not unlike a small pistol shot. It was vaguely stated that the spark was intensified by the presence of the magnetic field. It is now clear that the discharge current, flowing for some time, was interrupted a great number of times by the magnet, thus producing the sound. The phenomenon is especially marked when the field circuit of a large magnet or dynamo is broken in a powerful magnetic field.



It is desirable to exclude the light as perfectly as possible, as it interferes with some experiments. The form of discharger is simple and very effective when properly manipulated. The air being warmed to a certain temperature, has its insulating power impaired; it becomes dielectrically weak, as it were, and the consequence is that the arc can be established at much greater distance. The arc should, of course, be sufficiently insulating to allow the discharge to pass through the gap *downstream*. The arcs formed under such conditions, when long, may be made extremely sensitive, and the weak draught through the lamp chimney *c* is quite sufficient to produce rapid interruptions. The adjustment is made by regulating the temperature and velocity of the draught. Instead of using the lamp, it answers the purpose to provide for a draught of warm air in other way. A very simple way which has been practiced is to enclose the arc in a long vertical tube, with plates on the top and bottom for regulating the temperature and velocity of the air current. Some provision had to be made for deadening the sound.

The air may be rendered dielectrically weak also by convection. Dischargers of this kind have likewise been used by me in connection with a magnet. A large tube is for this purpose provided with heavy electrodes of carbon or metal, between which the discharge is made to pass, the tube being placed in a powerful magnetic field. The exhaustion of the tube is carried to a point at which the discharge breaks through easily, but the pressure should be more than 76 millimetres, at which the ordinary thread discharge occurs. In another form of discharger, combining the features before mentioned, the discharge was made to pass between two adjustable magnetic pole pieces, the space between them being kept at an elevated temperature.

It should be remarked here that when such, or interrupting devices of any kind, are used and the currents are passed through the primary of a disruptive discharge coil, it is not, as a rule, of advantage to produce a number of interruptions of the current per second greater than the natural frequency of vibration of the dynamo supplying the current, when such is used. It cannot be pointed out in full that while the devices mentioned in connection with the disruptive discharge are advantageous under certain conditions, they may be sometimes a source of trouble as they produce disturbances of other irregularities in the operation which it would be very desirable to overcome.

3414

There is, I regret to say, in this beautiful method of conversion a defect, which fortunately is not vital, and which I have been gradually overcoming. I will best call attention to this defect and indicate a fruitful line of work, by comparing the electrical process with its mechanical analogue. The process may be illustrated in this manner. Imagine a tank with a wide opening at the bottom, which is kept closed by spring pressure, but so that it snaps off *suddenly* when the liquid in the tank has reached a certain height. Let the fluid be supplied to the tank by means of a pipe feeding at a certain rate. When the critical height of the liquid is reached, the spring gives way and the bottom of the tank drops out. Instantly the liquid falls through the wide opening, and the spring, reasserting itself, closes the bottom again. The tank is now filled, and after a certain time interval the same process is repeated. It is clear, that if the pipe feeds the fluid quicker than the bottom outlet is capable of letting it pass through, the bottom will remain off and the tank will still overflow. If the rate of supply are exactly equal, then the bottom lid will remain partially open and no vibration of the same and of the liquid column will generally occur, though it might, if started by some means. But if the inlet pipe does not feed the fluid fast enough for the outlet, then there will be always vibration. Again, in such case, each time the bottom flaps up or down, the spring and the liquid column, if the pliability of the spring and the inertia of the moving parts are properly chosen, will perform [illegible] vibrations. In the analogue the fluid may be likened to electricity or electrical energy, the tank to the condenser, the spring to the dielectric, and the pipe to the conductor through which electricity is supplied to the condenser. To make this analogy quite complete it is necessary to make the assumption that the bottom, each time it gives way, is knocked or lightly struck by a hammer, to stop the impact involving some loss of energy, and that is, also, some dissipation of energy results due to frictional losses. In the passage through the liquid it is supposed to be under steady pressure. If the pressure of the liquid be assumed to vary rhythmically, [illegible] [illegible] [illegible]

As regards the latter, which in the electrical analogue corresponds to the losses due to the resistance of the circuits, it is impossible to obviate them entirely, but they can be reduced to a minimum by a proper selection of the dimensions of the circuits and by the employment of thin conductors in the form of strands. But the loss of energy caused by the first breaking through of the dielectric—which in the above example corresponds to the violent knock of the bottom against the inelastic stop—would be more important to overcome. At the moment of the breaking through the air space has a very high resistance, which is probably reduced to a very small value when the current has reached some strength, and the space is brought to a high temperature. It would materially diminish the loss of energy if the space were always kept at an extremely high temperature, but then there would be no disruptive break. By warming the space moderately by means of a lamp or otherwise, the economy as far as the arc is concerned is sensibly increased. But the magnet or other interrupting device does not diminish the loss in the arc. Likewise, a jet of air only facilitates the carrying off of the energy. Air, or a gas in general, behaves curiously in this respect. When two bodies charged to a very high potential discharge disruptively through an air space, any amount of energy may be carried off by the air. This energy is evidently dissipated by bodily carriers, in impact and collisional losses of the molecules. The exchange of the molecules in the space occurs with inconceivable rapidity. A powerful discharge taking place between two electrodes, they may remain entirely cool, and yet the loss in the air may represent any amount of energy. It is perfectly practicable, with very great potential differences in the gap, to dissipate several horse power in the arc of the discharge without even noticing a small increase in the temperature of the electrodes. All the frictional losses occur then practically in the air. If the exchange of the air molecules is prevented, as by enclosing the gap hermetically, the gas inside of the vessel is brought quickly to a high temperature, even with a very small discharge. It is difficult to estimate how much of the energy is lost in sound waves, audible or not, in a powerful discharge. When the currents through the gap are large, the electrodes may become rapidly heated, but this is not a reliable measure of the energy wasted in the arc, as the loss through the gas itself may be comparatively small. The air or a gas in general is, at ordinary pressure at least

clearly not the best medium through which a disruptive discharge should occur. Air or other gas under great pressure is of course a much more suitable medium for the discharge gap. I have carried on long-continued experiments in this direction, unfortunately less practicable on account of the difficulties and expense in getting air under great pressure. But even if the medium in the discharge space is solid or liquid, still the same losses take place, though they are generally smaller, for just as soon as the arc is established, the solid or liquid is volatilized. Indeed, there is no body known which would not be disintegrated by the arc, and it is an open question among scientific men, whether an arc discharge could occur at all in the air itself without the particles of the electrodes being torn off. When the current through the gap is very small and the arc very long, I believe that a relatively considerable amount of heat is taken up in the disintegration of the electrodes, which partially on this account may remain quite cold.

The ideal medium for a discharge gap should only *crack*, and the ideal electrode should be of some material which cannot be disintegrated. With small currents through the gap it is best to employ aluminum, but not when the currents are large. The disruptive break in the air, or more or less in any ordinary medium, is not of the nature of a crack, but it is rather comparable to the piercing of innumerable bullets through a mass offering great frictional resistances to the motion of the bullets, this involving considerable loss of energy. A medium which would merely crack when strained electrostatically—and this possibly might be the case with a perfect vacuum, that is, pure ether—would involve a very small loss in the gap, so small as to be entirely negligible, at least theoretically, because a crack may be produced by an infinitely small displacement. In exhausting an oblong bulb provided with two aluminum terminals, with the greatest care, I have succeeded in producing such a vacuum that the secondary discharge of a disruptive discharge coil would break disruptively through the bulb in the form of fine spark streams. The curious point was that the discharge would completely ignore the terminals and start far behind the two aluminum plates which served as electrodes. This extraordinary high vacuum could only be maintained for a very short while. To return to the ideal medium, think, for the sake of illustration, of a piece of glass or similar body clamped in a vice, and the latter tightened more and

more. At a certain point a minute increase of the pressure will cause the glass to crack. The loss of energy involved in splitting the glass may be practically nothing, for though the force is great, the displacement need be but extremely small. Now imagine that the glass would possess the property of closing again perfectly the crack upon a minute diminution of the pressure. This is the way the dielectric in the discharge space should behave. But inasmuch as there would be always some loss in the gap, the medium, which should be continuous, should exchange through the gap at a rapid rate. In the preceding example, the glass being perfectly closed, it would mean that the dielectric in the discharge space possesses a great insulating power; the glass being cracked, it would signify that the medium in the space is a good conductor. The dielectric should vary enormously in resistance by minute variations of the E. M. F. across the discharge space. This condition is attained, but in an extremely imperfect manner, by warming the air space to a certain critical temperature, dependent on the E. M. F. across the gap, or by otherwise impairing the insulating power of the air. But as a matter of fact the air does never break down *disruptively*, if this term be rigorously interpreted, for before the sudden rush of the current occurs, there is always a weak current preceding it, which rises first gradually and then with comparative suddenness. That is the reason why the rate of change is very much greater when glass, for instance, is broken through, than when the break takes place through an air space of equivalent dielectric strength. As a medium for the discharge space, a solid, or even a liquid, would be preferable therefor. It is somewhat difficult to conceive of a solid body which would possess the property of closing instantly after it has been cracked. But a liquid, especially under great pressure, behaves practically like a solid, while it possesses the property of closing the crack. Hence it was thought that a liquid insulator might be more suitable as a dielectric than air. Following out this idea, a number of different forms of dischargers in which a variety of such insulators, sometimes under great pressure, were employed, have been experimented upon. It is thought sufficient to dwell in a few words upon one of the forms experimented upon. One of these dischargers is illustrated in Figs. 168*a* and 168*b*.

A hollow metal pulley P (Fig. 168*a*), was fastened upon an arbor *a*, which by suitable means was rotated at a considerable

speed. On the inside of the pulley, but disconnected from the same, was supported a thin disc *h* (which is shown thick for the sake of clearness), of hard rubber in which there were embedded two metal segments *s s* with metallic extensions *e e* into which were screwed conducting terminals *t t* covered with thick tubes of hard rubber *t t*. The rubber disc *h* with its metallic segments *s s*, was finished in a lathe, and its entire surface highly polished so as to offer the smallest possible frictional resistance to the motion through a fluid. In the hollow of the pulley an insulating liquid such as a thin oil was poured so as to reach very nearly to the opening left in the flange *f*, which was screwed tightly on the front side of the pulley. The terminals *t t*, were connected to the opposite coatings of a battery of condensers so that the discharge occurred through the liquid. When the pulley was rotated, the liquid was forced against the rim of the pulley and considerable fluid pressure resulted. In this simple way the discharge gap

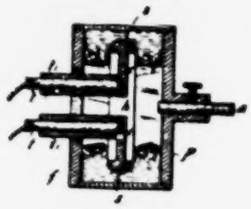


FIG. 168a.

FIG. 168b

was filled with a medium which behaved practically like a solid, which possessed the quality of closing instantly upon the occurrence of the break, and which moreover was circulating through the gap at a rapid rate. Very powerful effects were produced by discharges of this kind with liquid interrupters, of which a number of different forms were made. It was found that, as expected, a longer spark for a given length of wire was obtainable in this way than by using air as an interrupting device. Generally the speed, and therefore also the fluid pressure, was limited by reason of the fluid friction, in the form of discharger described, but the practically obtainable speed was more than sufficient to produce a number of breaks suitable for the circuits ordinarily used. In such instances the metal pulley *p* was provided with a few projections inwardly, and a definite number of breaks was then produced which could be computed from the speed of

3419

duced without the discharge gap, and there might even not be any quenched superimposed vibration; yet the differences of potential at the various points of the circuit, the impedance and other phenomena, dependent upon the rate of change, will bear no similarity in the two cases. Thus, when working with currents discharging disruptively, the element chiefly to be considered is not the frequency, as a student might be apt to believe, but the rate of change per unit of time. With low frequencies in a certain measure the same effects may be obtained as with high frequencies, provided the rate of change is sufficiently great. So if a low frequency current is raised to a potential of, say, 75,000 volts, and the high tension current passed through a series of high resistance lamp filaments, the importance of the rarefied gas surrounding the filament is clearly noted, as will be seen later; or, if a low frequency current of several thousand amperes is passed through a metal bar, striking phenomena of impedance are observed, just as with currents of high frequencies. But it is, of course, evident that with low frequency currents it is impossible to obtain such rates of change per unit of time as with high frequencies, hence the effects produced by the latter are much more prominent. It is deemed advisable to make the preceding remarks, inasmuch as many more recently described effects have been unwittingly identified with high frequencies. Frequency alone in reality does not mean anything, except when an undisturbed harmonic oscillation is considered.

In the branch *a* a similar disposition to that in *b* is illustrated, with the difference that the currents discharging through the gap *d d* are used to induce currents in the secondary *s* of a transformer T. In such case the secondary should be provided with an adjustable condenser for the purpose of tuning it to the primary.

a b illustrates a plan of alternate current high frequency conversion which is most frequently used and which is found to be most convenient. This plan has been dwelt upon in detail on previous occasions and need not be described here.

Some of these results were obtained by the use of a high frequency alternator. A description of such machines will be found in my original paper before the American Institute of Electrical Engineers, and in periodicals of that period, notably in THE ELECTRICAL ENGINEER of March 18, 1891.

I will now proceed with the experiments.

3420

coils, also by varying the frequency and potential of the currents. But it is perhaps of greater interest to note, that the lamp increases in brightness when the plate is disconnected (Fig. 179a). In this case all the energy the primary receives is now sunk into it, like the charge of a battery in an ocean cable, but most of that energy is recovered through the secondary and used to light the lamp. The current traversing the primary is strongest at the end *b* which is connected to the terminal t_1 of the induction coil, and

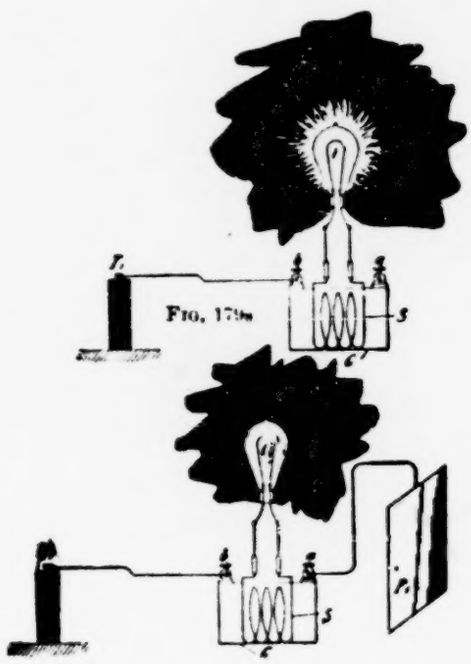

FIG. 179b.

diminishes in strength towards the remote end *a*. But the dynamic inductive effect exerted upon the secondary s is now greater than before, when the suspended plate was connected to the primary. These results might have been produced by a number of causes. For instance, the plate t_1 being connected, the reaction from the coil c may be such as to diminish the potential at the terminal t_1 of the induction coil, and therefore weaken the current through the primary of the coil c. Or the disconnecting

of the plate may diminish the capacity effect with relation to the primary of the latter coil to such an extent that the current through it is diminished, though the potential at the terminal T_1 of the induction coil may be the same or even higher. Or the result might have been produced by the change of phase of the primary and secondary currents and consequent reaction. But the chief determining factor is the relation of the self-induction and capacity of coil c and plate P_1 and the frequency of the currents. The greater brightness of the filament in Fig. 179*a*, is, however, in part due to the heating of the rarefied gas in the lamp by electrostatic induction, which, as before remarked, is greater when the suspended plate is disconnected.

Still another feature of some interest I may here bring to your attention. When the insulated plate is disconnected and the secondary of the coil opened, by approaching a small object to the secondary, but very small sparks can be drawn from it, showing that the electrostatic induction is small in this case. But upon the secondary being closed upon itself or through the lamp, the filament glowing brightly, strong sparks are obtained from the secondary. The electrostatic induction is now much greater, because the closed secondary determines a greater flow of current through the primary and principally through that half of it which is connected to the induction coil. If now the bulb be grasped with the hand, the capacity of the secondary with reference to the primary is augmented by the experimenter's body and the luminosity of the filament is increased, the incandescence now being due partly to the flow of current through the filament and partly to the molecular bombardment of the rarefied gas in the bulb.

The preceding experiments will have prepared one for the next following results of interest, obtained in the course of these investigations. Since I can pass a current through an insulated wire merely by connecting one of its ends to the source of electrical energy, since I can induce by it another current, magnetize an iron core, and, in short, perform all operations as though a return circuit were used, clearly I can also drive a motor by the aid of only one wire. On a former occasion I have described a simple form of motor comprising a single exciting coil, an iron core and disc. Fig. 180 illustrates a modified way of operating such an alternate current motor by currents induced in a transformer connected to one lead, and several other arrangements of circuits

3422

plate P_3. On the primaries are wound secondaries s and s_1, of coarse wire, connected to the devices *d* and *l* respectively. By varying the distances of the condenser plates c and c_1, and c and c_1 the currents through the secondaries s and s_1 are varied in intensity. The curious feature is the great sensitiveness, the slightest change in the distance of the plates producing considerable variations in the intensity or strength of the currents. The sensitiveness may be rendered extreme by making the frequency such, that the primary itself, without any plate attached to its free end, satisfies, in conjunction with the closed secondary, the condition of resonance. In such condition an extremely small change in the capacity of the free terminal produces great variations. For instance, I have been able to adjust the conditions so that the mere approach of a person to the coil produces a considerable change in the brightness of the lamps attached to the secondary. Such observations and experiments possess, of course, at present, chiefly scientific interest, but they may soon become of practical importance.

Very high frequencies are of course not practicable with motors on account of the necessity of employing iron cores. But one may use sudden discharges of low frequency and thus obtain certain advantages of high-frequency currents without rendering the iron core entirely incapable of following the changes and without entailing a very great expenditure of energy in the core. I have found it quite practicable to operate with such low frequency disruptive discharges of condensers, alternating-current motors. A certain class of such motors which I advanced a few years ago, which contain closed secondary circuits, will rotate quite vigorously when the discharges are directed through the exciting coils. One reason that such a motor operates so well with these discharges is that the difference of phase between the primary and secondary currents is 90 degrees, which is generally not the case with harmonically rising and falling currents of low frequency. It might not be without interest to show an experiment with a simple motor of this kind, inasmuch as it is commonly thought that disruptive discharges are unsuitable for such purposes. The motor is illustrated in Fig. 182. It comprises a rather large iron core *i* with slots on the top into which are embedded thick copper washers *c c*. In proximity to the core is a freely-movable metal disc D. The core is provided with a primary exciting coil c_1 the ends *a* and *b* of which are connected to

3423

100-volt and the latter a 50-volt are placed in certain positions as indicated, the 100-volt lamp being below the 50-volt lamp. When the arc is playing at *d d* and the sudden discharges are passed through the bars B B_1, the 50-volt lamp will, as a rule, burn brightly, or at least this result is easily secured, while the 100-volt lamp will burn very low or remain quite dark, Fig. 183*b*. Now the bars B B_1 may be joined at the top by a thick cross bar B_2 and it is quite easy to maintain the 100-volt lamp at full candle-power while the 50-volt lamp remains dark, Fig. 183*c*. These results, as I have pointed out previously, should not be considered to be due exactly to frequency but rather to the time rate of change which may be great, even with low frequencies. A great many other results of the same kind, equally interesting, especially to those who are only used to manipulate steady currents, may be obtained and they afford precious clues in investigating the nature of electric currents.

In the preceding experiments I have already had occasion to show some light phenomena and it would now be proper to study these in particular; but to make this investigation more complete I think it necessary to make first a few remarks on the subject of electrical resonance which has to be always observed in carrying out these experiments.

ON ELECTRICAL RESONANCE.

The effects of resonance are being more and more noted by engineers and are becoming of great importance in the practical operation of apparatus of all kinds with alternating currents. A few general remarks may therefore be made concerning these effects. It is clear, that if we succeed in employing the effects of resonance practically in the operation of electric devices the return wire will, as a matter of course, become unnecessary, for the electric vibration may be conveyed with one wire just as well as, and sometimes even better than, with two. The question first to answer is, then, whether pure resonance effects are producible. Theory and experiment both show that such is impossible in Nature, for as the oscillation becomes more and more vigorous, the losses in the vibrating bodies and environing media rapidly increase and necessarily check the vibration which otherwise would go on increasing forever. It is a fortunate circumstance that pure resonance is not producible, for if it were there is no telling what dangers might not lie in wait for the innocent experimenter. But to a

...degree resonance is producible, the magnitude of the ... being limited by the imperfect conductivity and imperfect elasticity of the media or, generally stated, by frictional losses. The smaller these losses, the more striking are the effects. The same is the case in mechanical vibration. A stout steel bar may be set in vibration by drops of water falling upon it at proper intervals; but with glass, which is more perfectly elastic, the resonance effect is still more remarkable, for a goblet may be burst by singing into it a note of the proper pitch. The electrical resonance is the more perfectly attained, the smaller the resistance or the impedance of the conducting path and the more perfect the dielectric. In a Leyden jar discharging through a short stranded cable of fine wires these requirements are probably best fulfilled, and the resonance effects are therefore very prominent. Such is not the case with dynamo machines, transformers and their circuits, with commercial apparatus in general in which the presence of iron cores complicates the action or renders it impossible. As regard to Leyden jars with which resonance effects are frequently demonstrated, I would say that the effects observed are often *attributed* but are seldom *due* to true resonance, for the error is quite easily made in this respect. This may be undoubtedly demonstrated by the following experiment. Take, for instance, two large insulated metallic plates or spheres which I shall designate a and b; place them at a certain small distance apart and charge them from a frictional or influence machine to a potential so high that just a slight increase of the difference of potential between them will cause the small air or insulating space to break down. This is easily reached by making preliminary trials. If now another plate—fastened on an insulating handle and connected by a wire to one of the terminals of a high tension secondary of an induction coil, which is set in action by an alternator (preferably high frequency)—is approached to one of the charged bodies a or b, so as to approach further one of them, the discharge will invariably pass between them; at least it will, if the potential of the coil and with the plate is sufficiently high. But the explanation will soon be found in the fact that the approached plate acts inductively upon the bodies a and b and causes a spark to pass between them. When this spark occurs, the charges which the bodies had received from the influence machine are partly neutralized, since the bodies are brought in electri-

cal connection through the arc formed. Now this arc is formed whether there be resonance or not. But even if the spark would not be produced, still there is an alternating E. M. F. set up between the bodies when the plate is brought near one of them; the reason the approach of the plate, if it *does* not always actually, will, at any rate, *tend* to break down the air space by inductive action. Instead of the spheres or plates A and B we may take the coatings of a Leyden jar with the same result, and in place of the machine,—which is a high frequency alternator preferably, because it is more suitable for the experiment and also for the argument,—we may take another Leyden jar or battery of jars. When such jars are discharging through a circuit of low resistance the same is traversed by currents of very high frequency. The plate may now be connected to one of the coatings of the second jar, and when it is brought near to the first jar just previously charged to a high potential from an influence machine, the result is the same as before, and the first jar will discharge through a small air space upon the second being caused to discharge. But both jars and their circuits need not be tuned any closer than a basso profundo is to the note produced by a mosquito, as small sparks will be produced through the air space, or at least the latter will be considerably more strained owing to the setting up of an alternating E. M. F. by induction, which takes place when one of the jars begins to discharge. Again another set of a similar nature is quite easily made. If the circuits of the two jars are, say, parallel and close together, and the experiment has been performed of discharging one by the other, and now a coil of wire be added to one of the circuits whereupon the experiment does not succeed, the conclusion that this is due to the fact that the circuits are [illegible] not tuned, would be far from being safe. For the two circuits act as condenser coatings and the addition of the coil across them is equivalent to bridging them, at the point where the coil is placed, by a small condenser, and the effect of the latter might be to prevent the spark from passing through the discharger by diminishing the alternating E. M. F. acting across the [illegible]. All these remarks, and many more which might be added, I refrain [illegible] of wandering too far from the [illegible] permissible idea of confining the [illegible] might gain an entirely [illegible] ing every experiment [illegible] the experimenter as [illegible]

In order to make reliable observations of electric resonance effects it is very desirable, if not necessary, to employ an alternator giving currents which rise and fall harmonically, as in working with make and break currents the observations are not always trustworthy, since many phenomena, which depend on the rate of change, may be produced with widely different frequencies. Even when making such observations with an alternator one is apt to be mistaken. When a circuit is connected to an alternator there are an indefinite number of values for capacity and self-induction which, in conjunction, will satisfy the condition of resonance. So there are in mechanics an infinite number of tuning forks which will respond to a note of a certain pitch, or loaded strings which have a definite period of vibration. But the resonance will be most perfectly attained in that case in which the motion is effected with the greatest freedom. Now in mechanics, considering the vibration in the common medium—that is, air—it is of comparatively little importance whether one tuning fork be somewhat larger than another, because the losses in the air are always considerable. One may, of course, enclose a tuning fork in a chamber exhausted by this reducing the air resistance to a minimum obtain better resonant action. Still the difference would not be very great. But it would make a great difference if the tuning fork were immersed in mercury. In the electrical resonator it is of enormous importance to arrange the conditions so that the vibration is effected with the greatest freedom. The strength of the resonance effect depends, under otherwise equal conditions, on the quantity of electricity set in motion or on the strength of the current driven through the circuit. But the circuit opposes the passage of the currents by reason of its impedancy and this has, to secure the best action it is necessary to reduce the impedance to a minimum. It is impossible to overcome resistance, but nothing in part, for the ohmic resistance cannot be reduced. But when the frequency of the impulses is very great, the flow of the current is practically determined by self induction. This self-induction can be overcome by combining it with capac-

[illegible] that is the frequency [illegible] have such values as to [illegible] the greatest quantity of [illegible] current, that is [illegible] It is clear that in such

combinations there will be, for a given frequency, and consider only the fundamental vibration, values which will give the best result, with the condenser in shunt to the self-induction coil, of course more such values than with the condenser in series. But practical conditions determine the selection. In the latter case in performing the experiments one may take a small self-induction and a large capacity or a small capacity and a large self-induction, but the latter is preferable, because it is inconvenient to adjust a large capacity by small steps. By taking a coil with a very large self-induction the critical capacity is reduced to a very small value, and the capacity of the coil itself may be sufficient. It is easy, especially by observing certain artifices, to wind a coil through which the impedance will be reduced to the value of the ohmic resistance only; and for any coil there is, of course, a frequency at which the maximum current will be made to pass through the coil. The observation of the relation between self-

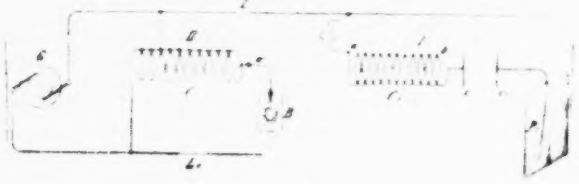

FIG. 184

induction, capacity and frequency is becoming important in the operation of alternate current apparatus, such as transformers or motors, because by a judicious determination of the elements the employment of an expensive condenser becomes unnecessary. Thus it is possible to pass through the coils of an alternating current motor under the normal working conditions the required current with a low e.m.f. and do away entirely with the false current, and the larger the motor, the easier such a plan becomes practicable; but it is necessary for this to employ currents of very high potential or high frequency.

In Fig. 184 L is shown a plan which has been followed in the study of the resonance effects by means of a high frequency alternator. C is a coil of many turns, which is divided into small separate sections for the purpose of adjustment. The final adjustment was made sometimes with a few thin iron wires (though this is not always advisable) or with a closed secondary. The coil

3428

c_1 is connected with one of its ends to the line L from the alternator G and with the other end to one of the plates c of a condenser $c\,c_1$, the plate (c_1) of the latter being connected to a much larger plate P_1. In this manner both capacity and self-induction were adjusted to suit the dynamo frequency.

As regards the rise of potential through resonant action, of course, theoretically, it may amount to anything since it depends on self-induction and resistance and since these may have any value. But in practice one is limited in the selection of these values and besides these, there are other limiting causes. One may start with, say, 1,000 volts and raise the E. M. F. to 50 times that value, but one cannot start with 100,000 and raise it to ten times that value because of the losses in the media which are great, especially if the frequency is high. It should be possible to start with, for instance, two volts from a high or low frequency circuit of a dynamo and raise the E. M. F. to many hundred times that value. Thus coils of the proper dimensions might be connected each with only one of its ends to the mains from a machine of low E. M. F., and though the circuit of the machine would not be closed in the ordinary acceptance of the term, yet the machine might be burned out if a proper resonance effect would be obtained. I have not been able to produce, nor have I observed with currents from a dynamo machine, such great rises of potential. It is possible, if not probable, that with currents obtained from apparatus containing iron the disturbing influence of the latter is the cause that these theoretical possibilities cannot be realized. But if such is the case I attribute it solely to the hysteresis and Foucault current losses in the core. Generally it was necessary to transform upward, when the E. M. F. was very low, and usually an ordinary form of induction coil was employed, but sometimes the arrangement illustrated in Fig. 184 II., has been found to be convenient. In this case a coil C is made in a great many sections, a few of these being used as a primary. In this manner both primary and secondary are adjustable. One end of the coil is connected to the line L_1 from the alternator, and the other line L is connected to the intermediate point of the coil. Such a coil with adjustable primary and secondary will be found also convenient in experiments with the disruptive discharge. When true resonance is obtained the top of the wave must of course be on the free end of the coil as, for instance, at the terminal of the phosphorescence bulb B. This is

3429

easily recognized by observing the potential of a point on the wire or near to the coil.

In connection with resonance effects and the problem of transmission of energy over a single conductor which was previously considered, I would say a few words on a subject which constantly fills my thoughts and which concerns the welfare of all. I mean the transmission of intelligible signals or perhaps even power to any distance without the use of wires. I am becoming daily more convinced of the practicability of the scheme; and though I know full well that the great majority of scientific men will not believe that such results can be practically and immediately realized, yet I think that all consider the developments in recent years by a number of workers to have been such as to encourage thought and experiment in this direction. My conviction has grown so strong, that I no longer look upon this plan of energy or intelligence transmission as a mere theoretical possibility, but as a serious problem in electrical engineering, which must be carried out some day. The idea of transmitting intelligence without wires is the natural outcome of the most recent results of electrical investigations. Some enthusiasts have expressed their belief that telephony to any distance by induction through the earth is possible. I cannot stretch my imagination so far, but I do firmly believe that it is practicable to disturb by means of powerful machines the electrostatic condition of the earth and thus transmit intelligible signals and perhaps power. In fact, what is there against the carrying out of such a scheme? We now know that electric vibrations may be transmitted through a single conductor. Why should we not try to avail ourselves of the earth for this purpose? We must not be frightened by the idea of distance. In the cosmic conflicts counting the mile posts the earth may appear as a large body to that happiest of all men, the mathematician who gauges all by the heavens and by their standard judges the magnitude of this globe, it appears very small. And so I think it must seem to the electrician, for when he considers the speed with which electrical impulses are propagated through the earth all the points of distance must completely vanish.

A piece of good apparatus would be first to know what is the capacity of the earth and what charge it can hold. Though we have no positive evidence of a charged body existing in space without matter, physically theoretical bodies may be found of such character that the earth would be [illegible]

by whatever process it was separated from other bodies—and this is the accepted view of its origin—it must have retained a charge, as occurs in all processes of mechanical separation. If it be a charged body insulated in space its capacity should be extremely small, less than one-thousandth of a farad. But the upper strata of the air are conducting, and so, perhaps, is the medium in free space beyond the atmosphere, and these may contain an opposite charge. Then the capacity might be incomparably greater. In any case it is of the greatest importance to get an idea of what quantity of electricity the earth contains. It is difficult to say whether we shall ever acquire this necessary knowledge, but there is hope that we may, and that is, by means of electrical resonance. If ever we can ascertain at what period the earth's charge, when disturbed, oscillates with respect to an oppositely electrified system or known circuit, we shall know a fact possibly of the greatest importance to the welfare of the human race. I propose to seek for the period by means of an electrical oscillator, or a source of alternating electric currents. One of the terminals of the source would be connected to earth as, for instance, to the city water mains, the other to an insulated body of large surface. It is possible that the outer conducting air strata, or free space, contain an opposite charge and that, together with the earth, they form a condenser of very large capacity. In such case the period of vibration may be very low and an alternating dynamo machine might serve for the purpose of the experiment. I would then transform the current to a potential as high as it would be found possible and connect the ends of the high tension secondary to the ground and to the insulated body. By varying the frequency of the currents and carefully observing the potential of the insulated body at a watching for the disturbance at various neighboring points of the earth's surface resonance might be detected. Should, as the majority of scientific men in all probability believe, the period be extremely small, then a dynamo machine would not do and a proper electrical oscillator would have to be produced and perhaps it might not be possible to obtain such rapid vibrations. But whether this be possible or not, and whether the earth contains a charge or not, and whatever may be its period of vibration, it certainly is possible—for of this we have daily evidence—to produce some electrical disturbance sufficiently powerful to be perceptible by suitable instruments at any point of the earth's surface.

Assume that a source of alternating currents be connected, as in Fig. 185, with one of its terminals to earth (conveniently to the water mains) and with the other to a body of large surface P. When the electric oscillation is set up there will be a movement of electricity in and out of P, and alternating currents will pass through the earth, converging to, or diverging from, the point C where the ground connection is made. In this manner neighboring points on the earth's surface within a certain radius will be disturbed. But the disturbance will diminish with the distance, and the distance at which the effect will still be perceptible will depend on the quantity of electricity set in motion. Since the body P is insulated, in order to displace a considerable quantity, the potential of the source must be excessive, since there would be limitations as to the surface of P. The conditions might be adjusted so that the generator or source S will set up the same electrical movement as though its circuit were closed. Thus it is certainly practicable to impress an electric vibration of at least of a certain low period upon the earth by means of proper machinery. At what distance such a vibration might be made perceptible can only be conjectured. I have on another occasion considered the question how the earth might behave to electric disturbances. There is no doubt that, since in such an experiment the electrical density at the surface could be but extremely small considering the size of the earth, the air would not act as a very disturbing factor, and there would be not much energy lost through the action of the air, which would be the case if the density were great. Theoretically, then, it could not require a great amount of energy to produce a disturbance perceptible at great distance, or even all over the surface of the globe. Now, it is quite certain that at any point within a certain radius of the source S a properly adjusted self-induction and capacity device can be set in action by resonance. But not only can this be done, but another source S1, Fig. 185, similar to S, or any number of such sources, can be set

Fig. 185.

rod is in synchronism with the latter, and the vibration thus intensified and spread over a large area, or a flow of electricity produced to or from the source s. If the same be of opposite phase to the source s. I think that beyond doubt it is possible to operate electrical devices in a city through the ground or pipe system by resonance from an electrical oscillator located at a central point. But the practical solution of this problem would be of incomparably smaller benefit to man than the realization of the scheme of transmitting intelligence, or perhaps power, to any distance through the earth or environing medium. If this is at all possible, distance does not mean anything. Proper apparatus must first be produced by means of which the problem can be attacked and I have devoted much thought to this subject. I am firmly convinced that it can be done and hope that we shall live to see it done.

ON THE LIGHT PHENOMENA PRODUCED BY HIGH-FREQUENCY CURRENTS OF HIGH POTENTIAL AND GENERAL REMARKS RELATING TO THE SUBJECT.

Returning now to the light effects which it has been the chief object to investigate, it is thought proper to divide these effects into four classes: 1. Incandescence of a solid. 2. Phosphorescence. 3. Incandescence or phosphorescence of a rarefied gas; and 4. Luminosity produced in a gas at ordinary pressure. The first question is: How are these luminous effects produced? In order to answer this question as satisfactorily as I am able to do in the light of accepted views and with the experience acquired, and to add some interest to this demonstration, I shall dwell here upon a feature which I consider of great importance, inasmuch as it promises, besides, to throw a better light upon the nature of most of the phenomena produced by high-frequency electric currents. I have on other occasions pointed out the great importance of the presence of the rarefied gas, or atomic medium in general, around the conductor through which alternate currents of high frequency are passed, as regards the heating of the conductor by the currents. My experiments, described some time ago, have shown that, the higher the frequency and potential difference of the currents, the more important becomes the rarefied gas in which the conductor is immersed, as a factor of the heating. The potential difference, however, is, as I then pointed out, a more im-

may remain lighted if the plate be interposed, or may even increase in luminosity. The effect depends on the position of the plate and tube relatively to the coil, and may be always easily foretold by *assuming* that conduction takes place from one terminal of the coil to the other. According to the position of the plate, it may either divert from or direct the current to the tube.

In another line of work the writer has in frequent experiments maintained incandescent lamps of 50 or 100 volts burning at any desired candle power with both the terminals of each lamp connected to a stout copper wire of no more than a few feet in length. These experiments seem interesting enough, but they are not more so than the quiet experiment of Faraday, which has been revived and made much of by recent investigators, and in which a discharge is made to jump between two points of a bent copper wire. An experiment may be cited here which may seem equally interesting. If a Geissler tube, the terminals of which are joined by a copper wire, be approached to the coil, certainly no one would be prepared to see the tube light up. Curiously enough, it does light up, and, what is more, the wire does not seem to make much difference. Now one is apt to think in the first moment that the impedance of the wire might have something to do with the phenomenon. But this is of course immediately rejected, as for this an enormous frequency would be required. This result, however, seems puzzling only at first; for upon reflection it is quite clear that the wire can make but little difference. It may be explained in more than one way, but it agrees perhaps best with observation to assume that conduction takes place from the terminals of the coil through the space. On this assumption, if the tube with the wire be held in any position, the wire can divert little more than the current which passes through the space occupied by the wire and the metallic terminals of the tube; through the adjacent space the current passes practically undisturbed. For this reason, if the tube be held in any position at right angles to the line joining the binding posts of the coil, the wire makes hardly any difference, but in a position more or less parallel with that line it impairs to a certain extent the brilliancy of the tube and its facility to light up. Numerous other phenomena may be explained on the same assumption. For instance, if the ends of the tube be provided with washers of sufficient size and held in the line joining the terminals of the coil, it will not light up, and then nearly the whole of the current, which would otherwise

practice by combining an electric generator with his oscillator. He pointed out what conditions must be observed in order that the period of vibration of the electrical system might not disturb the mechanical oscillation in such a way as to alter the periodicity, but merely to shorten the stroke. He combines a condenser with a self induction, and gives to the electrical system the same period as that at which the machine itself oscillates, so that both together then fall in step and electrical and mechanical resonance is obtained, and maintained absolutely unvaried.

Next he showed a model of a motor with delicate wheelwork, which was driven by these currents at a constant speed, no matter what the air pressure applied was, so that this motor could be employed as a clock. He also showed a clock so constructed that it could be attached to one of the oscillators, and would keep absolutely correct time. Another curious and interesting feature which Mr. Tesla pointed out was that, instead of controlling the motion of the reciprocating piston by means of a spring, so as to obtain isochronous vibration, he was actually able to control the mechanical motion by the natural vibration of the electro-magnetic system, and he said that the case was a very simple one, and was quite analogous to that of a pendulum. Thus, supposing we had a pendulum of great weight, preferably, which would be maintained in vibration by force, periodically applied; now that force, no matter how it might vary, although it would oscillate the pendulum, would have no control over its period.

Mr. Tesla also described a very interesting phenomenon which he illustrated by an experiment. By means of this new apparatus, he is able to produce an alternating current in which the E. M. F. of the impulses in one direction preponderates over that of those in the other, so that there is produced the effect of a direct current. In fact he expressed the hope that these currents would be capable of application in many instances, serving as direct currents. The principle involved in this preponderating E. M. F. he explains in this way: Suppose a conductor is moved into the magnetic field and then suddenly withdrawn. If the current is not retarded, then the work performed will be a mere fractional one; but if the current is retarded, then the magnetic field acts as a spring. Imagine that the motion of the conductor is arrested by the current generated, and that at the instant when it stops to move into the field, there is still the

maximum current flowing in the conductor; then this current will, according to Lenz's law, drive the conductor out of the field again, and if the conductor has no resistance, then it would leave the field with the velocity it entered it. Now it is clear that if, instead of simply depending on the current to drive the conductor out of the field, the mechanically applied force is so timed that it helps the conductor to get out of the field, then it might leave the field with higher velocity than it entered it, and thus one impulse is made to preponderate in e. m. f. over the other.

With a current of this nature, Mr. Tesla energized magnets strongly, and performed many interesting experiments bearing out the fact that one of the current impulses preponderates. Among them was one in which he attached to his oscillator a ring magnet with a small air gap between the poles. This magnet was oscillated up and down 80 times a second. A copper disc, when inserted within the air gap of the ring magnet, was brought into rapid rotation. Mr. Tesla remarked that this experiment also seemed to demonstrate that the lines of flow of current through a metallic mass are disturbed by the presence of a magnet in a manner quite independently of the so-called Hall effect. He showed also a very interesting method of making a connection with the oscillating magnet. This was accomplished by attaching to the magnet small insulated steel rods, and connecting to these rods the ends of the energizing coil. As the magnet was vibrated, stationary nodes were produced in the steel rods, and at these points the terminals of a direct current source were attached. Mr. Tesla also pointed out that one of the uses of currents, such as those produced in his apparatus, would be to select any given one of a number of devices connected to the same circuit by picking out the vibration by resonance. There is indeed little doubt that with Mr. Tesla's devices, harmonic and synchronous telegraphy will receive a fresh impetus, and vast possibilities are again opened up.

Mr. Tesla was very much elated over his latest achievements, and said that he hoped that in the hands of practical, as well as scientific men, the devices described by him would yield important results. He laid special stress on the facility now afforded for investigating the effect of mechanical vibration in all directions, and also showed that he had observed a number of facts in connection with iron cores.

3436-3437

THE WORK OF HERTZ

...the Physical Society of London saw their way to translate and publish a collection of, at any rate, some of these Papers.*

Portrait Study.

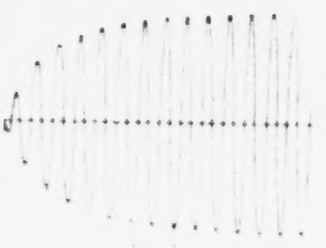
The portrait (Fig. 1) which I show is not a specially pleasing one. It is from a photograph taken by Mr. Yule, one of the band of foreign students who flocked to Hertz's laboratory at Bonn. It is excellent as a photograph, though it fails to represent Hertz at his best, perhaps because it was not taken till after the phrasing of trouble had set in, which ultimately carried him off.

In closing these introductory and personal remarks, I should like to say that the enthusiastic admiration for Hertz's spirit and character, felt and expressed by students and writers who came into contact with him, is not easily to be exaggerated. Never was a man more faithfully attended or watched during the possibilities of illness; and he was accustomed to deprecate the prominence given to him by speakers and writers in this country, lest it might seem to exhalt him unduly above Helmholtz and other workers among his own sensitive countrymen.

Fig. 1.

Speaking of the other great workers in physics in Germany, not out of place to record the sorrow with which we have learnt the recent death of Dr. August Kundt, Professor in the University of Berlin, successor of von Helmholtz in that capacity.

When I consented to discourse on the work of Hertz my intention was to repeat some of his actual experiments and endeavour to demonstrate his less known discoveries and observations. But the frustration exerted upon me by electric oscillations experiments when I, too, was independently working at them in the spring of 1888,† resumed its hold, and my lecture will accordingly be a mere experimental demonstration of the outcome of Hertz's work rather than any precise repetition and performance of his results.



If the loss per swing [illegible] very small [illegible] gradually damped, so that when left to itself it [illegible] to respond [illegible] to [illegible] of about any [illegible] This is the case with [illegible] and the tones of my voice. [illegible] must be extremely slight, for [illegible] they cease to excite the ear.

If, on the other hand, the receiving body has a persistence of vibration [illegible] tumbling after it is left to itself, like an ill-hung [illegible] bell, for instance, then [illegible] facility of response [illegible] great accuracy of tuning [illegible] it is to be fully called [illegible] that the [illegible] is not [illegible] rately synchronised with [illegible] it fails to [illegible] it [illegible] to resound.

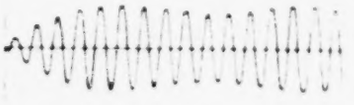


Fig. 2.

Conversely, if the [illegible] a persistent vibration [illegible] essential [illegible] it will destroy it when [illegible] it [illegible] regulated the previous [illegible] Whereas if [illegible] strongly damped [illegible] whatever will respond [illegible] equally ill to it.

What I have said [illegible] sounding bodies [illegible] media competent to transmit waves. Now a sensitive [illegible] a microphone, which speaks to [illegible] waves into [illegible] the radiant energy is likewise able to set up [illegible] tentacles. But we have no delicate means [illegible] these electrical or ethereal waves, and if they are to produce perceptible effect at a distance, they must be [illegible] spreading tube, prevented from spreading, and concentrated on [illegible] distant receiver.

* [illegible] Vol. XXXI. pp. 286, 287. Also [illegible]

† [illegible] Vol. [illegible] p. 27.

This is the function of the telegraph wire; it is to the ether what a speaking tube is to air. A metal wire in air (*in function*, nearly rigid but slightly elastic walls.

Sphere Charge from Electrophorous.

Furthermore, any conductor electrically charged or discharged with sufficient suddenness must emit electrical waves into the ether, because the charge given to it will not settle down instantly, but will surge to and fro several times first, and these surgings or electric oscillations must, according to Maxwell, start waves in the ether, because at the end of each half swing they cause electrostatic, and at the middle of each half swing they cause electromagnetic effects, and the rapid alternation from one of these modes of energy to the other constitutes etherial waves.* If a wire is handy they will run along it, and may be felt a long way off. If no wire exists they will spread out like sound from a bell, or light from a spark, and their intensity will decrease according to the inverse square of the distance.

Maxwell and his followers well know that there would be such waves; they knew the rate at which they would go, they knew that they would go slower in glass and water than in air, they knew that they would curl round sharp edges, that they would be partly absorbed but mainly reflected by conductors, that if turned back upon themselves they would produce the phenomena of stationary waves, or interference, or nodes and loops; it was known how to calculate the length of such waves, and even how to produce them of any required or predetermined wave-length from 1,000 miles to a foot. Other things were known about them which would take too long to enumerate: any homogeneous insulator would transmit them, would refract or concentrate them if it were of suitable shape, would reflect none of a particular mode of vibration at a certain angle, and so on, and so on.

All this was known, I say, known with varying degrees of confidence, but by some known with as great confidence as, perhaps even more confidence than, is legitimate before the actuality of experimental verification.

Hertz supplied the verification. He inserted suitable conductors in the path of such waves, conductors adapted for the occurrence in them of induced electric oscillations, and to the surprise of everyone, himself doubtless included, he found that the secondary electric surgings thus excited were strong enough to display themselves by minute electric sparks.

Syntonic Leyden Jars.

I shall show this in a form which requires great precision of tuning or syntony, both emitter and receiver being persistently vibrating things giving some 30 or 40 swings before damping has a serious effect. I take two Leyden jars with circuits about a yard in diameter, and situated about two yards apart (Fig. 5). I charge and discharge one jar, and observe that the surgings set up in the other can cause it to overflow if it is syntonised with the first.†

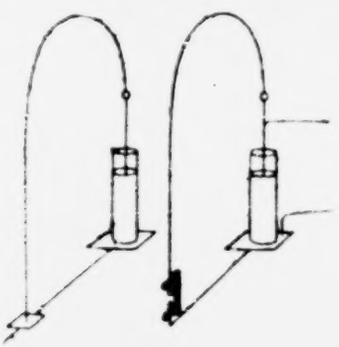

FIG. 5.

A closed circuit such as this is a feeble radiator and a feeble absorber, so it is not adapted for action at a distance. In fact, I doubt whether it will visibly act at a range beyond the $\frac{1}{4}\lambda$ at which true radiation of broken off energy occurs. If the coatings of the jar are separated to a greater distance, so that the dielectric is more exposed, it radiates better; because in true radiation the electrostatic and the magnetic energies are equal, whereas in a ring circuit the magnetic energy greatly predominates. By separating the coats of the jar as far as possible we get a typical Hertz oscil-

FIG. 6.

lator (Fig. 6), whose dielectric extends out into the room, and this radiates very powerfully.

Ordinary Size Hertz Vibrator.

In consequence of its radiation of energy, its vibrations are rapidly damped, and it only gives some three or four good strong swings. Hence it follows that it has a wide range of excitation, i.e., it can excite sparks in conductors barely at all in tune with it.

The two conditions, conspicuous energy of radiation and persistent vibration electrically produced, are at present incompatible. Whenever these two conditions coexist, considerable power or activity will, of course, be necessary in the source of energy. At present they only coexist in the sun and other stars in the electric arc and in furnaces.

Two Circular Vibrators sparking in sympathy.

The receiver Hertz used was chiefly a circular resonator, not a good absorber but a persistent vibrator, well adapted for picking up disturbances of precise and measurable wave-length. I find that the circular resonators can act as senders too; here is one exciting quite long sparks in a second one.

Electric Syntony.—That was his discovery, but he did not stop there. He at once proceeded to apply his discovery to the verification of what had already been predicted about the waves, and by laborious and difficult interference experiments he ascertained that the previously calculated length of the waves was thoroughly borne out by fact. These interference experiments in free space are his greatest achievement.

He worked out every detail of the theory splendidly, separately analysing the electric and the magnetic oscillation, using language not always such as we should use now, but himself growing in theoretic insight through the medium of what would have been to most physicists a confusing maze of troublesome facts, and disentangling all their main relations most harmoniously.

Holtz Machine, A and B Sparks; Glass and Quartz Plates on Screen.

While Hertz was observing sparks such as these, the primary or exciting spark and the secondary or excited one, he observed as a bye issue that the secondary spark occurred more easily if the light from the primary fell upon its knobs. He examined this new influence of light in many ways, and showed that although spark light and electric brush light were peculiarly effective any source of light that gave very ultra violet rays produced the same result.†

Wiedemann and Ebert, and a number of experimenters, have repeated and extended this discovery, proving that it is the cathode knob on which illumination takes effect; and Hallwachs made the important observation, which Righi, Stoletow, Branly, and others have extended, that a freshly polished zinc or other oxidisable surface, if charged negatively, is gradually discharged by ultra violet light.

It is easy to fail in reproducing this experimental result if the right conditions are not satisfied, but if they are, it is absurdly easy, and the thing might have been observed nearly a century ago.

(To be continued.)

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

TO-DAY (FRIDAY), June 8th.

PHYSICAL SOCIETY.

5 p.m. (1) Discussion of the Paper by W. Baly and Prof. Ramsay "On the Relations of Pressure, Volume, and Temperature of Rarefied Gases." (2) An Exhibition of Photographs of Flames by Capt. Abney.

ROYAL INSTITUTION.

9 p.m. Friday Evening Discourse: "The Newtonian Constant of Gravitation," by C. Vernon Boys, F.R.S.

WEDNESDAY, June 13th.

ROYAL SOCIETY.

Ladies' Conversazione.

*** Particulars of meetings to be held or Papers to be read before Scientific Societies during the ensuing week should reach us not later than Thursday, 9 a.m.

* Strictly speaking, in the waves themselves there is no lag or difference of phase between the electric and the magnetic vibrations; the difference exists in emitter or absorber, or both, the transmitting medium. True radiation of energy does not begin till about a quarter wave-length from the source, and within that distance the initial quarter period differs of phase a obliterated.

† See *Nature*, Vol. XLI, p. 368; or *J. J. Thomson. Recent Researches*," p. 396.

‡ The experiments there in the lecture was on the lines of those [illegible] pp. 314 and 340, the con[illegible] described in "*Proc. Roy. Soc.*

absolute values for u and for $-u$, which are equal. It is equal to zero for $u=0$, increases with the increase of u, and for $u=\pm\infty$ tends asymptotically towards the value $\frac{1}{2\pi\overline{L}}$ as its limit. If, then (Fig. 16), we take as abscissæ the values of u, and as ordinates the absolute values of y, and if we take as origin the point O, and as the positive direction of the axis of u the line O X', we find the line F O F_2 which has for asymptote the straight line, L L, parallel to the axis of the abscissæ. In order to find $y_1 - y_2$ we take O $O_1 = n$ and $O_1 p_1 = O_1 p_2 = u$; there results O $p_1 = n - m$, O $p_2 = n + m$, whence the ordinates p_1 P_1 and p_2 P_2 represent y_1 and y_2, and we have at once $y_1 - y_2 = p_1 P_1 - p_2 P_2 = -(p_2 P_2 - p_1 P_1)$.

The mode of variation of this difference appears clear if we draw p_1 P_1 M the line symmetric with respect to O_1 Y_1 to Q P_2 F_2. Now we have $y_1 - y_2 = -P_1 P_2$. We can, if we wish, take this length as ordinate, and thus find, that taking as origin the point O_1 as axis of the ordinates the line O_1 Y_1 and as the positive direction of the axis of abscissæ O_1 X, $y_1 - y_2$ is represented as a function of m by the curve O_1 P M N.

The sign (−) of the value derived from the condition $p_2 P_2 > p_1 P_1$ tells that the flux under consideration rotates towards the left, or in the direction opposed to the movement of the armature. Now this flux, which turns towards the left, produces in the metal of the fixed part of the machine, induced currents on which it then exercises forces tending to draw it from its proper rotation, towards the left. Thence, *vice versâ*, the induced currents in the fixed part of the machine solicit the armature to turn towards the right, in the direction in which it already moves. Whence results that the rotating flux due to the currents in the armature provokes induced currents, which help the rotation, and give place to a couple, which joins to the principal couple of which we spoke in the preceding article. The value of the couple due to the induced currents varies with the variation of m, and increases with the increase of the ordinate p_1 P of the line O_1 M N. It is *zero* for $m=0$ and greatest for $m=n$. Owing to it, the total couple acting on the armature instead of being reduced to zero for $m=O_1$ A (Fig. 15), is not reduced to zero for any value a little larger, a little nearer to n.

Alternating Flux.—The alternating vector resulting from the composition of two vectors rotating in opposite senses, has an amplitude equal to double the smallest of the two component vectors (Art. 4). However, the alternating flux is proportional to

$$\frac{n-m}{\sqrt{r^2+4\pi^2 L^2 (n-m)^2}}$$

It can be zero only for $m=n$.

THE WORK OF HERTZ.*

(*Continued from page 158.*)

Zinc Discharging Negative.—Electricity in Light; Gold Leaf Electroscope; Glass and Quartz Tubes; Quartz Prism.

Take a piece of zinc, clean it with emery paper, connect it to a gold leaf electroscope and expose it to an arc lamp. If charged positively nothing appears to happen, the action is very slow; but a negative charge leaks away in a few seconds if the light is bright. Any source of light rich in ultra violet rays will do; the light from a spark is perhaps most powerful of all. A pane of glass cuts off all the action, so does atmospheric air in sufficient thickness (at any rate town air); hence sunlight is not powerful. A pane of quartz transmits the action almost undiminished, but fluor-spar may be more transparent still. Condensing the arc rays with a quartz lens and analysing them with a quartz prism or reflection grating, we find that the most effective part of the light is high up in the ultra violet, surprisingly far beyond the limits of the visible spectrum. (Figs. 7 and 8).

This is rather a digression, but I have taken some pains to show it properly because of the interest betrayed by Lord Kelvin on this matter, and the caution which he felt about accepting the results of the Continental experimenters too hastily.

It is probably a chemical phenomenon, and I am disposed to express it as a modification of the volta contact effect* with illumination.

Return now to the Hertz vibrator, or Leyden jar with its coatings well separated, so that we can get into its electric as well as its

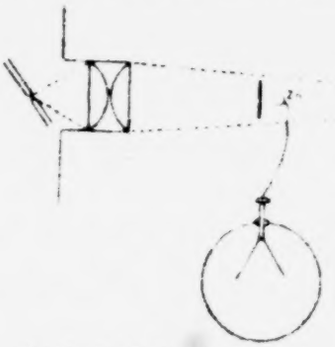

FIG. 7.—Zinc Rod with Glass Screen.

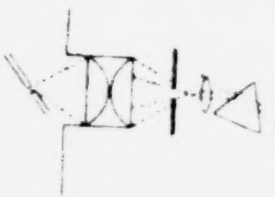

FIG. 8.—Zinc Rod with Ultra violet Light.

magnetic field. Here is a great one giving waves 30 metres long, radiating while it lasts with an activity of 100 *h.p.*, and making ten million complete electric vibrations per second.

Large Hertz Vibrator in action; Abel's Fuse; Vacuum Tubes; Strike no Arc.

Its great radiating power damps it down very rapidly, so that it does not make above two or three swings; but nevertheless, each time it is excited, sparks can be drawn from most of the reasonably elongated conductors in this theatre.

A suitably situated gas leak can be ignited by these induced sparks. An Abel's fuse connecting the water pipes with the gas pipes will blow off; vacuum tubes connected to nothing will glow (this fact has

* A lecture delivered at the Royal Institution on Friday, June 1st, by Prof. Oliver Lodge, F.R.S., ably assisted during both preparation and performance by W. Edward E. Robinson.

* While preparing for the lecture it occurred to me to try if possible, during the course of some new experiments on the effect of light on electricity, the action of rock and ore, because if the effect is not limited to metals it is important in connection with atmospheric electricity. I found that a large mass of iron pyrites in contact with a moist zinc plate was able to work in and out of the varnish during illumination. (*Comptes Rendus*, Vol. CX., p. 808, 1890). Now, the mountain rock of Cornwall, charged with charged earth are exposed to very ultra violet rays at the surface, in which quiet up carrying and sudden downpour of electricity would go on in a manner not very unlike the well known behaviour of water spouts; and this perhaps may be the reason, or one of the reasons why it is not unusual to experience a thunderstorm after a day like this. I have now tried these experiments on such geological specimens as were ready, and find that many of them discharge negative electricity under the action of a naked arc, especially from the side of the specimens which was somewhat dusty, but that when wet they discharge much less rapidly, and when positively charged hardly at all. Iron and garnet and discharge negative electrification, too, under ultra violet illumination, but not so quickly as limestone, much whiter, ferruginous clay, and some other specimens. Granite rarely acts, it seems to be too well. The ice and soil were tried on their usual moist condition, but when thoroughly dry soil discharges quite rapidly. A zinc rod tested was found to discharge as quickly as does a surface of perfectly bright metal, such as iron, but many discharged much more quickly than ordinary dull iron and rather more quickly than when the bright zinc surface is thinly oiled or wetted with water. To-day (June 5) I find that the rock of the geranium discharge positive electrification five times as quickly as negative, under the action of an arc light, and that glass cuts the effect while quartz transmits it.

was familiar to all who have worked with Hertz waves since 1889): electric leads, if anywhere near each other, as they are in some incandescent lamp-holders, may spark across to each other, thus making an arc and blowing their fuses.

The blowing of fuses by electric radiation frequently happened at Liverpool till the suspensions of the theatre lamps were altered.

The striking of an arc by the little reverberating sparks between platinum points connected with the 100 volt mains I incidentally saw at Karlsruhe.

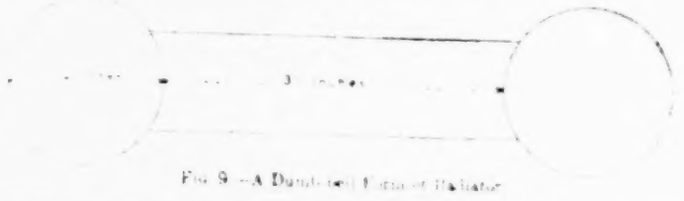

Fig. 9.—A Dumb-bell Form of Radiator.

Fig. 11.

There are some who think that lightning flashes can do none of these things. They are mistaken.

Various specimens of various emitters and receivers have been used by different people (see Table). The radiator of dumb bell type (Fig. 9), the orthodox (Fig. 10), a circular ring (Fig. 11) for interference when it is but little damped, and a straight wire resonator, because it is a much better absorber, by Bjerknes, Voller, Barton, and others, is well known and kept from space dissipation by guiding wires.

Mr Boys has experimented on the mechanical force exerted by electrical surgings, and Hertz also made observations on this kind.

Going back to older methods of detecting electrical radiation we have, most important of all, a discovery made long before it existed, by a creature that developed a sensitive cavity on its [illegible]

Detectors of Radiation.

Chemical	Thermal	Electrical	Mechanical	Visual
Photographic Plate	Thermopile	Spark (Hertz)	Electrometer (Lodge and Rutherford)	Luminous Gas (Hertz)
Explosive Gases	Radiometer (Crookes and Ritter)	Telephone—Air gap and Arc (Dolbear)	Sensitive Wires (Hughes)	Lamp (Lodge)
Dilute Electric Cell	Expanding Wire (Boys)	Vacuum Tube (Crookes)		
	Thermal Junction (Klemencic)	Galvanometer (Fitzgerald)		
		Air gap and Electroscope (Righi and Lodge)		
		Trigger Tube (Watson and Schuster)		

* The cross against the frog's leg indicates that it does not appear really to respond to radiation unless [illegible] The name against the other thumps are unimportant, but suggest the persons who applied the detector to electric radiation. The [illegible] name against the telephone indicates that its position in the microphonic column may be doubtful.

Basic forms are the spheres and ellipsoids (or elliptical plates), which I have mainly used, because they are powerful radiators and absorbers and because their theory has been worked out by Prof. Lamb and J. J. Thomson. Also dumb bells without air gap, and many other shapes, the most recent of mine being the case of a hollow cylinder with sparks at ends of a diameter [illegible] Fig. 12, being a feeble radiator, but a very persistent vibrator,* and, therefore, well adapted for interference and diffraction experiments. But, indeed, spheres can be made to vibrate longer than one by putting them into copper hats or enclosures, in which an aperture of varying size can be made to let the waves out.

Many of these senders will do for receivers too, giving off sparks to other insulated bodies or to earth; but, besides the Hertz type

Fig. 10.—Standard Hertz radiator.

receiver, many other detectors of radiation have been employed. Vacuum tubes can be used, either directly or on the trigger principle as by Zehnder (Fig. 13),† the resonator spark precipitating a discharge from some auxiliary battery or source of energy, and so rendering a feeble disturbance very visible. Explosives may be used for the same purpose, either in the form of mixed water gases or in the form of an Abel's fuse. Fitzgerald found that a tremendously

a creature which never so much as had a name to be remembered by (though, perhaps, we may call it Adinidan). Here, in recent times, we recall the photographic plate and the thermopile with its modification, the radiomicrometer [illegible] and the thermopile with its modification, the radiomicrometer [illegible] or otherwise known Siemens pyrometer applied to astronomy by Langley, applied to the detection of electric waves in wires by

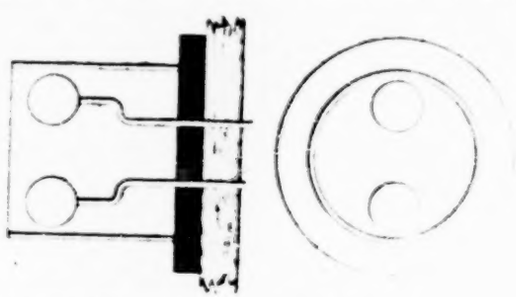

Fig. 12.—Dr. Lodge's Hollow Cylindrical Resonator [illegible] against the Incandescent Lamp Holder Fuse. [illegible]

Rubens and Ritter and Paalzow and Arons [illegible] was applied to the same purpose by Bjerknes, Dr. Barton, and others.

And, before all these, the late Mr Gregory, [illegible] made his singularly sensitive experiments, whereby waves in free space could be detected by the [illegible] and temperature they

* Fitzgerald, Nature, Vol. XLV. [illegible] and Vol. XLVII. p. 172.
† Wied. Ann. XLVII. 77 [illegible]

caused in a platinum wire, a kind of early and sensitive form of Harlew voltmeter.

Going back to the physiological method of detecting surgings, Hertz tried the frog's-leg nerve and muscle preparation, which to the steadier types of electrical stimulus is so surprisingly sensitive, and to which we owe the discovery of current electricity. But he failed to get any result. Ritter has succeeded; but, in my experience, failing in the normal and proper result. Working with my colleague Prof. Gotch, at Liverpool, I too have tried the nerve and muscle preparation of the frog (Fig. 15), and we find that an extremely violent stimulus of a rapidly alternating character, if pure and unaccompanied by secondary actions, produces no effect—no stimulating effect, that is, even though the voltage is so high that sparks are ready to jump between the needles in direct contact with the nerve.

All that such oscillations do, if continued, is to produce a temporary paralysis or fatigue of the nerve, so that it is unable to transmit the nerve impulses evoked by other stimuli, from which paralysis it recovers readily enough in course of time.

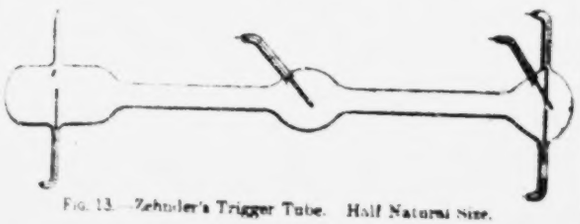

Fig. 13.—Zehnder's Trigger Tube. Half Natural Size.

This has been expected from experiments on human beings, such experiments as Tesla's and those of d'Arsonval. But an entire animal is not at all a satisfactory instrument wherewith to attack the question: its nerves are so embedded in conducting tissues that it may easily be doubted whether the alternating type of stimulus ever reaches them at all. By dissecting out a nerve and muscle from a deceased frog after the historic manner of physiologists, and applying the stimulus direct to the nerve, at the same time as some other well known $\frac{1}{100}$th of a volt stimulus is applied to another part of the same nerve further from the muscle, it can be shown that rapid electric alternations, if entirely unaccompanied by static charge or by resultant algebraic electric transmission, evoke no excitatory response until they are so violent as to give rise to secondary effects such as heat or mechanical shock. Yet, notwithstanding this inaction, they gradually and slowly exert a paralysing or obstructive action on the portion of the nerve to which they are applied, so that the nerve impulse excited by the feeble just perceptible $\frac{1}{100}$th-volt stimulus above is gradually throttled as its way down to the muscle, and remains so throttled for a time varying from a few minutes to an hour after the cessation of the violence.

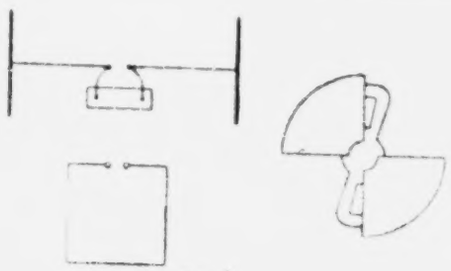

Fig. 14.

I had intended to exhibit this effect, which is very marked and definite, but it is impossible to show everything in the time at my disposal.

Air Gap and Electroscope charged by Blast Rod and discharged by moderately distant Sphere excited by Coil.

Among trigger methods of detecting electric radiation, I have spoken of the Zehnder vacuum tubes; another method is one used by Boltzmann.* A pile of several hundred volts is on the verge of charging an electroscope through an air gap just too wide to break down. Very slight electric surgings precipitate the discharge across the gap, and the leaves diverge. I show this in a modified and simple form. On the cap of an electroscope is placed a highly polished knob or rounded end connected to the sole, and just not touching the cap (Fig. 16). Such an electroscope overflows suddenly and completely with any gentle rise of potential. Bring excited glass near it, the leaves diverge gradually and then suddenly collapse, because the air space maps; remove the glass, and they redivverge with negative electricity; the knob above the cap being then charged positively, and to the verge of sparking. In this condition any electrical waves, collected if weak by a foot or so of wire projecting from the cap, will discharge the electroscope by exciting surgings in the wire, and so breaking down the air gap. The chief interest about this experiment seems to me the extremely definite dielectric strength of so infinitesimal an air space. Moreover, it is a detector for Hertz waves that might have been used last century; it might have been used by Benjamin Franklin.

For to excite them no coil or anything complicated is necessary; it is sufficient to flick a metal sphere or cylinder with a silk handkerchief and then discharge it with a well-polished knob. If it is not well polished the discharge is comparatively gradual, and the vibrations are weak; the more polished are the sides of an air gap the more sudden is the collapse and the more vigorous the consequent radiation, especially the radiation of high frequency, the higher harmonics of the disturbance.

For delicate experiments it is sometimes well to repolish the knobs every hour or so. For metrical experiments it is often

Fig. 15.—Experiment of Gotch and Lodge on the physiological effect of rapid pure electric alternations. Nerve and muscle preparation, with fine needles or size non polarisable electrodes applied to the nerve. C and D are the terminals of a rapidly alternating electric current from a conductor at zero potential, while A and B are the terminals of an ordinary very weak galvanic or induction coil stimulus only just sufficient to make the muscle twitch.

better to let the knobs get into a less efficient but more permanent state. This is true of all senders or radiators. For the generation of the, so to speak, "infra red" Hertz waves any knobs will do, but to generate the "ultra violet" high polish is essential.

Microphonic Detectors.

Receivers or detectors, which for the present I temporarily call microphonic, are liable to respond best to the more rapid vibrations. Their sensitiveness is to me surprising, though of course it does not approach the sensitiveness of the eye, at the same time, I am by no means sure that the eye differs from them in kind. It is these detectors that I wish specially to bring to your notice.

Prof. Minchin, whose long and patient work in connection with photo-electricity is now becoming known, and who has devised an instrument more sensitive to radiation than even Boys radiomicrometer, in that it responds to the radiation of a star while the radiomicrometer does not, found some years ago that some of his slight excitable cells lost their sensitiveness capriciously on tapping, and later he found that they frequently regained it again while Mr. Gregory's Hertz-wave experiments were going on in the same room.

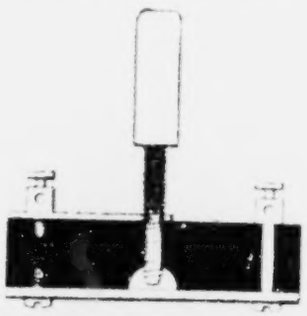

Fig. 16.—Air gap for Electroscope. Natural Size.

These "impulsion cells," as he terms them, are troublesome things for ordinary persons to make and work with, at least I have never presumed to try—but in Mr. Minchin's hands they are surprisingly sensitive to electric waves.*

The sensitiveness of selenium to light is known to everyone, and Mr. Shelford Bidwell has made experiments on the variations of conductivity exhibited by a mixture of sulphur and carbon.

Nearly four years ago M. Edouard Branly found that a burnished coat of porphyrised copper spread on glass diminished its resistance enormously, from some millions to some hundreds of ohms when it was exposed to the neighbourhood, even the distant neighbourhood, of Leyden jars or coil sparks. He likewise found that a tube of metallic filings behaved similarly, but that this recovered its original resistance on shaking. Mr. Croft exhibited this fact

... at once breaks down perhaps not completely, but to a great extent of intensity, but just enough. As I have said, some molecular... within each other's range, incipient cohering occurs, and the momentary electric current acts as it were as a flux. I have a regular variety of electric welding. A stronger stimulus enables more molecules to hold on, the process is surprisingly metrical, and so far as I roughly know at present, the change of resistance is pro... portional to the energy of the electric radiation from a source of given frequency.

It is to be specially noted that the battery current is not needed to effect the cohesion, only to demonstrate it. The battery can be applied after the spark has occurred, and the resistance will be found changed as much as if the battery had been on all the time.

The incipient cohesion electrically caused can be mechanically destroyed. Sound vibrations, or any other feeble mechanical disturbances, such as scratches or taps, are well adapted to restore contact to its original high-resistance sensitive condition. The more feeble the electrical disturbance the slighter is the corresponding mechanical stimulus needed for restoration. When working with a radiating sphere (Fig. 19) at a distance of forty yards or a few, I could not, for this reason, shout to my assistant, to cause him to press the key of the coil and make a spark, but I showed him a duster instead, this being a silent signal which had no disturbing effect on the coherer or tube of filings. I mention 40 yards because that was one of the first outdoor experiments, but I should think that something more like half an mile was nearer the limit of sensitiveness. However, this is a rash statement not at present verified. At 40 yards the exciting spark could be distinctly heard, and it was interesting to watch the spot of light begin its long excursion and actually travel a distance of 2in. or 3in. before the sound arrived

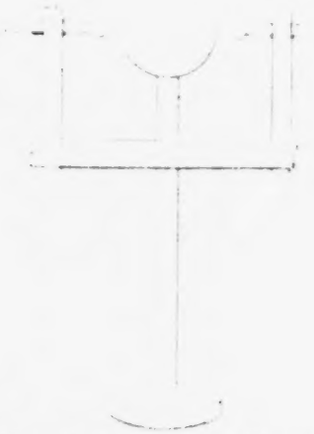

Fig. 19. Electrical signalling in the theatre of the Royal Institution during the Coherer Lecture. The sphere is on the lecture table in the theatre.

This experiment proved definitely enough that the effect was travelled quicker than sound, and disposed completely of all sceptical doubts as to the sound waves being, perhaps, the real cause of the phenomenon.

Invariably, when the receiver is in good condition, sound or other mechanical disturbance acts one way, viz., in the direction of increasing resistance, while electrical radiation invariably acts the other way, decreasing it. While getting the receiver into condition, or when it is getting out of order, vibration and sometimes electric discharges act irregularly, and an occasional good shaking clears the filings good. I have taken rough measurements of the resistance by the simple process of restoring the original galvanometer deflection by adding or removing resistance coils. A light coil of fine iron, of selected iron turnings, had a resistance of 2 ohms, but in the sensitive state. A feeble stimulus, caused by a distant electrical phoros spark, brought it down 400 ohms. A further stimulus reduced it by 200 and 100, while a trace of spark given to a part of the circuit itself, ran it down 1,000 ohms.

This is only to give an idea of the quantities. I have not yet done any seriously metrical experiments.

From the wall diagram which summarises the various devices and which were prepared a month or so ago, I see I have omitted selenium, a substance which in certain states is well known to behave to visible light as these other manipulators behave to Hertz waves.

And I want to suggest that there possibly the sensitiveness of the eye is of the same kind. As I am not a physiologist I cannot be seriously blamed for making wild and hazardous speculations in that region. I therefore wish to express that some part of the retina is an electrical organ, say like that of some fishes, maintaining an electromotive force which is prevented from stimulating the nerves

solely by an intervening layer of badly conducting material, or of conducting material with gaps in it; but that when light falls upon the retina these gaps become more or less conducting, and the nerves are stimulated.

I do not feel clear which part is taken by the rods and cones, and which part by the pigment cells; I must not try to make the hypothesis too definite at present.

If I had to make a demonstration model of the eye on these lines, I should arrange a little battery to excite a frog's nerve and muscle preparation through a circuit completed all except a layer of filings or a single bad contact. Such an arrangement would respond to Hertz waves. Or, if I wanted actual light to act instead of grosser waves, I would use a layer of selenium.

But the bad contact and the Hertz waves are the most instructive, because we do not at present really know what the selenium is doing, any more than what the retina is doing.

And observe that (to my surprise, I confess) the rough outline of a theory of vision thus suggested is in accordance with some of the principal views of the physiologist Hering. The sensation of light is due to the electrical stimulus; the sensation of black is due to the mechanical or tapping back stimulus. Darkness is physiologically not the mere cessation of light. Both are positive sensations, and both stimuli are necessary, for until the filings are tapped back vision is persistent. In the eye model, the period of mechanical tremor should be, say, $\frac{1}{10}$th second, so as to give the right amount of persistence of impression.

No doubt in the eye the tapping back is done automatically by the tissues, so that it is always ready for a new impression, until fatigued. And by mounting an electric bell or other vibrator on the same board as a tube of filings, it is possible to arrange so that a feeble electric stimulus shall produce a feeble steady effect, a stronger stimulus a stronger effect, and so on, the tremor asserting its predominance, and bringing the spot back whenever the electric stimulus ceases.

An electric bell thus close to the tube is, perhaps, not the best vibrator: clockwork might do better, because the bell contains in itself a jerky current, which produces one effect, and a mechanical vibration, which produces an opposite effect; hence the spot of light can hardly keep still. By lessening the vibration—say, by detaching the bell from actual contact with the board, the electric jerks of the intermittent current drive the spot violently up the scale: mechanical tremor brings it down again.

You observe that the eye on this hypothesis is, in electrometer language, heterostatic. The energy of vision is supplied by the organism; the light only pulls a trigger. Whereas the organ of hearing is idiostatic. I might draw further analogies, about the effect of blows or disorder causing irregular conduction and stimulation of the galvanometer in the one instrument, of the brain cells in the other.

A handy portable exciter of electric waves is one of the ordinary hand electric gas lighters, containing a small revolving doubler—an inductive or replenishing machine. A coherer can feel a gas lighter across a lecture theatre. Minchin often used them for stimulating his impulsion cells. I find that when held near they act a little before the spark occurs, plainly because of the little incipient sparks at the brushes or tinfoil contacts made. A Voss machine acts similarly, giving a small deflection while working up before it sparks. And notice here that our model eye has a well-defined range of vision. It cannot see waves too long for it.

(To be concluded.)

ELECTRICAL TRADES SECTION.

The members of the Electrical Trade Section of the London Chamber of Commerce met in the afternoon of Thursday, June 7th, at the offices, Rudolph House, Eastcheap, under the presidency of Major Flood Page.

After the usual preliminaries were disposed of, the CHAIRMAN said that the members would remember that when they did him the honour of appointing him to the chair he accepted the office on condition that the appointment should be for only two years. The subject was discussed pretty freely at the time, and the conclusion that it would be far better that they should have a change of Chairman every two years. For that period he had presided over the Section, and he now took the opportunity of thanking them for the kindness and forbearance with which they had treated him during the time he had held that honourable position. He had been, more or less, in bad health the whole time, and had not been as active, perhaps, as he might otherwise have been. He proposed that it now became his privilege to nominate his successor, and he had great pleasure in proposing that Mr. Emile Garcke should be elected to the office.

Mr. SELLON seconded the motion, which was agreed to unanimously.

Mr. GARCKE, having taken the chair, said that while thanking them for the confidence which they reposed in him by placing him in that responsible position, he felt that he occupied it under the great disadvantage of its having been filled first by Mr. Crompton and then by Major Flood Page. He could but say that he would do his best to perform his duties to the satisfaction of the members. He would like to refer to the very valuable services rendered to the Section by Major Flood Page during his period of office, and to propose a vote of thanks to him for his services. Although that gentleman had not enjoyed the best of health, they must all recognise that he had devoted a great deal of time to the interests of the Section with the result that they had been enabled to carry out some very important business matters in which they were all interested, such as the subject of overhead wires and various other questions which had to go before the Board of Trade, in connection with which Major Flood Page had rendered very valuable service.

A MEMBER briefly seconded the motion, which was cordially passed.

Major FLOYD PAGE, in expressing his acknowledgment, said that he would be still able to be of some little use to the Section, because the Council had done him the honour of electing him to be a permanent member of that body, and therefore, in addition to the fact that Mr. Garcke, as Chairman of the Section, would be entitled to attend the meetings of the Council, he (Major Flood Page) would always be there to act upon any suggestion which Mr. Garcke might recommend.

On the motion of the CHAIRMAN, seconded by Mr. SYDNEY MORSE, Mr. Siemens was elected Deputy-Chairman.

After a short discussion, a committee was formed to watch the interests of the Section in connection with the rating of electric works, and a letter was read on the subject of the Locomotive Act from the Board of Trade, intimating that the representations of the Section on the question of their amendment had been brought to the notice of the Home Office.

The consideration of the provisions of the Electric Lighting Act with regard to alleged nuisances was left in the hands of the same committee.

On the suggestion of the CHAIRMAN, seconded by Mr. MORSE and supported by Mr. SELLON, it was decided to circularise the various departments of the electrical industry, urging upon them the desirability of supporting the Section in promoting the interests appertaining to each.

The proceedings then ended.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *June 2, 1894.*

New Telephone Rates. The local New York City Telephone Company on June 1st introduced a new system of charges for telephone service, based upon the number of messages sent by a subscriber. All lines will be metallic circuits, and the subscriber sending messages of not less than 1,000, nor over 2,000 annually, may elect if he will have a line for his sole use or share one with another subscriber. The lowest annual rate, $100, is for "two party" lines only and 700 messages, the charge for additional messages being $15 per 100. The highest rate for a "direct" line is $150 per annum, 1,000 messages being the limit, the charge for those in excess of that number being $12 per 100. A "two party" line for this service costs $ less per annum. For 2,000 messages per annum the charge for a "direct" line is $220, and for a "two party" line, excess messages being $8 per 100. For [illegible] messages "direct" lines only can be used, and the rate will be $5 per 100, with $7 per 100 for excess messages.

Central Stations in Massachusetts. [illegible] Board of the Gas and Electric Light Commissioners of Commonwealth of Massachusetts for [illegible] the last year out of [illegible] central electric light stations in State 28 paid dividends, 20 paid [illegible] earn expenses. Of the $ [illegible] stations paid $ [illegible], and the [illegible] the greater part of the remainder [illegible] those of Boston, paid 7 per cent. [illegible] per cent. and two 5 per cent. The [illegible] companies were returned at $ [illegible] surplus of $ [illegible].

3445

...course, if an alternating current supply is available, and a suitable voltmeter, the method may be modified by putting the voltmeter in place of the galvanometer and using alternating current in the primary P. The voltmeter would have to be of high resistance, or an electrostatic one.

Without a galvanometer at all, a very rough test may be made by simply placing a compass needle at the centre of the coil, and observing its deflections when one pole of a battery (with high resistance in circuit) is connected to the bobbin, whilst the other pole is touched successively to the two free ends of the coil.

THE WORK OF HERTZ *

(Concluded from page 196.)

Sparks not to Long Tube except by help of a polished knob.

The powerful disturbance caused by the violent flashes of a Wimshurst or Voss machine it is blind to. If the knobs of the machine are well polished it will respond to some high harmonics, due to the vibrations in the terminal rods, and these are the vibrations to which it responds when excited by a coil. The coil should have knobs instead of points. Sparks from points or dirty knobs hardly excite the coherer at all. But hold a well polished sphere or third knob between even the dirty knobs of a Voss machine, and the coherer responds at once to the surgings got up in it.

Feeble short sparks again are often more powerful exciters than are strong long ones. I suppose because they are more sudden.

This is instructively shown with an electrophorus lid. Spark it to a knuckle, and it does very little. Spark it to a knob and it works well. But now spark it to an insulated sphere, there is some effect. Discharge the sphere, and take a second spark, without recharging the lid. Do this several times, and at last, when the spark is inaudible, invisible, and otherwise imperceptible, the coherer some yards away responds more violently than ever, and the spot of light rushes from the scale.

If a coherer be attached by a side wire to the gas pipes, and an electrophorus spark be given to either the gas pipes or the water pipes or even to the hot water system in another room of the building, the coherer responds.

In fact, when thus connected to gas ... one day when I tried it, the spot of light could hardly keep five seconds still. Whether there was a distant thunderstorm, or whether it was only picking up telegraphic jerks, I do not know. The jerk of turning on or off an extra Swan lamp can affect it when sensitive. I hope to try for long wave radiation from the sun, filtering out the only very well known waves by a thick board or other sufficiently opaque substance.

We can easily see the difference in regard to a distant source of radiation now, viz., to have the coherer placed in the library between two knobs.

Also I exhibit a small complete detector made by my assistant, Mr. Davies, which is quite portable and easily set up. The essentials are all in a copper cylinder three inches by two. A bit of wire about two inches long, pegged into it, helps it to collect waves. It is just conceivable that at some distant date, say by dint of inserting gold wires or powder in the rotus, we may be enabled to see waves which at present we are blind to.

Observe how simple the production and detection of Hertz waves are now. An electrophorus or a frictional machine serves to excite them, a voltaic cell, a rough galvanometer, and a bad contact serves to detect them. Indeed, they might have been observed at the beginning of the century, before galvanometers were known. A frog's leg or an iodide of starch paper would do almost as well.

A bad contact was at one time regarded as a simple nuisance because of the singularly uncertain and capricious character of the current transmitted by it. Hughes observed its sensitiveness to sound waves, and it became the microphone. Now it turns out to be sensitive to electric waves if it be made of any oxidisable metal (not of carbon), and we have an instrument which might be called a micro something, but which, as it appears to act by cohesion, I call at present a coherer. Perhaps some of the capriciousness of an anathematised bad contact was sometimes due to the fact that it was responding to stray electric radiation.

The breaking down of cohesion by mechanical tremour is an ancient process, observed on a large scale by engineers in rails, axles and girders. Indeed, the cutting of small girders by persistent blows of hammer and chisel reminded me the other day of the tapping back of our cohering surfaces after they have been exposed to the welding effect of the electric jerk.

* A lecture delivered at the Royal Institution on Friday June 1st, by Prof. Oliver Lodge, F.R.S., ably assisted during both preparation and performance by Mr. Edward E. Robinson.

If a coherer is shut up in a complete metal enclosure ... cannot get at it, but if wires are led from it to an outside ... galvanometer, it remains nearly as sensitive as it was before (not quite), for the circuit picks up the waves and they run ... the insulated wires into the closed box. To screen it effectively, it is necessary to enclose battery and galvanometer and every bit of wire connection; the only thing that may be left outside is the needle of the galvanometer. Accordingly, here we have a complete arrangement of battery and coil and coherer, all shut up in a copper box. The coil is fixed against the side of the box at such height that it can act conveniently on an outside suspended compass needle. The slow action of the coil has no difficulty in getting through copper, as everyone knows; only a perfect conductor could screen off that, but the Hertz waves are effectively kept out by sheet copper.

It must be said, however, that the box must be exceedingly well closed for the screening to be perfect. The very narrowest chink permits their entrance, and at one time I thought I should have to solder a lid on before they could be kept entirely out. Clamping the copper lid on to a flange in six places was not enough. But by the use of pads of tinfoil, chinks can be avoided, and the inside of the box becomes then electrically dark.

If even an inch of the circuit protrudes, it at once becomes slightly sensitive again; and if a single branch wire protrudes through the box, provided it is insulated where it passes through, the waves will utilise it as a speaking tube, and run blithely in. And this whether the wire be connected to anything inside or not, though it acts more strongly when connected.

If wires are to be taken out of the box to a coherer in some other enclosure, they must be enclosed in a metal tube, and this tube must be well connected with the metal of both enclosures, if nothing is to get in but what is wanted.

Similarly, when definite radiation is desired, it is well to put the radiator in a copper hat, open in only one direction. And in order to guard against reflected and collateral surgings running along the wires which pass outside to the coil and battery, as they are liable to do, I am accustomed to put all these things in a packing case lined with tinfoil, to the outside of which the sending hat is fixed, and to pull the key of the primary exciting circuit by a string from outside.

With reference to the reflecting power of different substances it may be interesting to give the following numbers, showing the motion of the spot of light when 8in. waves were reflected into the copper box, the angle of incidence being about 45deg., by the following mirrors:—

Sheet of window glass	0 or at most 1 division.
Human body	7 divisions.
Drawing board	12
Towel soaked with tap water	12
Tea paper (lead)	40
Dutch metal paper	70
Tinfoil	80
Sheet copper	100 and up to one scale.

Even then, with the lid of the hat well clamped on, something gets out, but it is not enough to cause serious disturbance of qualitative results. The sender must evidently be thought of as emitting a momentary blaze of light which escapes through every chink or, indeed, since the waves are some inches long, the difficulty of keeping them out of an enclosure may be likened to the difficulty of excluding sound, though the difficulty is not quite so great as that, since a reasonable thickness of metal is really opaque. I fancied once or twice I detected a trace of transparency in such metal sheets as ordinary tinplate, but unnoticed chinks elsewhere may have deceived me. It is a thing easy to make sure of as soon as I have more time.

One thing in this connection is noticeable, and that is how little radiation gets either in or out of a small round hole. A narrow long chink in the receiver box lets in a lot; a round hole the size of a shilling lets in hardly any, unless, indeed, a bit of insulated wire protrudes through it like a collecting ear trumpet.

It may be asked how the waves get out of the metal tube of an electric gas lighter. But they do not; they get out through the handle, which being of ebonite is transparent. Wrap up the handle tightly in tinfoil, and a gas lighter is powerless.

Optical Experiments.

And now in conclusion I will show some of the ordinary optical experiments with Hertz waves, using as source either one of two devices; either a 5in. sphere with sparks to ends of a diameter (Fig. 20), an arrangement which emits 9in. waves, but of so dead beat a character that it is wise to enclose it in a copper hat to prolong them, and send them out in the desired direction; or else a 2in. hollow cylinder with spark knobs at ends of an internal diameter. This last emits 3in. waves of a very fairly persistent character, but with nothing like the intensity of one of the outside radiators.

As receiver there is no need to use anything sensitive, so I employ a glass tube full of coarse iron filings, put at the back of a copper hat with its mouth turned well askew to the source.

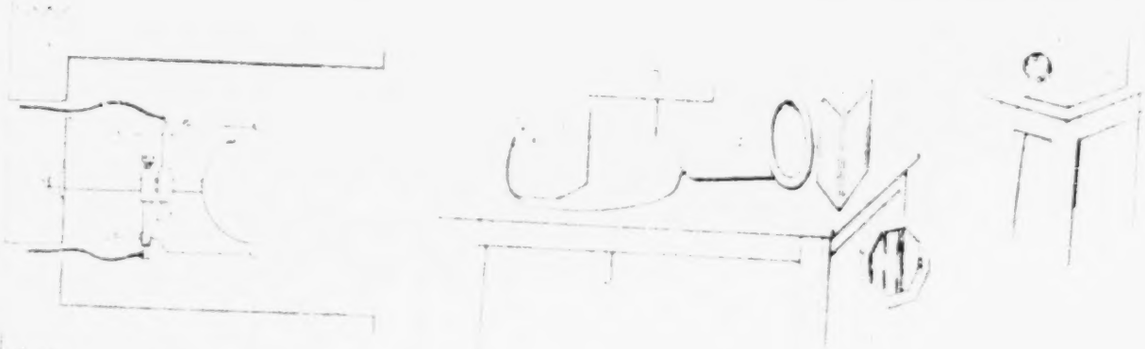
which is put outside the door at a distance of some yards, so that only a little direct radiation can reach the tube. Sometimes the tube is put lengthways in the hat instead of crossways, which makes it less sensitive, and has also the advantage of doing away with the polarising or rather analysing power of a crossway tube.

The radiation from the sphere is still too strong, but it can be stopped down by a diaphragm plate with holes in it of varying size clamped on the sending hat.

Having thus reduced the excursion of the spot of light to a foot or so, a metal plate is held as reflector, and at once the spot travels a couple of yards. A wet cloth reflects something, but a thin glass plate, if dry, reflects next to nothing, being, as is well known, too thin to give anything but "the black spot." I have fancied that it reflects something of the 3in. waves.

Refracting Prism and Lens.

A block of paraffin about a cubic foot in volume is cast into the shape of a prism with angles 75deg., 60deg., and 45deg. Using the large angle, the rays are refracted into the receiving hat (Fig. 2), and produce an effect much larger than when the prism is removed.



Ordinary flint glass lens is next placed near the source, and by means of the light-spot it is focussed between source and receiver. The lens is seen to increase the effect.

Using Glass Cylinders as Lenses.

The lens helps us to set correctly an 18in. circular copper disc position for showing the bright diffraction spot. Removing the lens the effect is much the same as when it was present. Add the lens and the effect is greater. With a diffraction grating of copper strips 2in. broad and 2in. apart, I have not yet succeeded in getting good results. It is difficult to get sharp nodes and interference bands with these sensitive detectors in a room. I expect to do better when I can try out of doors away from so many reflecting surfaces. Indoors it is like trying delicate optical experiments in a small whitewashed chamber well supplied with looking glasses. Nor have I ever succeeded in getting clear concentration with this zone plate having Newton rings based to it in tinfoil. But really there is nothing of much interest now in diffraction effects except the demonstration of the waves and the measure of their length. There was immense interest in Hertz's time, because then the wave character of the radiation had to be proved, but every possible kind of wave must give interference and diffraction effects, and their theory is, so to say, worked out. More interest attaches to polarisation, double refraction, and dispersion experiments.

Polarising and Analysing Grid.

Polarisation experiments are easy enough. Radiation from a sphere is already strongly polarised, and the tube acts as a partial analyser, responding much more vigorously when its length is parallel to the line of sparks than when they are crossed; but a convenient extra polariser is a grid of wires something like what was used by Hertz only on a much smaller scale, say an 18in. octagonal frame of copper strip with a harp of parallel copper wires (see Fig. 2). The spark line of the radiator being set at 45deg., a vertical grid placed over receiver reduces the deflection to about one-half, and a crossed grid over the source reduces it to nearly nothing. Rotating either grid a little rapidly increases the effect, which becomes a maximum when they are parallel. The interposition of a third grid, with its wires at 45deg. between those of the two, restores some of the obliterated effect.

Radiation reflected from a grid is strongly polarised, the normal, of course, to that of the radiation which excites it. They are thus analogous in their effect to Nicol's prisms of plates.

The electric vibrations which get through the grid are at right angles to the wires. Vibrations parallel to the wires are reflected or absorbed.

Reflecting Paraffin Prism.

To demonstrate that the so-called plane of polarisation of radiation transmitted by a grid is at right angles to the plane of vibration,* i.e., that when light is reflected from the boundary of a transparent substance at the polarising angle the electric vibrations of the reflected beam are perpendicular to the plane of incidence, I use the same paraffin prism as before; but this time I employ the largest face as a reflector, and set it at something near the polarising angle. When the line of wires is parallel to the plane of incidence, plenty of radiation is reflected by the paraffin face. Turning the grid so that the electric vibrations are parallel to the plane of incidence, we find that the paraffin [illegible] angle is able to reflect hardly anything. [illegible] the effects investigated by Fresnel and the [illegible] dealt with by M. Cailletet are the necessary [illegible] Time does not allow of the introduction [illegible] to the wayfaring man.

A NEW PHENOMENON OBSERVED IN THE PASSAGE OF ELECTRICITY THROUGH BADLY CONDUCTING LIQUIDS.†

BY G. TRAUBE.

During the electrolysis of good liquid conductors the [illegible] known to be confined to the proximity of the electrodes. [illegible] as I know, no chemists have hitherto been observed in the case of badly conducting liquids of weak dissociation, such as water and electric currents on the other hand. I have observed [illegible] of electricity through certain badly conducting liquids, such as [illegible] of aniline dyes, to be attended by changes proceeding [illegible] continuously from the electrodes to the centre, usually by the formation of a precipitate in the middle of the liquid [illegible] between the electrodes. The phenomena are most easily [illegible] by means of a microscope and an arrangement [illegible] scribed.

If, for instance, a current of about 20 volts pressure [illegible] through an aqueous solution of Congo red, a crystalline [illegible] halo is formed round both electrodes of a somewhat [illegible] the anode and somewhat paler than the rest. The [illegible] cathode, but divided off from it by a darker boundary [illegible]

The Art of Soldering. By William [illegible] Municipal Technical [illegible] Birmingham.

It is impossible to discuss the whole art of soldering in a little pamphlet of 32 pages, but the author has put together some very useful notes on the chemistry of fluxes, the composition of hard and soft solders, and gives a few practical hints about their use. The bridges peculiar to electrical work are not mentioned; but even those electricians and there are many who can handle a bit or blowpipe in a way that satisfies an old navy tinsmith, and can achieve results of soldering which a new recruit would have believed impossible, may find something worth knowing in Mr. [illegible]'s little book.

THE WORK OF HERTZ.

CORRECTIONS AND EXPLANATIONS BY THE LECTURER.

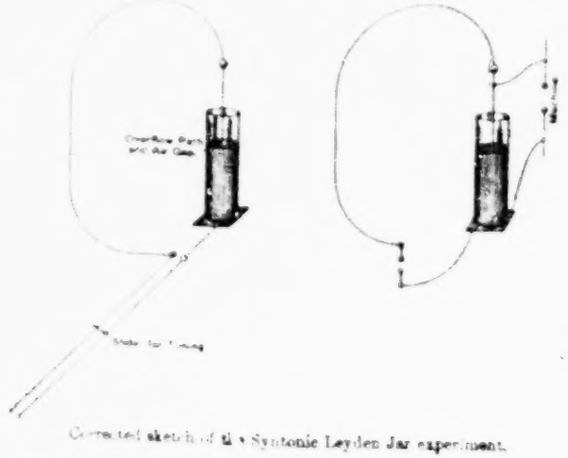
In connection with the illustrations to a lecture of mine at the Royal Institution, recently reported in *The Electrician* for 9th, 16th, 23rd, there are some misapprehensions which may be well to set right for the benefit of students and others who may wish to repeat some of the experiments. Many of the experiments lend themselves to easy repetition, since they involve nothing novel in the way of apparatus except what is quite easily constructed; many of them can be performed with the ordinary stock apparatus of an amateur's laboratory.

Figs. 2, 3, and 4 (page 154) are curves obtained by Hjerkness with the apparatus depicted in Fig. 14, which is intended to show

1. A Hertz vibrator connected to an induction coil.
2. A closed-circuit receiver properly tuned with the vibrator, and
3. A suitable electrometer for inserting in the arrangement.

The receiver is not provided with knobs, as depicted in Fig. 14, but its open circuit is terminated by the quadrants of the electrometer, which is shown on an enlarged scale alongside. The needle is at zero potential and is attracted by both quadrants. By calculation from the indications of this electrometer Hjerkness plotted the curves Figs. 2, 3, and 4. Fig. 2 represents the oscillations of the primary vibrator, rapidly stopped by radiation of energy. Fig. 3 represents the wave-train thereby set up in the resonating circuit when the two are accurately in tune, and which persist for many swings. Fig. 4 shows the oscillations excited in the same circuit when slightly out of tune with the exciter. A receiver of this kind makes many swings before it is seriously damped.

In Fig. 3 the emitting circuit is properly shown, but the receiving circuit is not shown properly. The following sketch is correct.



Corrected sketch of the Syntonic Leyden Jar experiment.

Fig. 6, if its plates and rods are magnified enormously without magnifying the knobs, may serve to represent the gigantic vibrator mentioned on pages 186 and 187: whereas the ordinary 5 m. Hertz vibrator is shown in Fig. 10, on a scale about an inch to a foot.

A new figure, Fig. 7, may be added instead of the last [illegible] note on page 186, to illustrate the arrangement by which I showed the effect on one spark of the light from another. It will be observed that with this arrangement the B knobs are at the same potential up to the instant of the flash, and in that case the ultra-violet portion of the light of the A spark causes the occurrence of the B spark. But it is interesting to note, what Elster and Geitel have found, that if the B knobs were subjected to steady strain instead of impulsive strain, i.e. if they were connected to the [illegible] instead of the outer coatings, then the effect of the ultra-violet light on either spark gap would be to [illegible] the [illegible] diminish, so that the spark would [illegible] extinguished, as it were. With [illegible] it would not be possible to illuminate the sparks by the light of the other, the sparks are then alternative not successive.

The work of Elster and Geitel [illegible] mentioned in the penultimate paragraph of [illegible] reviewed in a separate article which is shortly to appear in *The Electrician*.

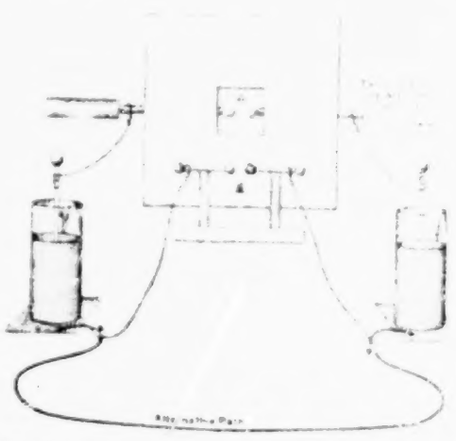


Fig. 22.—Layout arranged to show effect of one spark of light on another. The B sparks were made easier by light cast on the A sparks through the end window in the middle, with a lens. A quartz lens transmits the effect.

With reference to the silent discharging power of light for negative electricity from clean metallic surfaces, Fig. 8 is drawn much as the experiment was shown, it being understood that the lenses are of quartz, not glass. But there is no need to condense the beam at all in this experiment, the naked arc acts powerfully on clean zinc or aluminium, or, indeed, on most metals. But if there be a few minutes' delay after sandpapering the surfaces the effect is very noticeably diminished. In Fig. 8 all the optical parts are of quartz, and the position of the zinc sphere indicates its position in the most effective region of ultra violet light.

A few lines below Fig. 9 the references in the text have got mixed: the reference to Fig. 9 should be to Fig. 10, and the reference to Fig. 10 should be deleted. The knobs of Fig. 11 should be nearly in contact. Fig. 12 is not a resonator or receiver, but an emitter; it emits a long series of 3m. waves at each spark, and it was arranged against the outside of a tinfoil lined box containing battery and induction coil for exciting it. Alongside of it and outside the same box was arranged the larger radiator, Fig. 20, the wires from which pass into the box through glass tubes, and are there connected with the terminals of the secondary coil. The object of this metal lined box or packing-case is to keep in all the stray waves, which else are liable to start from any part of the circuit, &c., to insure that the ostensible source shall likewise be the real one. The sending arrangement shown in Fig. 21 would do very well, but the box should be of metal. The wires of the receiving circuit are screened from direct radiation by being inclosed in a compo pipe.

Fig. 18 does not represent what I have called a coherer, but a simple tube of iron borings or filings, as used by me following M. Branly. Fig. 17 is the coherer, though the spiral should be longer to give elasticity enough, and no "stop" is desirable as the pressure has to be regulated by trial. The contact best adapted for sensitiveness is one with quite appreciable pressure. Some practice is needed to work with these things.

The spherical radiator shown in Fig. 19, which was at pleasure either two inches or five inches in diameter, though it could excite the filings tube Fig. 18 when 60 yards away in the open air, yet could not excite it perceptibly when screened off by so many walls and metal surfaces as exist between the Library and Theatre of the Royal Institution. It could, however, still easily excite the coherer, which is immensely more sensitive, and also more troublesome and occasionally capricious than is a tube of iron filings.

In Fig. 16 the handle should be shown of ebonite too, to permit a delicate adjustment without discharge. The instrument is intended to be placed on, or otherwise connected with, the cap of an electroscope, while the left hand terminal is connected to its sole or outer case. Any electrification then given to the right hand screw soon causes overflow at the excessively minute spark-gap inside. The leaves only diverge a little way and then suddenly collapse.

FIG. 23.—Zonoplate of Tinfoil on Glass.

A zone plate or series of rings of equal area, made of tinfoil pasted upon glass with alternate spaces bare, is shown in Fig. 23 herewith, and is intended to act as a diffraction lens, concentrating to a focus the 3in. waves from the radiator Fig. 12.

Lastly, a table of numbers interpolated in the second column of page 204, beginning "with reference to the reflecting power . . . ." and ending "up against stops," is seriously out of its places, since it interrupts the sense of another paragraph. It belongs properly just above the first italic heading on page 205.

The account of the "optical experiments" given towards the end of the lecture is very compressed. It may be well to give a few additional remarks on this subject in another article.

ARC LIGHTING AT HASTINGS.

On Saturday last the occasion of the first lighting up by arc lamps of the entire length of the Hastings and St. Leonards sea front and promenade, extending from the extreme easterly point, known as the Fish Market, to the west end of the Marina, was appropriately celebrated. After a banquet, given by the Hastings and St. Leonards Electric Light Company, at which the Mayors of Hastings and Winchester and a number of other gentlemen were entertained, the invited company proceeded to the end of Hastings Pier, where the Mayor of Hastings formally switched on this long line of arc lights. The company then made a closer investigation of the lighting by driving along the sea-front.

For many years a certain amount of arc lighting has been done at Hastings by Brush continuous-current lamps, supplied in series from Brush dynamos, and the ordinary house lighting has been worked on the alternating-current transformer system. This practice entailed the use of two distinct sets of plant at the generating station, and rendered it impossible to combine the two loads, at least as far as the engines and dynamos were concerned. Upon the extension of the public lighting from the original 15 lamps, occupying little more than half a mile of sea front, to the present 52 lamps, extending some two and a half miles, it was very wisely determined to so arrange matters that the steady arc light load might be put on the same generators as would be used for the house supply, thereby materially improving the load factor and economy of the station. The work of carrying out these alterations and extensions was undertaken by the Brush Electrical Engineering Company, who have succeeded in turning out the work in an effective and thoroughly satisfactory manner. Contrary to the teachings of those who maintain that the continuous current arc invariably gives the best results in street lighting, the conditions on the sea front seem to be such as are favoured by the use of the alternate current arc. The light, which is thrown upwards, strikes pleasantly against the upper portions of the houses which skirt the sea front, and in this way an effect more generally resembling the even distribution of day light is produced.

Each lamp is fed from a separate transformer, this latter taking the primary power at 2,000 volts and transforming it down to 50 volts. A small choking coil placed in the lamp circuit serves to regulate the voltage on the arc. The transformers of the 52 lamps are grouped in parallel on two pairs of mains, the connections being so made that the failure of either main will extinguish only alternate lamps. These two mains are switched on to the station bus bars, being fed at 2,000 volts from the Mordey-Victoria alternators, which also supply the house mains. The alternators are rope-driven by Raworth steam engines. The contracting company have been ably assisted in carrying out this work by Mr M. G. Ross, the engineer and manager to the local company, and by Mr. E. Geipel, the resident outside engineer, and all parties connected with the enterprise are to be congratulated on this successful piece of work.

HEINRICH HERTZ.*

The first day of this year took away from us a fellow worker whose loss affects us most deeply. If, after a long career of discovery and a life rich in achievements, one of the old masters of science passes to his rest, we lament his death but we bow to the inexorable laws of nature. In Heinrich Hertz a discoverer of the first rank has been torn away from us in the middle of his work, and almost at the commencement of the prime of life. The sad news has spread far and wide, and so it is very fitting that we also should pay a tribute to his memory. Let us first glance over the development of the external events of his life during the short space of time allotted to it.†

Heinrich Rudolf Hertz was born at Hamburg on February 22, 1857, and was the eldest son of the then attorney (and later Senator) Hertz. His mother was a native of Frankfort-on-Main. After having attended a city school until his confirmation, he studied privately at home during the years 1873-4, and at Easter, 1874, he entered the highest class of the upper school of the Johanneum in his native town. At Easter, 1875, he left school, in his eighteenth year, with a certificate of fitness for the University.

Even as a boy he displayed great talent, but more especially a strong liking for, and an uncommonly great interest in, the exact sciences. As a scholar of twelve years of age he attended Sunday classes in geometrical drawing held at the Technical School. In addition to his scholastic studies he industriously practised the use of tools, and he went through that course of practical training in carpentry and lathe work which is of so great importance to the physicist; his skill enabled him to construct quite serviceable instruments from the simplest materials, and, among other things, he once made for himself a spectroscope.

* Memorial Address by Prof. Hermann Ebert, delivered at the meeting of the Physical Society of Erlangen, March 7, 1894. Translated by James L. Howard.

†For the following biographical notice the author acknowledges his deep indebtedness to Frau Prof. Hertz.

When he left the Gymnasium it became necessary for him to choose a profession. His desire to construct something useful and permanent and his innate modest temperament, which at that time caused him to doubt greatly his ability to accomplish anything satisfactory in pure science, as well as his newly awakened joy at the prospect of making a practical trial of his powers, all these led him to choose the profession of an engineer, and, indeed, that of a civil engineer. As a preparation for this calling he served during the year 1875-6 as an apprentice in the city engineer's office at Frankfort on Main, such preparation being at that time a necessary preliminary before entering the profession. After this he went during the Summer Semester of 1876 to the Technical High School at Dresden. During the twelve months subsequent to October 1876, his studies were interrupted by his year of military service, which he passed at Berlin in the Railway Regiment. In the autumn of 1877 he went to Munich. This was the most remarkable turning point in Hertz's career, which converted him from a man of practice to one of learning. Here he recognised that his nature could only find full satisfaction in dealing with science, and he applied himself in Munich specially to mathematics and physics.

After only a year, in the autumn of 1878, he removed to the University of Berlin, where he entered the laboratory of Von Helmholtz. His progress was unusually rapid. In 1879 he gained a prize offered by the Philosophical Faculty for a research on extra currents induced in coils and wires, a work which presented difficulties both of theory and experiment. In 1880 he graduated as doctor, and in the same year Von Helmholtz chose him as assistant in the Physical Institute, only three years after he had first devoted himself to the study of physics.

At Easter, 1883, when in his twenty sixth year, he became Privat Docent at Kiel, acting on the advice of Von Helmholtz and he immediately obtained a commission to teach theoretical physics from the Prussian Minister of Instruction. At Easter, 1885, when twenty eight years of age, he received a call as ordinary Professor of Physics at the Technical High School at Karlsruhe. From this place originated his epoch making experimental researches. In 1886 he married Elizabeth Doll, daughter of the Professor of Geodesy at the same High School.

When in the year 1887 death took away from Bonn Olausius, the founder of the mechanical theory of heat, there was no hesitation in conferring upon Hertz, although only thirty two years of age, the honour of succeeding a Clausius, and at Easter, 1889 he was called to Bonn.

Having thus succeeded to a secure and honourable position, respected and admired both in Germany and abroad, at an age when the powers of research usually first begins to make itself manifest, he was soon visited by the insidious enemy which was destined to bring so brilliant a career to such a tragic close. In the middle of the year 1892 a chronic blood poisoning, originating, probably, from a gathering in the jaw cavity, had already begun to undermine his hitherto excellent health. The crisis, which occurred in November, 1892, was passed by a successful operation, and he was able to continue his lectures throughout the Summer Semester of 1893, and (although with great efforts) until December 7th of the same year, only a short time before his decease. His malady then returned, and in a few weeks proved fatal; he died on New Year's Day in the 37th year of his age. According to the testimony of those who were near him and particularly of his wife, who nursed him faithfully to the last, his sufferings were indescribable. In him there passed away not only a man of great learning, but also a noble man, who had the singular good fortune to find many admirers, but none to hate or envy him; those who come into personal contact with him were struck by his modesty and charmed by his amiability. He was a true friend to his friends, a respected teacher to his students, who had begun to gather round him in numerous large numbers, some of them coming from great distances, and to his family he was a loving husband and father.

The course of events in the external life of Heinrich Hertz was simple and plain. But what a world is opened before us when we consider his scientific life, which was bound up within such narrow limits of time! To give a condensed sketch of its development is the object of the present address.

We generally speak only of his later epoch making researches as they alone have become known far and wide. But it is very instructive to glance once more over the earlier researches from the higher standpoint reached by the later ones. Further, we perceive how the later discoveries which have transformed the whole subject, were originated and developed from the former, these being in a certain restricted sense stepping stones to the latter series of experiments, for Hertz was not led by mere accident to his investigations on the propagation of electric waves; it was a comprehensive and well arranged process of argument which was crowned by these researches, even if a happy chance often furnished him with the means of more quickly reaching the goal. I shall confine myself to the electrical researches and therefore merely mention Hertz's work on the evaporation of liquids and in particular of mercury in vacuo, on the pressure of saturated mercury vapour, his meteorological investigations, his researches connected with [illegible] the theory of solids; these all show the [illegible] work.

His scientific activity began as we have already seen, with the solution of a prize problem. The research proposed by the Faculty of the University of Friedrich Wilhelm at Berlin for the year 1879 was the experimental investigation of the induced electric currents. The problem, the solution of which was intended to be advanced by this research, was [illegible] the other theories of electric phenomena [illegible]. These theories were based on the assumption that [illegible] fluid which moved through the conductor [illegible] thing of the nature of matter was as concerned in electric [illegible] this hypothetical something must possess [illegible] small degree. If it had mass it must possess inertia [illegible] jected to "electromotive forces," and [illegible] set in motion, contain a certain amount of kinetic energy [illegible] of its mass and velocity. This kinetic energy would manifest [illegible] if the current in a coil were alternately suddenly made and interrupted, because "extra currents" are then set up in the [illegible] consequence of the mutual inductive action of the separate parts on each other, and the energy of these extra currents would be present that of the moving electrical masses. An exact [illegible] estimate of this energy, and hence of the quantity of electricity, say, in a cubic millimetre of a wire traversed by a current, was hardly to be expected because of the difficulty attending the measurements; one had to be content with seeking an upper limit for the quantity of energy and thus furnishing an answer to the question how great can this quantity of energy possibly be?

The first considerable experimental investigation of Hertz was devoted to this problem. It appeared with the title "Experiments to determine an Upper Limit for the Kinetic Energy of an Electric Current." The result of the experiments was negative, since the upper limit became smaller and smaller the more exactly the experiments were performed. It was necessary to conclude that the quantity looked for would eventually become zero if all errors of experiment could be successfully eliminated. But it was certainly a matter of great importance for Hertz that in his first research the domain of electricity he already convinced himself that assumptions as to the material nature of electricity were untenable, and that the postulated fluid vanished just as he sought to [illegible] with more accurate means of observation.

In this first work, published when he was only twenty six years of age, great experimental skill was displayed. We find him working with long stretched wires and large wire rectangles which he stretches in the cellar of the laboratory, pieces of apparatus which he was destined to use later in such a masterly fashion as he [illegible]. One particularly clever device was the arrangement of a [illegible] tator by the simple rotation of which a complicated system of conductors could be automatically and quickly inserted in the [illegible] cut out or reversed, in regular order. That Hertz was a master of the mathematical theory, the most important [illegible] his work, is shown by the calculation of the [illegible] turns and layers in such a way that [illegible] the self induction of [illegible].

Hertz returned [illegible] Upper Limit [illegible] when he employed a [illegible] more sensitive, but [illegible] very thin silver tube [illegible] a strong current in the [illegible] ing to the older theory, the [illegible] cubic millimetre of silver, was in this case as great as possible. In this moving electricity was only subject to the electromotive force of the voltaic cell [illegible], the plate was traversed [illegible] symmetrically from anode to cathode, and [illegible] a sensitive galvanometer [illegible] perpendicular [illegible] between these wires. The plate was now [illegible] and rapidly rotated about an axis through its centre perpendicular to its plane. If moving electricity possessed any property [illegible] alogous to inertia the current would be deflected by this rotation out of its original path, just as [illegible] surface of the earth from the east to the [illegible] its rotation from their south to north direction and strike the [illegible] at an angle. In this case a component of the current would flow between the two transverse electrodes, and this would be [illegible] by the galvanometer, even though only small [illegible]. Numerous sources of error, thermal currents caused by unequal heating of the electrodes by the air currents, alterations in the rotating plate due to centrifugal force, &c., all these were encountered and to some extent masked the effect looked for. But Hertz knew how to reduce these sources of error to a minimum by a judicious combination of separate experiments under varying conditions. In spite of this, 2500 separate observations failed to give any positive result. The upper limit so determined is that the kinetic energy of an electric current whose density [illegible] electromagnetically [illegible]

unity is, per cubic millimetre of a silver film, not so great as that of $\frac{1}{10000}$th of a milligram moving at the rate of a millimetre per second. At the end of this Paper he points to the possibility of obtaining positive results in the case of electrolytes, in which the motion of the electricity is bound up with that of the material ions. This conjecture of Hertz has been confirmed by later researches of Colley and Pescoudres. Here, however, it is not the inertia of electricity itself, but that of the bodies carrying it, by which the phenomena are brought about.

His thesis for the degree of Doctor in 1880 treats of induction in rotating spherical conductors or hollow spheres between magnets according to the theory of Neumann.

(To be continued.)

DIRECT-READING APPARATUS FOR THE DETERMINATION OF THE MAGNETIC QUALITIES OF IRON.*

BY DR. A. KOEPSEL.

The author, who is the designer of the apparatus described, having set out with the idea that for a direct reading instrument an incomplete magnetic circuit must necessarily be employed, began by the investigation of two points: first, whether results could be obtained with an incomplete magnetic circuit which could

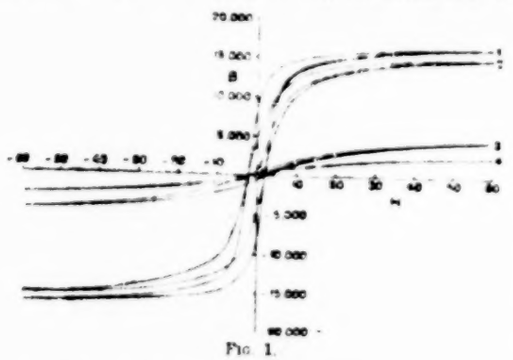

FIG. 1.

be definitely referred to those obtainable with a closed circuit, so that the latter could be easily deduced from the former; and, secondly, whereabouts in an incomplete circuit is the best position for the division, with the object in view of getting the magnetisation curves as correctly as possible. A division in the sample itself was found to be out of the question, as even when the pieces were pressed tightly together a considerable alteration of the curve of magnetisation was observed. Fig. 1 shows in curves 1-4 the

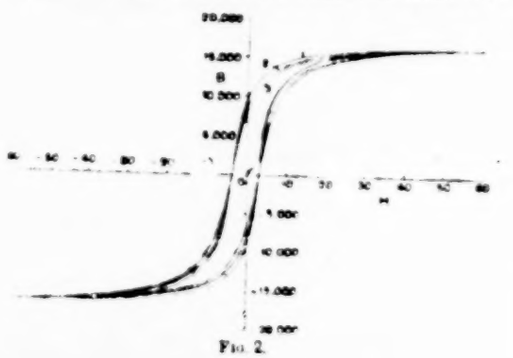

FIG. 2.

curves of magnetisation obtained by the ballistic method from a bar of soft iron 6mm. in diameter, the return being by a large yoke, the curves referring to the following cases:—(1) The bar whole and undivided; (2) The bar cut in two, and the surfaces pressed tightly together; (3) The surfaces 1·3mm. apart; (4) The surfaces 2·8mm. apart.

On the other hand, a division in the yoke itself had comparatively little effect, as shown in Fig. 2, curves 1-3, which represent the curves of magnetisation of a similar bar under the following conditions. (1) With an undivided yoke. (2) Yoke divided, the surfaces pressed tightly together. (3) The surfaces 1mm. apart. As the yoke had 100 times the surface of the sample, the magnetic resistance of the division was 100 times as small as in the former case. It is then of great importance to get the yoke as large as possible, which was done in the author's case by making the yoke a surface of rotation, which one can imagine formed by rotating the yoke

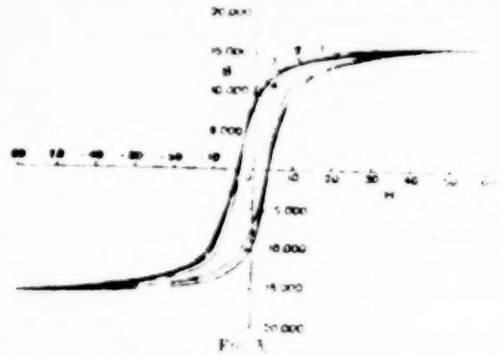

FIG. 3.

about the test bar as an axis, the bar and the magnetising coil being thus completely enclosed. It was then found that, although the curve obtained by pressing the half cylinders together (No. 2, Fig. 3) was not the same as that obtained with an undivided yoke (No. 1), yet the latter could be obtained from the former by the shearing process; and, further, the experiments showed that a gap of 1·8mm. between the cylinders did not very much alter the form and position of the curves (Nos. 3 and 4).

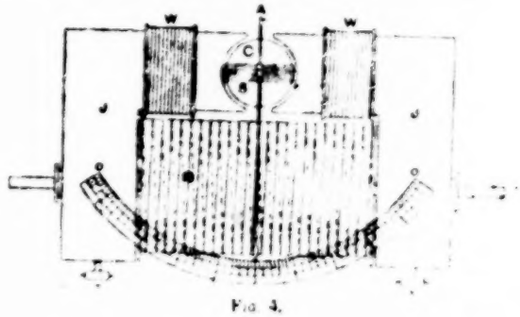

FIG. 4.

A gap of 5mm., however, was enough to afford room for a flat wound coil carrying a current and controlled by a torsion head, the amount of whose rotation to bring the coil to zero is a measure of the field. This coil, however, had to be made very small, and had, consequently, a very small torque; and therefore a design had to be evolved which, while not increasing the air space, should allow of a larger area of coil. This object was attained by return

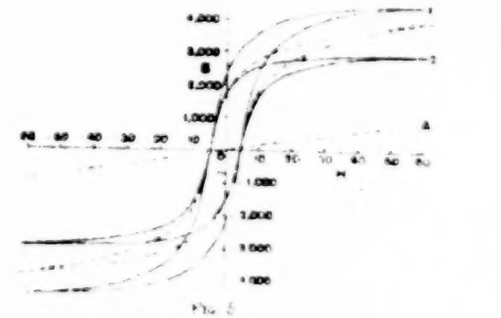

FIG. 5.

ing to the simple form of yoke shown in Fig. 4. The yoke J is bored out at A like the pole pieces of a dynamo, and the piece bored out is replaced by a soft iron cylinder, C, having a diameter 2mm. less, and in the cylindrical air space so made a coil is placed, working on pivots, and capable of rotation, and which is traversed by a current of about 0·01 ampere led in by palladium springs. The openings oo of the yoke serve for the introduction of the

The explanation of the results obtained appears to be that when the cables are charged with positive electricity the polarisation produced is sufficient during the time of one alternation to considerably increase the resistance of the slight leakage to earth by the formation, probably, of a film of oxides; this obstruction is cleared off by the succeeding wave of negative charge, which, as is well understood, opens the leak. The time of an alternation is however, quite insufficient to produce any such effect on the water pipe earth, and, in consequence, the net result is a passage of negative electricity to earth through the cables, and of the corresponding positive quantity to earth by the water-pipes.

The maximum effect that has been observed so far amounts to an apparent E.M.F. slightly exceeding 10 volts, with the eleven circuits connected to one machine; but it appears that a greater effect would be produced by still further increasing the length of mains in connection.

HEINRICH HERTZ.*

(*Continued from page 274.*)

In 1881 we already find him investigating electrical equations which do not belong to the older theories. An interesting Paper written at this time is "On the Distribution of Electricity on the Surface of Bodies in Motion." The theory of action at a distance shows that in every electrically-charged body at rest the charge resides wholly on the surface, so that the interior of a hollow sphere is quite free from any trace of the hypothetical fluid, and throughout the whole conductor the electric potential has everywhere the same value, even in the interior of the mass of the conductor. Hertz asks himself, "What happens if bodies so charged are moved towards each other?" The distribution of electricity on the surface must at any instant be quite different from that on the surface of bodies at rest, even if these could be brought to exactly the same position in space as the moving conductor momentarily occupies; further, the potential is now no longer constant, either on the surface or in the interior of the body, and whereas a hollow metallic conductor at rest completely screens its interior from external electrical forces, this is no longer the case when the conductor is in motion. Currents are set up in its interior, and along with them heat is developed, resulting in an apparent loss of energy. Continuous motion of charged bodies can therefore only be kept up by supplying external work.

Hertz developed very skilfully the formulæ for these cases, and the general formulæ of electrostatics are greatly extended by them. He applied the general solutions to the specially important cases of a solid of revolution rotating in an electric field with constant velocity about an axis, and particularly considered solid and hollow spheres and cylinders. In the latter, even in a uniform field, electric currents are set up which are deflected in a singular fashion by the rotatory motion; inductive effects act through the metallic body upon its interior, so that it no longer behaves as a perfect screen, and so on. In connection with this Hertz arranged an experiment. Over a horizontal and only moderately good-conducting glass plate a needle, provided at its ends with horizontal metallic plates, is suspended by a metal wire. As soon as these plates are charged so that they become electric poles their oscillations becomes greatly damped. The phenomenon is analogous to the damping of a swinging magnetic needle which excites opposing induction currrents in a copper conductor surrounding it. In this work we find the following significant passage:—"If an electric pole be moved at a constant distance above a flat plate the electrification, when once excited, follows it, and the simplest and, indeed, the usual explanation is that the electricity, supposed material, is the thing which moves, but we reject this hypothesis." We here see Hertz already freeing himself from the "usual explanations."

In the year 1883 he devoted his attention to a group of phenomena which always interested him, namely, electrical discharges in gases. In his first work on this subject, "On a Phenomenon accompanying Electric Discharge," he describes some singular luminous rays and cloud-like or arborescent appearances observed when the electrical discharge from an induction coil is allowed to pass out of a tube into a mass of gas which is not too highly rarefied; the positive electrode was inside the tube and the negative one near its mouth. The experiments were greatly varied, and the description of them, although only eight pages long, is full of detail.

To the same year belong the "Researches on the Glow-Discharge," which were carried out in Berlin, although the Paper is dated from Kiel. At that time there existed but three methods for the production and study of the phenomena of electric discharges as they occur in rarefied gases; namely, the influence machine, the induction coil and large voltaic cells of high electromotive force. Of these Hertz chose the third, and constructed a secondary battery with 1,000 pairs of lead plates, enabling him to obtain an electromotive force equal to that of 1,500 Daniell cells in series. The current yielded by it was led by wires into discharge vessels of various shapes. Hertz observed more especially the luminous appearances near the cathode with high vacua.

Here it is the rays of the glow discharge and the cathode rays, which are certainly related to them, concerning which Hertz's work discloses many important facts, although he was not able to entirely lift the veil from them. Apparently this was not possible except from his higher point of view attained through the later researches, namely, that of the doctrine of electric oscillations and waves. Even here we find occasional mention of electrical waves and of electrical movements which are propagated through a medium like waves; but the ideas are not yet so clear as they came to be eventually by reason of the later striking experiments.

The first part of the Paper is devoted to an old and much debated question, "Are the discharges through a rarefied gas continuous or discontinuous? Are they still discontinuous in the particular case considered here, when we apply to the gas an apparently continuous battery current?"

Hertz endeavours by ingenious arrangements to prove that his discharges are continuous. On looking over the lines of the argument, however, it is seen that they are only able to establish a lower limit to the number of separate discharges in a second. Whether discontinuities of very high frequency occur or not cannot be definitely decided by the method used, a fact of which Hertz himself was quite aware. If we consider the phenomena after assuming the existence of oscillations, evidence for which is furnished by the striation of the luminous column, thus rendering it analogous to the interference phenomena of a periodically varying source, a distance of 1·6cm. between the striæ, which is easily obtained, would correspond to a wave length of 3 cm. From Hertz's later investigations we know that this represents an electric disturbance, with a frequency of 10,000 million per second. Fluctuations with such high frequencies were no longer observable by the method used, since they do not obey the ordinary laws of electric currents, as was shown by Hertz's later work. I cannot here enter into details concerning the experiments. It would appear that his proof had not satisfied him on this point, for at the end of the Paper referred to he suggests the intermediate assumption, according to which the flow of electricity through a gas is, on the whole, continuous, but that in the tube itself electrical motions of an oscillatory character may be superposed on the constant current, a view which is rendered even more tenable by more recent investigation.

He likewise considered the very important question of the course of the stream lines in a gas traversed by electric discharges. A necessary introduction to this was the proof that cathode rays do not deflect a magnet, although they are deflected by it. It appeared, further, that the cathode rays do not indicate the path of the discharge, but are set up in the course of the discharge, and then obey definite laws of propagation. Experiments upon the absorption of cathode rays were indicated, which have since led to a series of beautiful experiments by Philipp Lenard.

In the last part of this Paper he shows, among other things, that the cathode rays do not exert any electrostatic action, and that they certainly cannot be regarded as electrified particles shot out from the cathode, although many physicists often adhere to and express this view.

I should like to refer to the experiments here described concerning the peculiar property of cathode rays, that of bringing about the equalisation of electric potential in a direction transverse to them, and so promoting "transverse discharges," experiments which have been extended by other observers. This behaviour of cathode rays reminds us of a quite analogous property of light waves, discovered by Hertz; namely, that the ultra-violet waves possess the same equalising power in a high degree.

The general results of the work can be better understood when it is stated that they support a view expressed in similar form by other observers, for example, E. Wiedemann and Goldstein, namely, that the cathode rays consist of a certain form of ether-motion more nearly allied to light than to any other natural agent, and that they are set up by electrical actions, but afterwards constitute an independent phenomenon, just like the light sent out from an electric lamp.

* Memorial Address by Prof. Hermann Ebert, delivered at the meeting of the Physical Society of Erlangen, March 7, 1894. Translated by James L. Howard.

Transmission of Pictures by Electric Current.—M. Bertillon, the inventor of the anthropometrical system of identification adopted by the Paris police, is endeavouring to revive the use of the picture telegraph, as he thinks that it would be of the greatest service in rapidly transmitting and disseminating the portraits of suspected Anarchists and other criminals.

fully into the question, and arrives at the conclusion that the image measured in this way is 1¼ times the true diameter of the pupil, and thus shows that it is necessary to multiply the measurement actually obtained by ⅘ in order to get the true result. When this correction is made these pupillometers give a perfectly accurate result. They are simple in construction and rapid in action. The errors arising from parallax and from confusing the border of the iris with the pupil, which are so serious in most pupillometers, are entirely overcome in this.

The simplest form employed in the author's experiments was one due to Robert-Houdin, and is illustrated in Fig 2. It consists of a shallow copper cylinder 12 millimetres deep, the front being provided with an opening and a small hole, *b*. A screen pierced with a small hole, *a*, and provided with an index, *c*, slides over this opening by turning about an axis, *d*, in the circumference of the circle. The distance between the two holes *a* and *b* can be read off on the scale by the index *c*. All lateral light can be shut off by the use of a dark cloth. Other instruments have been devised on the same principle. One due to Gorham consists of a metal tube closed at one end with the exception of a radial opening. A metal disc pierced with holes arranged radially in pairs at various distances apart is attached at the closed end of the tube in such a manner that it can be turned so as to present different sectors to the radial opening at the end of the tube. In this manner, by looking along the tube and turning the disc, two bright spots of light are seen, and the distance apart of the spots seen can be regulated by simply turning the disc. When two of the holes are such that the circles of diffusion touch each other, it is known that the distance

Fig. 2.

apart of these holes is equal to the diameter of the pupil. M Gorham proposed to use this instrument as a photometer by measuring the size of the pupil when the tube is turned towards different lights. The distances of the lights were adjusted till the diameter of the pupil was the same whichever light was looked at, and it was assumed that under these circumstances the square of the ratio of the distances was equal to the relative candle-power of the lights. This assumption is, however, doubtful, as the contraction of the pupil does not depend merely on the intensity of the illumination. Before concluding the account of the various pupillometers yet devised the method of photographic records used in 1887 by Beliarminoff must not be forgotten. This scientist used a chronophotographic apparatus, by means of which the diameter of the pupil could be ascertained at any instant during the course of the tests. This method undoubtedly is the most accurate, but it is too complicated and costly for use.

As regards the direct action of light upon the iris, some experiments made by Brown Sequard in 1847 appear to prove that only the luminous rays have any effect, heat rays and chemical rays being inactive. The eyes experimented upon were those of fish and batracians. They were extracted from the orbits immediately after death, and the pupils were found to contract on the approach of a candle, and to expand again in the dark, the effects being reproducible some times as frequently as 100 times in an hour. The interposition of a plate of alum did not alter these effects, showing they were not the result of heat rays. The persistence of the pupil movements, long after the nerves had lost all sensitiveness to irritation, seemed to prove that the action was muscular and not nervous. Moreover, utilising the fact discovered by Brücke that the cornea and crystalline of the ox and the rabbit absorb the violet and ultra-violet rays, light was allowed to fall on the eyes of frogs after having been previously filtered by passing through the eye of a rabbit. The pupillary contraction was found to take place just as before. All the evidence is thus in favour of the view that only the luminous rays are capable of producing the movements of the iris. Experiments of a like nature on human eyes are however, still wanting, and it is to be hoped that some will before long be made.

Actual measurements of the diameter of the pupil of the eye have been very rarely made. Lambert, in his book on photometry published during the last century, gives a few measurements and conclusions founded on them. The principal of these conclusions is that if the eye be exposed to different degrees of illumination, the area of the pupil exposed does not vary inversely as the illumination, but in such a manner that the product of the illumination and the area exposed becomes less and less the feebler the illumination. M. Charles Henry is trying to reproduce these experimental results of Lambert with better and more reliable apparatus.

HEINRICH HERTZ.*

(*Continued from page 299.*)

The last research carried out in Berlin is entitled "On the Behaviour of Benzine as an Insulator and Absorber." All insulating materials exhibit in a greater or less degree the often very troublesome property of absorbing and retaining a portion of the electric potential acting upon them. In the older theories this process of "absorption" is represented by assuming that the electricity partially wanders from the charged condenser plates into the insulating material between them, and is there retained. But it was soon observed that the property of absorption is essentially connected with want of homogeneity of material, so that homogeneous crystals, for example, exhibit the phenomenon only in a small degree. In order to obtain more definite results Hertz undertook experiments with liquids which can easily be rendered perfectly homogeneous, and he found in commercial benzine a medium which insulated sufficiently well for his purpose. It then appeared that the dielectric power of benzine increased under the continued action of electric forces. The cause of this was traced to the increase in the amount of suspended or dissolved impurities which were set free; under the influence of electric charges, therefore, the liquid is "electrically cleaned." It was evident, also, that the power of absorption decreased after this prolonged cleaning, so that this property must really be attributed to want of homogeneity. No migration of free electricity takes place, but the electric stress takes hold of the separate foreign particles embedded in the medium, and arranges them in a sort of strained or polarised condition. Hertz showed that this was the case by suddenly letting the liquid flow out of the trough which he had used as a condenser in these experiments, or by lowering into it two metallic plates connected with an electrometer, which clearly indicated the presence of this polarised state in the medium.

Although somewhat anticipating its chronological order I will here mention a short communication "On the Dimensions of a Magnetic Pole in Different Systems of Units," in which Hertz shows, although quite objectively, in the then burning question of the dimensions which should be chosen for electric units. He shows that the so-called "electro-magnetic system" is not more justifiable than the "electrostatic system," simply because it does not lead to want of agreement between the theories of Maxwell and Clausius; he then points out the cause of this want of agreement, and shows that the ratio of units in the two theories is exactly inverted if the magnetic measure of the current is taken as a starting point instead of the electric one.

We come now to the unique and splendid theoretical investigation of the year 1884, which is certainly the most important one in connection with the further development of Hertz's ideas, namely "On the Relations between Maxwell's Fundamental Equations of Electrodynamics and those of Opposed Theories." We may characterise this as Hertz's greatest contribution to theoretical physics.

As the title itself indicates Hertz now declares himself definitely opposed to the orthodox theories of electric phenomena which at that time were put forward in Germany, and he passes over to the camp of Maxwell's followers. But why does he take this step? He

* Memorial Address by Prof. Hermann Ebert, delivered at the meeting of the Physical Society of Erlangen, March 7, 1894. Translated by James L. Howard.

was not attracted by the fact that in Maxwell's theory at that time the part which explained light as an electro-magnetic phenomenon was still shrouded with a certain degree of mystery. He was not allured by the wide perspective and the multitude of new problems towards the solution of which a researching mind would be attracted; no, it was after a prolonged struggle with his inward conviction that he freed himself from the old ideas which had become fast rooted even in him. He proved, firstly, that the systems of equations of the older theories are incomplete, that from their certain members are missing, the absence of which leaves a supporter of the theory at disadvantage would concede to be a defect. But if these terms are added the formulæ begin to be unwieldy and awkward, in place of finite expressions we have infinite series which certainly converge towards a finite limit, but which appear so opposed to nature that the dissatisfaction on arriving at such formulæ is not compensated by the fact that we at last possess the complete expressions for the observed phenomena. Hertz then deduces from the unwieldy formulæ a system of equations of great symmetry and simplicity, a system in which is immediately detected as a known one in Maxwell's theory. The necessary improvement in the older theories leads, therefore, to that of Maxwell, and this must be chosen as the starting point in all further progress. But even Maxwell's formulæ are here expressed in a new form, and this is an important advance in the theory. Maxwell, free as he was, could not completely emancipate himself from the older views, and his formulæ possess a slight awkwardness and want of simplicity, traceable to the fact that the fundamental ideas of his theory is not yet logically and clearly expressed by them; they still retain traces of conceptions belonging to the older systems and ordinary conceptions, as Hertz occasionally and significantly calls them. Hertz has definitely removed these ordinary notions, thus clearly exhibiting the kernel of Maxwell's theory. Already in this Paper of 1884 we meet with that system of six partial differential equations which served afterwards as Hertz's guide along the tedious and devious path of his experimental researches.

Hertz had thus acquired new views from his theoretical considerations, and with this discovery in theory his life work was indicated for him. He must now strive to prove experimentally the superiority of Maxwell's theory and to trace all the immediate consequences of it. That the task of finding out the best method was no easy one even for a Hertz we may infer from the fact that he was occupied during three years merely in preparing the necessary apparatus.

One of the most important consequences of Maxwell's theory was that disturbances of electrical equilibrium produced at any place must be propagated as waves through space with definite velocity, and, with the velocity of light. This was plainly a fact to work upon. If this propagation was to be traced through, the successive elaboration by the disturbances must be rapid, and if a definite effect was to be observed they must also follow each other at regular intervals; that is, periodically varying electrical conditions, or electric oscillations must be set up, the period of which would have to be very small so that the corresponding wave length, taking into account the extraordinarily high velocity of propagation, should be only a few decimetres.

The method of exciting electrical oscillations was indeed known, and that of producing rapid electric disturbances had already been investigated in Helmholtz's laboratory. As far back as 1870 Von Bezold had actually measured the length of electric waves and observed their interference in wires, and yet some links in the chain were wanting. One, or rather two, further conditions were necessary. We are fortunate in possessing Hertz's own account of the original his epoch-making work. In the introductory notice to his collected Papers on electric waves* he gives a classically beautiful picture of the gradual advance of a genius in research, in which his modesty compels him to omit much that we ourselves must fill in, namely, the importance of his earlier work.

He tells us that his interest in electrical oscillations was originally awakened by the Berlin prize of 1879, which was to be awarded for an experimental proof of a relation between electrodynamic forces and dielectric polarisation in insulators. Prof. von Helmholtz advised young Hertz to dedicate himself to this research. Hertz answered, however, that the then known oscillations were too slow to ensure success, and he therefore gave up the research, but from that time he was on the look out for everything connected with electrical oscillations. Consequently he immediately recognised the importance for his purpose of an observation which in itself appeared very trivial. One of those accidents occurred which often point the inquiring observer to the right path and lead to important consequences. Hertz tells the story himself very neatly. In the collection of physical apparatus at Karlsruhe he found an old pair of so-called Riess's or Knochenhauer's spirals, short, flat coils of insulated wire, with the turns all in the same plane. Hertz showed them in lecture and performed experiments with them. He there

* "Electric Waves," by H. Hertz, translated by D. E. Jones. Page 1. Macmillan.

upon noticed that the [illegible] small induction coil, [illegible] inside [illegible] inserted in the circuit of the [illegible] covery of the "electric spark gap" [illegible] ntative measurements possible. [illegible] previously been somewhat [illegible] above all that a very [illegible] experiments in which sparks played [illegible] upon as "impure" and [illegible] distance of time, provided only the discharges for example, must [illegible] small capacity, the paths of the discharge were of simple form and consisting of [illegible] short wire, or the [illegible] distance were fulfilled, in general, [illegible] electrical [illegible] We have here the real kernel of Hertz's work, and [illegible] sum up the experimental evidence of all [illegible] following sentences:

1. If we allow small condensers with small [illegible] through short and simply constituted circuit [illegible] long spark gap, we obtain a sharply defined discharge of very [illegible] duration, which is the long sought for [illegible] trical equilibrium. This was a discovery which [illegible] by no theory a nearly [illegible] which, however, all the later work depends. [illegible] further that at the same time success was [illegible] point, since at most of the reported [illegible] that Hertz had a [illegible] of the [illegible]

2. Such [illegible] circuit of [illegible] even when the two circuits are separated from each other [illegible] distances. Hertz had therefore [illegible] which he could detect the waves produced by the exciter [illegible] pagated to any distance.

In the work which now appeared, "On very Rapid Electric [illegible] latter, we find him occupied with these [illegible] studying his apparatus, and gradually [illegible] [illegible] As an exciter of oscillations he uses [illegible] metal rods, to the ends of which metal [illegible] connected. The exciter is backed in the middle by a [illegible] with small spherical knobs between which [illegible] exciter is charged by an induction coil [illegible] whose discharge only plays a secondary [illegible] intermediation. The resonators [illegible] are, likewise provided with [illegible] that they show the most distinct resonance [illegible] they are "electrically tuned." When a resonator [illegible] up in them, sparks pass across the gap, and the greatest [illegible] the spark measures the intensity of the effect.

Such is the principle of the new and simple means which [illegible] has introduced into the physical laboratory, and which [illegible] physicists are at present working in various directions, [illegible] endeavouring to penetrate into the unknown. It was [illegible] strange accidental circumstance that the discovering [illegible] later work of Hertz met with immediate recognition rather [illegible] to their intrinsic value. How often the greatest discoveries [illegible] long unheeded. Hertz found in his earlier experiments [illegible] resonance phenomenon which attracted his [illegible] ness and singularity and characteristic [illegible] to splendid character. [illegible] of the resonator sparks were [illegible] the primary circuit. If the latter [illegible] spark gap they appeared small and hardly [illegible] came considerably larger and [illegible] between the two spark gaps. [illegible] Later [illegible] light on this [illegible] drama crash on [illegible] year [illegible] came to the conclusion that this singular [illegible] is traceable only to ultra-violet [illegible] M[illegible] termed these researches and discoveries [illegible] experimental physics that [illegible] these experiments did not [illegible] closer relation between [illegible] Hertz popular, so that everything [illegible] read.

For people, however, the [illegible] though only subsidiary, [illegible] we were on the track of [illegible] electric oscillations. We [illegible] Hertz [illegible] ratus. In the following [illegible] linear Electric Oscillations [illegible] most difficult and the most important of [illegible] searches; it is often [illegible] it forms a necessary step to the following [illegible] become familiar with the phenomenon [illegible]

to deal with the propagation of oscillations through space. The apparatus was already furnished; as exciter he made use of a straight metal rod with a spark-gap in the middle and a spherical conductor at each end to give it capacity. When sparks pass rapid electrical surgings occur; we have a rectilinear oscillation whose effect is radiated out into surrounding space. As receivers he used tuned circles of wire, likewise provided with very small spark-gaps whose length could be measured with a micrometer. These were brought into all kinds of positions with respect to the exciter, and Hertz studied and measured the effects. These effects were very different at different points in the neighbourhood and in the various positions of the receiver, but a law was soon found to apply to them. "The discovery and disentanglement of these extremely regular phenomena gave me peculiar pleasure," says Hertz. By an argument which was ingenious, though simple in its results and indisputably clear throughout, he established in each case how the electrical radiation must act at the different points in the neighbourhood of the oscillation, in order to produce the observed effect on the receiver, and he finally succeeded in giving a clear and intelligible account of the propagation of the radiation through space. Many remarkable phenomena then presented themselves, of which the older theories could offer no explanation. In the same year, 1888, he showed in his Paper on "The Forces of Electric Oscillations, treated according to Maxwell's Theory," that this theory gives exactly the same distribution of forces as his experiments had yielded, with all their peculiarities and apparent anomalies. Hertz set out in this Paper from the simplified form of Maxwell's theory which he had established in 1884.

Great discoveries now followed one after another, each representing a new triumph of Maxwell's theory, and, above all, of the newer views. The papers which were presented to the Berlin Academy between November 10, 1887, and December 13, 1888, mark a new era.

The Berlin prize problem now received a definite solution in the research "On Induction Phenomena produced by Electric Disturbances in Insulators." It was shown that "alternating conditions of electric stress or dielectric polarisation" produce electro-dynamic action and inductive effects, analogous to those set up in a conductor by a rising or decaying voltaic current. The older theories had for the most part disregarded the intervening medium, according to them the effect travelled directly across it, whereas Maxwell's theory had these electro-dynamic actions as one of its most important consequences. At the same time the old controversy concerning the action of "unclosed circuits" was set at rest.

Three months later appeared the Paper "On the Velocity of Propagation of Electro-dynamic Actions." In this research an experimental proof was given of the fact that electro-dynamic actions are propagated through space with finite velocity. For the velocity of electric waves in air a quantity of the same order as the velocity of light was obtained. For the velocity of propagation along stretched wires he found a value different from that in air; theory required them to be the same. In consequence of an error in calculation the velocity of waves in wires was found smaller than the velocity of light. But he here showed himself an unbiassed lover of truth. Although convinced of the truth of the theory he submitted his actual results, and confessed that he had here met with an unavoidable difficulty. Let us quote his own words on the subject, written four years later in the introduction to his book after he had explained the discrepancy:—"I have described these results in great detail because I wished to convince the reader that I was not merely endeavouring in this research to support a preconceived opinion by the most convenient and suitable interpretation of experiment. On the other hand, I have carried out the experiments, which in themselves were not easy, with the greatest possible care in the face of a preconceived opinion. And yet, with all my good fortune, I have had decided misfortune just in this experiment. For, instead of reaching the true result with small trouble, which a properly arranged plan would probably have enabled me to do, I have apparently taken great pains, and fallen into error."

It was not discovered until later that the deviations from the theory were caused simply by the walls of the room, which reflected the electric waves impinging on them. Edouard Sarasin and De la Rive have finely shown that the velocity of propagation in wires has the same value as in air, each being that of light, by repeating Hertz's experiments on a large scale, and with every precaution, in the large machine shop of the Geneva Waterworks. The result is therefore quite decided for us now; but the disturbances which crept into Hertz's own experiments have given us a proof of his extraordinary acuteness.

The account of the research "On Electro-dynamic Waves and their Reflection" was published in the same year. Although Hertz had hitherto only succeeded in working with waves propagated along wires, he now demonstrated the existence of similar waves in free space. Opposite the radiator a large screen of zinc plate, with a plate suspended on the wall, the electric waves emitted from the radiator were reflected from this plate and in front of the direct waves interference phenomena were produced, consisting of stationary waves with nodes and loops. When, therefore, Hertz moved the circle of wire which served as a receiver to and fro between the screen and the radiator the sparks in the receiver circuit disappeared at certain points, reappeared at other points, disappeared again, and so on. Thus there was found a periodically alternating effect corresponding to nodes and loops of electric radiation, showing clearly that in this case also the radiation was of an undulatory character, and the velocity of its propagation finite.

In the Paper "On the Propagation of Electric Waves along Wires" he shows that alternating electrical movements with frequencies as great as those under consideration (about a hundred million per second) are confined to the surface of the conductor along which they are propagated, and do not penetrate into its interior. This is a very important experimental confirmation of a theory of Poynting, founded upon the ideas of Faraday and Maxwell, concerning electric currents. According to this theory an electric current is a phenomenon which has its seat in the region outside the wire conveying it rather than in the interior of the wire. The magnetic effect of a current shews us that something goes on in this outside space which is very closely connected with the passage of the current. We are not to look for something flowing along the wire, but must rather consider that the energy enters the wire from without, and is thereupon converted into the special form of heat. It is thus not the copper core of a cable which conveys the energy from the sending to the receiving station, but the insulating layers surrounding the core; the terms "conductor" and "non-conductor" exactly change places. It is certainly true, as Hertz very pointedly remarks, that this apparent paradox only arises because we neglect to state what we mean by the term *conduction*. In reality the electric fluid of the older theories is abolished, in its stead have been introduced electric and magnetic forces existing independently in space, and advancing through it, carrying their energy with them, and for these the circumstances of conductivity are exactly the inverse of those for the hypothetical electric fluids.

In the course of his experiments Hertz had learned the method of producing, and working with, very short electric waves of 26cm. length. The oscillations corresponding to them could be collected by a concave cylindrical mirror and concentrated into a single beam of electric radiation. According to Maxwell's electro magnetic theory of the phenomena of light such a beam must behave like a beam of light. That this is the case was shown by Hertz in his Paper "On Electric Radiation," the communication which has become the most popular one, and has created the greatest astonishment far and wide. The modest man says, in the introduction to his collected Papers, "These experiments succeeded each other quickly, and without any difficulty. The experiments with the cylindrical mirrors soon attracted notice, and they have been often repeated and verified. They have met with an approval quite beyond my expectation."

He showed how such electric radiation was propagated in straight lines like light, that it could not pass through metals, but was reflected by them; that, on the other hand, it was able to penetrate through wooden doors and stone walls; he also proved, by setting up metallic screens, that a space existed behind them in which no electric action could be detected, producing in this way electric shadows; and, by passing the rays through a wire grating, he succeeded in polarising them, just as light is polarised by passage through a Nicol prism. But the most striking experiment was that in which he directed the electric ray on a large pitch prism, weighing about 12cwt., the ray was deviated, being refracted like a ray of light in a glass prism. Thus he gave to the whole its finishing touch, and the edifice was now completed.

In the communication which appeared three years later and this was dated from Bonn, "On the Mechanical Effects of Electric Waves in Wires," he demonstrated that not only does a wave of changes of electric state travel from the radiator through space with the velocity of light, but that along with it and inseparable from it there exists a magnetic wave, as theory requires.

In his last experimental work he finally returns to the phenomena of discharge in gases and shows also at the same time, as Wiedemann and Ebert, that cathode rays do pass through thin films of metal, but are stopped by a dielectric film, no matter how thin it may be.

And now inexorable death sets a limit to the further progress of the clever experimenter. We are indebted to him for many other Papers of a theoretical character, as on the fundamental equations of Electro-dynamics in Bodies at Rest and on Maxwell's theory, a great advance in the mathematical theory of electric and magnetic phenomena.

On his finished but unpublished work, on the Principles of Mechanics, to the early appearance of which the scientific world looks forward with intense interest,

Let us cite once more in proof of [illegible]

[illegible]

at a distance, and concerning electrical and magnetic effects he has shown that they are propagated from particle to particle through space with finite velocity. This is a result of great and general, one might almost say philosophical significance. The mysterious darkness which surrounded those secret distance actions of former times has been cleared away; the dogma, honoured by science until now although unwillingly tolerated by reason, that something can act where it is not, has lost its application to the case of electric and magnetic actions. Further, the identity of the form of energy in the case of two powerful agents in nature has been conclusively established; light and electrical radiation are essentially the same, different manifestations of the same processes. The old elastic solid theory of optics is thus resolved into an electromagnetic theory. The velocity of propagation of light is the same as that of electro-magnetic waves, and therefore by the laws of optics the scope of optics is enormously widened; to the ultra violet, visible and infra red rays with their wave lengths which can be reckoned only in thousandths of a millimetre, are to be added waves many metres in length; the spectrum is infinitely extended, even if the rods and cones of our eyes do not respond to the new vibrations.

But in another direction we owe much to Hertz's investigations; we are, it appears to me, brought much nearer by them to a solution of the burning question, "What is electricity?" Hertz shows that there is no real electricity which can be regarded as a fluid as in the older theories; what we wished to explain by assuming it are conditions or states of a medium which, although hypothetical, manifests itself by its effects, "the ether, which permeates all matter." Lead to this hypothesis, the phenomena of magnetism, electricity, and light apparently tend at last a single explanation in the vibrations of the ether. Whenever such an edifice is completed, it shall be considerably nearer the possibility of finding a single explanation for the whole of nature. These are the results of the most recent discoveries, in which Hertz has played a most conspicuous part.

A glance over the list of his contributions to science, we ask in astonishment, "Is it possible that one man in the space of thirteen years could furnish such a wealth of new avenues of research?" In the intense suffering of Hertz and his premature decease awakes our deepest sorrow, at the thought of what this mind might have explained makes us rail against the latter fate that took from us; we may still say his was a short but happy and richly rewarded life. The fame of our Hertz is secure and will shine out during centuries of increasing intellectual development, whatever great deeds they may hide in their bosom; the influence of his discoveries will make itself felt as long as electro-magnetic waves continue to heat and illumine the earth.

AMERICAN NOTES.

[FROM OUR OWN CORRESPONDENT.]

NEW YORK, *July 7, 1894.*

Long Distance Electric Roads.—Every now and then we hear of a new scheme for a long distance electric railway, the latest project being for one between Washington and New York, whose promoters have applied for incorporation. None of these ambitious schemes have thus far gone beyond the promotion stage, unless we except the feeble attempts made by the Chicago, St. Louis line, whose prospectus dwelt in such glowing terms on the profits to be derived from transporting World's Fair visitors. In some cases the scheme for a long distance line conceals another purpose, the real object being to secure franchises on better terms for short lines which are represented as sections of a trunk line which is never built.

Purifying Water and Deodorizing Garbage.—Some of the members of the Tammany City Government seem to be greatly interested in a process for purifying the municipal water supply and deodorizing city garbage by electrical means. In the latter case sea water through which an electric current has been passed is mixed with the regular water supply in homeopathic doses. We cannot learn how the process is to be applied to deodorize a garbage island that has become a pestilent nuisance, but this use has been proposed. As residents in the vicinity have applied for an injunction against further dumping there, though in the face of the promise of wonders when the electrical apparatus gets started, we fear that this latest political contribution to electrical science may not have an opportunity to demonstrate its merits in this respect.

Electro Medical Science.—An employé of the Edison lamp works of Harrison, N.J., a few days ago was rendered unconscious by a shock from an electric current, in which state he remained for several days, notwithstanding the efforts of his physician. Finally, becoming convinced that the patient did not recover on account of being "full of electricity," the doctor, applying his electrical knowledge, connected one end of an insulated wire to a water pipe and the other end to a damp sponge, which was rubbed over the body of the injured man. After the first application an improvement was noticed, we learn, and in a short time the patient recovered consciousness and is now convalescent. All of which is hailed by the newspapers as a new curative principle for the treatment of electric shocks.

CORRESPONDENCE.

ENGINE REPAIRS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR,—I am glad to find from Mr. A. Lazenby's letter that the difficulties with closed type engines referred to by me in "Electric Motive Power" are now lessened in the improved types of the Willans engine, and I note that in condensing engines the temperature of the lubricant in the crank chamber does not often exceed 150° F.—Yours, &c.,

Suffolk House, Cannon street, E.C., July 16, 1894. ARTHUR T. SNELL.

LIGHTNING AND WOOD CASING.

TO THE EDITOR OF THE ELECTRICIAN.

SIR,—With reference to your remarks on page 157 regarding the phenomenon of sparking resulting from Hertzian waves impinging upon separated mains leads terminating in two flexible conductors, I should like to point out that danger is also incurred where insulated conductors of opposite poles are placed in contact with each other at the points of crossing in wood casing. In some wiring I have inspected, the first fuse protecting these points was either the main, or was of such large diameter as to render it doubtful if it would act at the comparatively small current that would result from an arc so formed. If the fuse did not blow, and the arc was maintained, the wood casing in the immediate neighbourhood of the latter would probably become ignited.

If this occurred during the night, or at any time with no one at hand to switch off, or if no main switch were provided, it might be difficult to extinguish the fire or limit the damage.

As far as my experience goes, this faulty method of wiring appears to be on the increase, and it would be a desirable for the offices to insist on the separation of conductors until protected by a small fuse.—Yours, &c., CHAS. A. HAWKINS.

July 6, 1894.

LARNE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR,—Your "Note" with reference to Larne in *The Electrician* of the 13th inst. is inaccurate, as there has been no new penalty clause added to our agreement. At the meeting you refer to, the engrossed copy of the agreement was before the Board for signature, but a Commissioner objected to its being completed on the ground that the penalty clause of the draft copy had been omitted in the fair copy, and it was then decided to consult the Board's solicitor, by whom the agreement had been prepared. The solicitor attended a special meeting on the 7th inst., and was able to show the doubting Commissioner that his suspicions were groundless, and that there was no necessity to make any alterations or additions to the agreement. It was then signed by the Chairman and the Commissioners. The discussion over this lighting agreement has been vigorously carried on since last October, and, apparently, there are some members of the Board who do not think the matter has received adequate attention even now. The arc lights referred to are of 1,200 c.p. each, and not of 1,700 c.p. as printed.—Yours, &c., ARCHER TURNER,

Electric Light Station, Larne. Manager and Engineer.

3456-3457

DEFENDANT'S EXHIBIT J-4

adapted to remove any doubt as to the identity of light, radiant heat, and electromagnetic wave-motion. I believe that from now on we shall have greater confidence in making use of the advantages which this identity enables us to derive both in the study of optics and of electricity.

Explanation of the Figures.—In order to facilitate the repetition and extension of these experiments, I append in the accompanying Figs. 35, 36_a, and 36_b, illustrations of the apparatus which I used, although these were constructed simply for the purpose of experimenting at the time and without any regard to durability. Fig. 35 shows in plan and elevation (section) the producing mirror. It will be seen that the framework of it consists of two horizontal frames (*a*, *a*) of parabolic form, and four vertical supports (*b*, *b*) which are screwed to each of the frames so as to support and connect them. The sheet metal reflector is clamped between the frames and the supports, and fastened to both by numerous screws. The supports project above and below beyond the sheet metal so that they can be used as handles in handling the mirror.

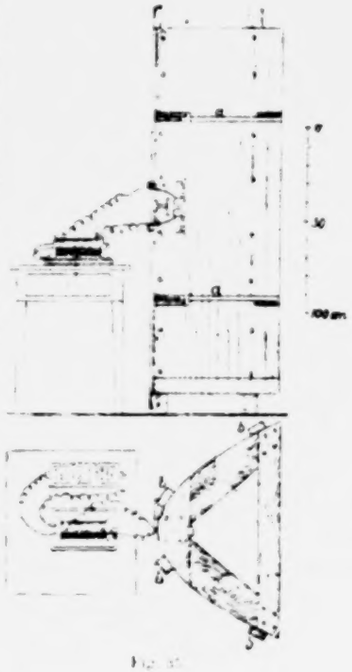

Fig. 35.

Fig. 36_a represents the primary conductor on a somewhat larger scale. The two metal parts slide with friction in two sleeves of strong paper which are held together by indiarubber bands. The sleeves themselves are fastened by four rods of sealing-wax to a board which again is tied by indiarubber bands to a strip of wood forming part of the frame which can be seen in Fig. 35. The two leading

wires covered with gutta-percha terminate in two poles [illegible] in the knobs of the primary conductor. This arrangement allows of all necessary motion and adjustment of the various parts of the conductor. It can be taken to pieces and put together again in a few minutes, and this is essential in order that the knobs may be frequently repolished. Just at the points where the leading wires pass through the mirror they

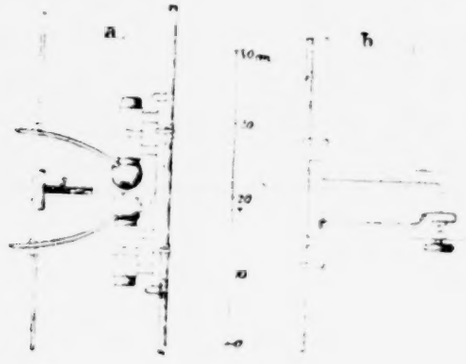

Fig. 36.

are surrounded during the discharge by a bluish light. The smooth wooden screen s is introduced for the purpose of shielding the spark-gap from this light, which otherwise would interfere seriously with the production of the oscillations. Lastly, Fig. 36_b represents the secondary spark-gap. Both parts of the secondary conductor are again attached by sealing-wax rods and indiarubber bands to a slip forming part of the wooden framework. From the inner ends of these parts the leading wires, surrounded by glass tubes, can be seen proceeding through the mirror and bending towards one another. The upper wire carries at its pole a small brass knob. To the lower wire is soldered a piece of watch-spring which carries the second pole, consisting of a fine copper point. The point is intentionally chosen of softer metal than the knob; unless this precaution is taken the point easily penetrates into the knob, and the minute sparks disappear from sight in the small hole thus produced. The figure shows how the point is adjusted by a screw which presses against the spring that is insulated from it by a glass plate. The spring is bent in a particular way in order to secure

The Telefunken or Quenched Spark Discharger. By J. A. Fleming, F.R.S.

In my lecture last Friday evening at the Royal Institution time did not permit me to do more than give a brief description and show one experiment with the multiple small-gap flat plate discharger which has been devised by the experts of the Gesellschaft für Drahtlose Telegraphie for giving practical effect to Prof. M. Wien's method of excitation by shock in spark telegraphy. The methods now in use by that company were being described by Count Arco in a lecture at Cologne at the same hour as my lecture in London, under the title "Das Neue Telefunken System." Although Count Arco had kindly forwarded to me an advance copy of his lecture, I refrained at his request from more than a general statement of the nature of the discharger pending the publication of his lecture in the "Elektrotechnische Zeitschrift."

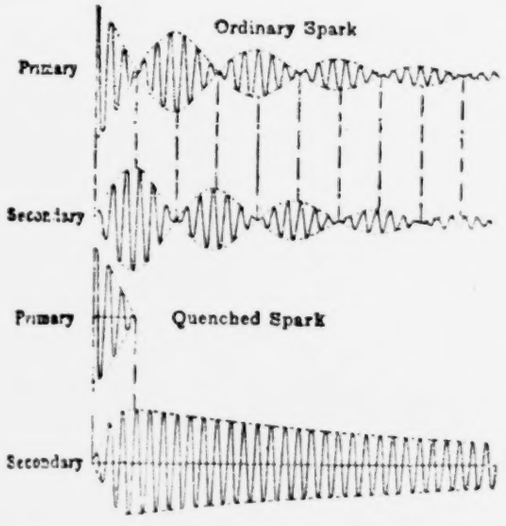

FIG. 1.—Oscillations in inductively-coupled circuits.

As there seems to be an impression that the Telefunken discharger and that of von Lepel are identical, it may be well if I describe here, briefly, experiments which I had not time to shown on Friday evening, and which seem to me to prove that the operative principles involved in the two appliances are different. I explained in the lecture that when isochronous primary and secondary oscillation circuits are connected inductively or directly, as long as the spark endures in the primary circuit so long will those reactions take place which result in the production of a complex oscillation in both circuits resolvable into oscillations of two frequencies. I illustrated this by an experiment with two

equal pendulums hung side by side on a loose string, and showed by means of my cymometer that in the similar electrical case of two equal coupled circuits oscillations of two frequencies were present. If time had permitted, it could have been also shown by the cymometer that these two oscillations were present in the primary as well as in the secondary oscillation circuit when using the ordinary spark-gap in the primary. The Telefunken discharger is based [fol. 3467] on the known fact that the damping of very short sparks is extremely large, and that if we can "quench" or stop the primary oscillations after one or two swings the secondary circuit then continues to oscillate freely with a single period, as shown in Fig. 1.

The discharger I used consisted of 12 round flanged plates of copper, 5 in. in diameter, the surfaces being turned true and having a groove in them (see Fig. 2). A mica ring is interposed between each pair of copper plates of such size that the mica half covers each groove. This groove is important, for without it the discharge spark tends to take place always at the edge of the mica. The mica is of such thickness as to make an air space of not greater than 0.01 in. between the flat copper surfaces. In this discharger we have then, say, 11 air gaps, each about 0.01 in. wide and of circular section. When this discharger replaces the ordinary spark-gap in the primary circuit it damps out instantly the primary spark, and hence excites the free oscillations in the secondary circuit by shock. If, then, we place the cymometer alongside of the secondary circuit we find in it oscillations of only one frequency and not two. Also, if we place it alongside the primary circuit, we cannot detect in that circuit any oscillations, because they are so rapidly damped out that they have too small a mean-square value to affect the cymometer or cause the Neon tube to glow perceptibly.

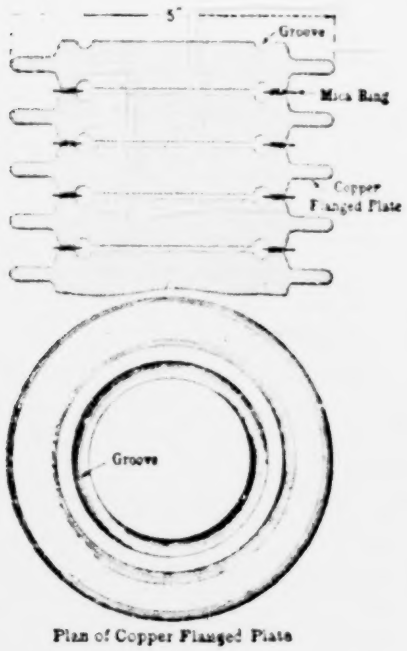

FIG. 2. Plan and section showing portion of disc cover.

In consequence of this rapid damping it is possible to employ an alternator having a frequency of 1,000 to 2,000 to create a corresponding number of primary discharge sparks per second, without producing any true arc discharge. The rapid cooling of the discharge surfaces entirely prevents it.

The discs for this purpose are made of copper or silvered copper plates, and in the case of large discharges the discs are made hollow and water-cooled.

The rapid succession of highly-damped primary sparks creates then an equally rapid succession of very feebly damped trains of oscillations in the secondary circuit having a very large mean-square value, and therefore possessing many of the properties of undamped oscillations generated without any true-arc effect. The operation of this discharger seems to me therefore essentially different from one in which an oscillatory arc is created between metal [fol. 3468] surfaces by the employment of a continuous or direct current, neither is its operation dependent on the presence of an atmosphere of hydro-carbon vapour. On the contrary, it may be described as having most perfect arc-quenching properties possible.

The Telefunken discharger could not, therefore, be placed in the circuit of the antenna as is the generator shown in the diagram of circuits in the article describing the von Lepel system in THE ELECTRICIAN of May 14th, whereas that later mode of connection is quite consistent with a performance of a discharger which is essentially an arc method and not a spark method.

Three other properties of the Telefunken discharger deserve notice. It is almost noiseless, and, being entirely enclosed, could be used in an inflamable atmosphere. It seems, therefore, likely to be of use in balloons or airships where an open or naked spark could not be employed. Finally, as the whole of the energy transferred to the secondary circuit expends itself in the production of radiation of one single wave-length it must be more economical than methods which generate waves of two wave-lengths, but capture at the receiver radiation conveyed by only one of these wave-lengths.

DEFENDANT'S EXHIBIT C-5

The Electrician, London, November 10, 1911

The Telefunken System of Wireless Telegraphy

Commercial wireless telegraphy in Germany owed its early progress to two groups of workers—namely, Prof. Braun, of Strassburg, on the one hand, whose wireless telegraph company became amalgamated with Messrs. Siemens & Halske, and, on the other hand, Prof. Slaby and Count von Arco, who were associated with the Allgemeine Elektricitäts-Gesellschaft (more generally known by the abbreviation "A.E.G."). Both these companies carried on a business in wireless telegraphy, but in 1903 the advantages of consolidation became evident, and the two companies combined to form the Gesellschaft für drahtlose Telegraphie m.b.H., Berlin. Thenceforth this Company supplied stations based on the combination of the Braun-Siemens and Slaby-Arco systems, and the resulting system became familiar under the shorter name "Telefunken." As was only to be expected, this amalgamation of interests produced a rapid development.

In what follows we are able, through the courtesy of the Telefunken Company (to use an abbreviated title) to give a complete account of the "singing spark" system and the apparatus with which the Telefunken stations are equipped.

Up to the year 1907 the slow spark was used by the Company (that is, about 20 sparks per second), but in that year the spark frequency was raised, with the result that the range of existing stations became approximately doubled. Since that time, however, a further great change has been introduced by using "singing quenched sparks."

It is well known that when two oscillating circuits are coupled together, the energy sways backwards and for[fol. 3469]wards from one to the other, and that each circuit emits waves of two frequencies; and this leads to serious inefficiency in practice with the usual spark, because only one of the two frequencies can be utilised. In 1906 Prof. Max Wien contributed an important article to the "Physikalische Zeitschrift," in which he showed that if the oscillations in the primary circuit were stopped as soon as the secondary circuit was oscillating, the latter would continue to oscillate at its natural period, and would therefore emit waves of only one frequency. A much higher efficiency

is, therefore, to be expected with the "quenched spark" than with the ordinary spark.

What takes place is shown graphically in Fig. 1. The two top curves show a train of oscillations in the primary and secondary circuits in the case of the ordinary spark, and it is seen that a maximum amplitude in one corresponds with a minimum amplitude in the other. Instead of the secondary giving a regular train of oscillations with decreasing amplitude it oscillates with "beats," in the same way as beats are heard when two notes of nearly similar pitch are sounded together. In the case of such coupled circuits, by means of a wave meter the two waves can be detected easily; and as a tuned station can only respond to the frequency to which it is turned, only one of these waves can be used, and thus half the energy is wasted. It is true that a single wave is obtained in the two extreme cases of very tight and very loose coupling, but neither of these afford a practical solution.

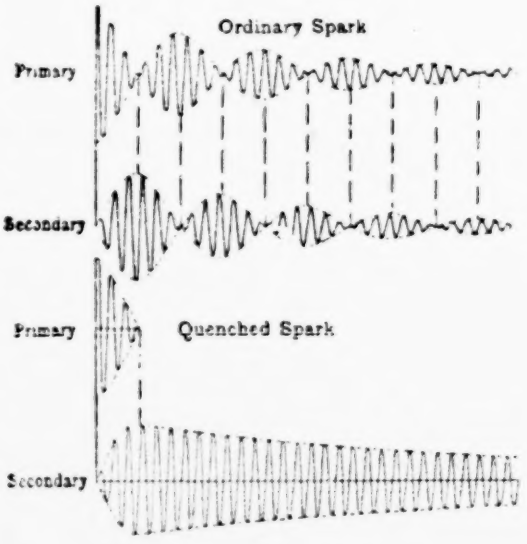

Fig. 1.—Diagram of oscillations in coupled circuits. (a) Ordinary spark, (b) quenched spark.

In the quenched spark system, on the other hand, the spark is quenched as soon as the energy in the primary circuit is a minimum and that in the secondary a maximum. Thus, after quenching, the primary no longer oscillates, and the secondary oscillates with its natural period; so that, under suitable conditions, a feebly damped train is obtained, as indicated in the lower part of Fig. 1.

In all probability many people worked unwittingly with the quenched spark before the appearance of Prof. Wien's Paper, for the conditions for quenching are easily obtained. With ordinary circular electrodes placed close together, or even with quite thin plates placed edge to edge so as to

form a small gap, quenched sparks are obtained and will continue so long as the heat is conveyed away rapidly [fol. 3470] enough. As soon, however, as the electrodes become hot the spark becomes an arc (that is, the metal is volatilised and takes part in the conduction) and quenching no longer occurs. Also a single wave is not obtained unless the spark gap is quite small, as is shown by the curves in Fig. 2 (due to Prof. Wien). If the gap is not very small two waves are obtained, both differing from that of resonance as already mentioned.

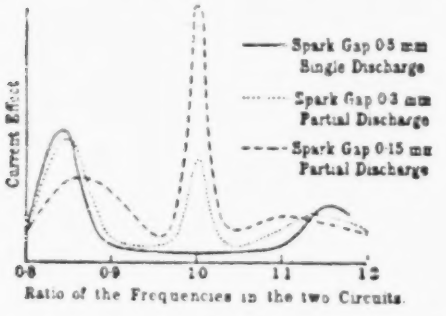

Fig. 2.—Curves showing the importance of small gaps in producing a single wave by quenched spark.

In the Telefunken system the exciting circuit containing the quenched spark gaps is coupled either directly or inductively to the syntonised antenna system. The coupling is made sufficiently close that the transfer of energy from the exciting circuit to the antenna takes place quickly, but, on the other hand, the coupling is so loose that quenching begins after the first "beat" oscillation. It is found that the most suitable degree of coupling is 20 per cent., whence it follows that the number of half waves in the primary before quenching occurs (being 1/λ) is five. To give the best result it is necessary that the reaction of the secondary circuit should assist the quench-

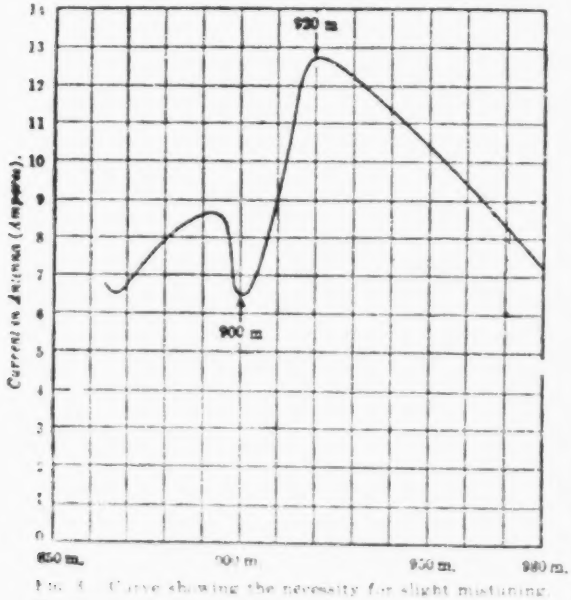

Fig. 3.—Curve showing the necessity for slight mistuning. Primary wave maintained constant at 900 metres. Secondary wave varied.

ing in the primary, and for that reason the two circuits are slightly mistuned—namely, to the extent of about 2 per cent. The closer the coupling the greater must be the mistuning. In practice the coupling is varied until an ammeter in the antenna shows a maximum, and in this way two or three maxima can be found, but the best result is obtained with about 20 per cent coupling.

Fig. 3 is an illustration of the effect of tuning. Here the primary wave was kept constant, and it is seen that the maximum in the antenna was not obtained when the circuits [fol. 3471] were in tune; one occurs on each side of the position of syntony, but the best condition appears in this case when the secondary wave length is 920 metres as compared with 900 for the primary.

In Fig. 4 are given resonance curves of the primary, when the secondary wave length is kept constant, for different couplings and primary wave lengths. It will be noticed that the primary wave is of practically the same length as

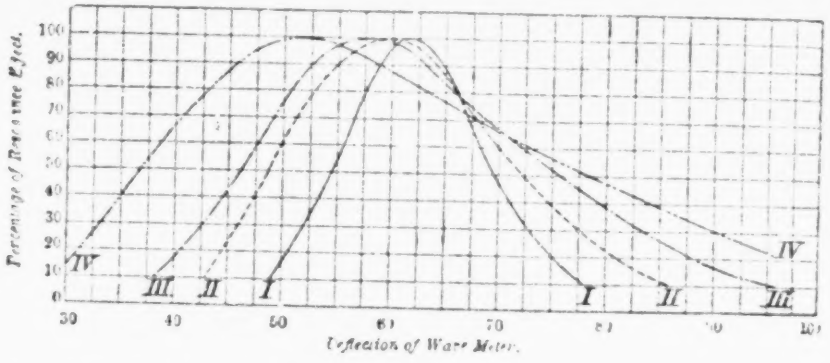

Fig. 4.—Resonance curves with quenched spark for various couplings and secondary wave constant.

	Coupling	Primary Wave Length	Secondary Wave Length		Coupling	Primary Wave Length	Secondary Wave Length
I	0·05%	1340	1340	III	9%	1294	1340
II	7%	1312	1340	IV	18·2%	1230	1340

the secondary wave for a very loose coupling, but there is an increasing difference as the coupling is made closer. The curves in this figure are not symmetrical because the wave meter readings were merely deflections, not wave lengths.

Since each spark gives rise to a definite series of oscillations if the quenching is precise, it follows that this system permits the use of a very regular series of sparks. By using

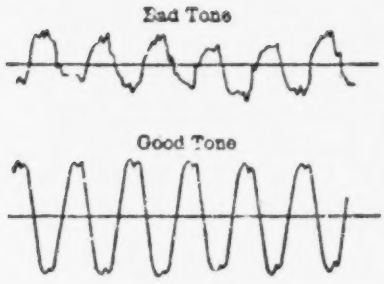

FIG. 5.—Oscillograph records of good and bad tones.

a rapid series a musical note is obtained in the telephone corresponding to the frequency of the oscillation groups or sparks, and this note is very easy to hear. Consequently the quenched spark system has three main advantages:

1. The transmitting apparatus and antennæ are small.

1. The transmitting apparatus and antennæ are small.

2. Large ranges.

3. High speed.

For producing the discharge continuous current might be used, but this has the disadvantage that it tends to give arcs, and high tensions are not produced easily. Further, continuous current would lead to complications in the receiver, and for this reason alternating currents of com- [fol. 3472] mercial frequencies were also discarded. Recourse was, therefore, had to an alternator giving a frequency of 500 (*i.e.*, 1,000 sparks per second). If there is merely one spark per half period a very good tone is obtained. This point is illustrated by the oscillograph records in Fig. 5. In the upper curve three partial sparks take place per half period and the tone is bad, whereas in the lower curve only one discharge per half period takes place. It is necessary to have the alternator circuit nearly resonant. It is not made quite resonant because the spark resistance introduces a variation. Thus the circuit is tuned for, say, 1,300 revs. per min., but the alternator is run at 1,500 revs. per min.

The speed of the alternators that are used can be varied about 50 per cent., and a pure tone can be obtained for each speed. Thus the tone can be varied continuously through half an octave; in addition, there are regulating devices combined with the machine or transformer, by which the

tone can be adjusted to the lower fifths and to the two lower octaves. These last-mentioned variations, in the case of small stations up to 2 kw., can be effected by depressing keys.

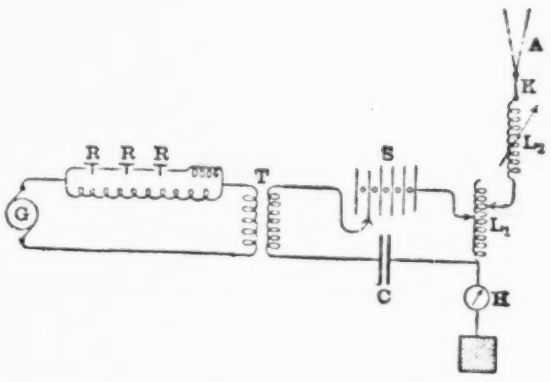

Fig. 6. Diagram of transmitting system.

Before describing the component parts of the Telefunken system it may be convenient to refer to Figs. 6 and 7, which show the connections for transmitting and receiving respectively. The alternating current is brought to a transformer, where it is raised to an appropriate pressure (4,000 to 70,000 volts, depending on the size of the station), the secondary being connected with the spark discharger on the one hand and to a capacity on the other. This circuit is coupled either directly or inductively to the antenna. The capacity is not variable in small stations, but may be half cut out in large stations if desired. The antenna contains a variable inductance, and is earthed through an ammeter.

The damping of the waves radiated is about 0.08 to 0.1 with slowly radiating umbrella and *T* antennæ, if the latter are working with their natural wave length, and only 0.05 to 0.03 if the wave length is increased to three or four times the natural length. The period of the high-frequency circuit is absolutely constant, so that, in contradistinction to arc lamp excitation, the resonance can be completely utilised. Owing to the very slight damping of the antenna, intermediate circuits between the exciter and the antenna have not been introduced. The damping of such a circuit [fol. 3473] would have to be one-tenth that of the antenna to work satisfactorily; that is, not more than 0.01 to 0.005. This is difficult to achieve, and would lead to rather com-

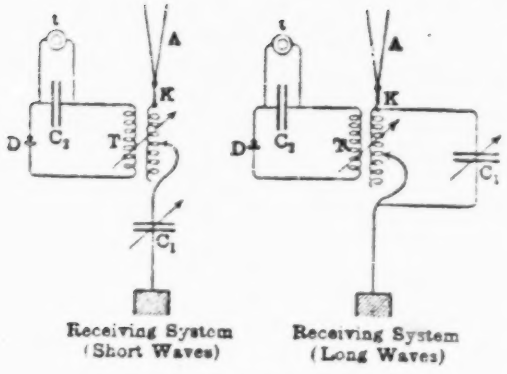

FIG. 7.—Systems Used for Receiving.

plicated arrangements. The only cases in which an intermediate circuit may be necessary are when it is impossible to use a standard form of antenna.

For receiving, the antenna is switched over to a transformer, which couples it inductively with a closed receiving circuit. For short waves the primary of this transformer is in series, with a variable capacity and thence to earth. For long wave lengths, on the other hand, the inductance and capacity are in parallel. The secondary of the transformer is taken to the detector and a small fixed capacity in series. Across the poles of this capacity is the telephone.

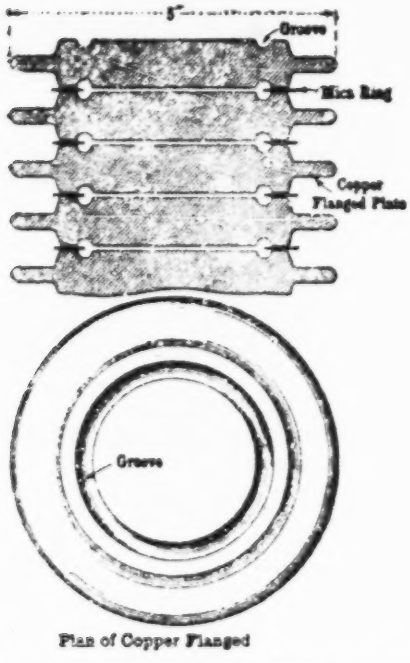

FIG. 8.—Section and Plan of Spark Discharger.

Owing to the oscillations in the primary sending circuit persisting for only a short proportion of the whole time, the primary losses are not so important as usual, and therefore paper condensers are often used instead of Leyden jars, a number being connected in series. Further, brush discharges from the edges of the condensers do not occur nearly so much as in the case of slowly quenched circuits, doubtless because local ionisation is reduced.

Inductances for the smaller stations are made of finely-stranded wire, but for the larger stations copper strip is used in the form of flat spirals. In the case of wound inductances very fine specially enameled copper wire is used to keep down the eddy

(Here follows 1 photolithograph, side to fol. 3474.)

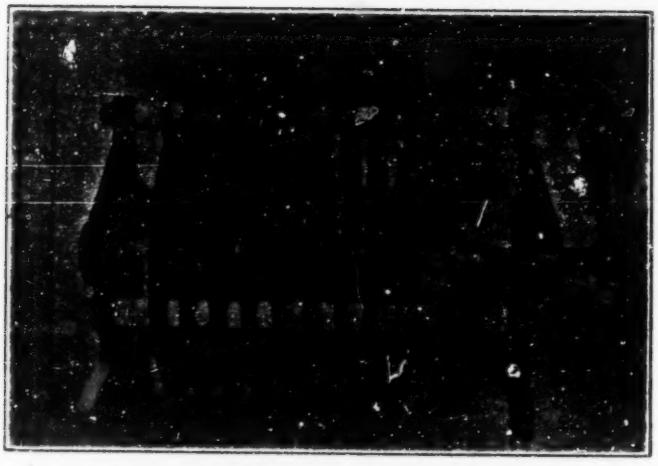

FIGURE 9 —VIEW OF SPARK DISCHARGER.

FIGURE 11 — ARRANGEMENT FOR TESTING DETECTORS

current loss to a minimum, and as the resistance must be very low to correspond with the antenna, and since large currents are used, as many as 10,000 to 20,000 separate insulated wires are sometimes run in parallel. Since all such wires should carry the same current, special windings are employed by which each wire has the same resistance and inductance.

[fol. 3475] *The Spark Discharger.*—A section of the spark discharger as now used by the Telefunken Company is shown in Fig. 8. It consists of circular plates of copper, each faced with a plate of silver, which is ground dead true except that it is slightly recessed at the centre. There is a groove some distance from the centre and the metal plates are separated by mica rings to a distance of 0.2 mm. The spark forms at any point of the flat surface; it is then forced towards the periphery in a radial direction by the electromagnetic field, and is eventually extinguished on its path. A number of these spark-gaps are held in series, as shown in Fig. 9. It will be noticed that between each pair of these discs is a larger disc of thin copper, which is effective in radiating the heat generated by the spark. These radiating discs are carried by three porcelain tubes, and these tubes are so placed that the inner discs can rest upon the two lower tubes. Thus it is a very easy matter to take a disc out or to replace it. The spark gaps are pressed together in the frame by means of a screw, and the insulation provided at each end consists of short glass cylinders. The whole arrangement, as is shown by the illustration, is very compact and serviceable. Short-circuiting plugs, which are simply "U"-shaped pieces of metal, are provided, in order to short-circuit as many gaps as may not be required. Two of these are seen in position in the illustration. By connecting a suitable number of gaps in series it is possible to keep the energy per gap from exceeding a certain value, and thus to prevent overloading. Since the energy transmitted varies as the square of the number of spark gaps the regulation by short-circuiting covers a wide range. Thus if there are 10 gaps and 9 are cut out, the maximum energy is reduced to 1 per cent. In the case of small dischargers

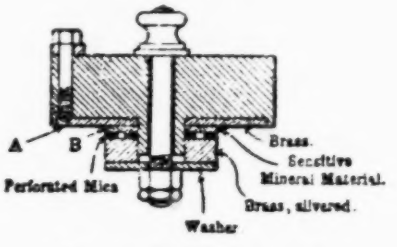

FIG. 10.—Section of detector.

point of connection of the circuit to the discharger is made variable and short-circuiting clips are not used. The pressure per gap is 1,200 volts.

Water cooling is not adopted, but dischargers are sometimes used with air ducts, and the radiating discs are also varied in size according to requirements.

The Detector.—Since the waves to be received are intermittent but rapid, so called integrating or contact detectors are chiefly employed for receiving, the contact being between a mineral and graphite or a metal. A high-frequency safety device is employed to protect the detector in case of sudden overloads.

The construction adopted will be understood by reference to Fig. 10, which, however, is not to scale, though roughly full size. From this it will be seen that the essential parts are a washer of brass, A, as one terminal, against which is pressed a sensitive mineral washer. The desired pressure is obtained by screwing down a second brass washer B (which may be regarded as the other terminal), through [fol. 3476] a mica washer which is perforated with a number of holes. The surface of B next the mica is corrugated and silvered, and it will be realised that the pressure necessary to secure contact between B and the mineral must be considerable. In fact, to anyone having the idea that the detector is a delicate piece of apparatus, the rapidity and ease with which these detectors are assembled and adjusted in the laboratories of the Telefunken Co. comes as a surprise.

The detectors are adjusted by mounting them inverted in a block, as seen in Fig. 11, and adjusting the nut until comparison with a standard detector is satisfactory. A complete detector is seen to the left of this illustration. In the laboratory, detectors are not only adjusted for sensitiveness, but are also adjusted to an internal resistance best suited to the coupling conditions of the receiver; further, they are tested for about 100 times the working intensity and are submitted to a vibration test.

The detector is used without an auxiliary battery and rectifies the alternating impulses into a pulsating continuous current. With a telephone as a receiver there is a distinct advantage in having these impulses of a regular frequency, because the diaphragm will then respond most readily and give a musical note, whereas irregular disturbances, even of considerably greater energy, will produce no appreciable

effect. In fact the higher the tone the more sensitive the telephone, and the less trouble is there from atmospheric disturbances. A galvanometer, on the other hand, would give the mean detector current, and its deflection would increase with the energy irrespective of the regularity of the impulses. The musical tone is very easily distinguished, and if pure it can be heard quite clearly even when very weak. A range of tones of about 200 to 2,000 vibrations per second is obtainable, and various tuned transmitters can be easily distinguished from each other. The musical tone is thus important, the more so in that it is not readily confused with atmospherics.

Receiving set.—The receiving set is very compact, and is shown well in Fig. 12. At the back is seen the antenna switch, and when this is thrown over for receiving, the antenna is connected to the primary coil of the coupling transformer. On the other hand, when this switch is open for sending, the circuit is automatically broken on each side of the detector and also the telephone circuit. One of these primary coils is shown in position, and two more are seen along side the apparatus. The inductance in the antenna can be varied in three steps for each coil by means of a plug which can be inserted into any one of the three holes on the face of the coil. Since two or more coils are provided, and these can be easily interchanged, a large range of inductance is available. The primary is connected in series or in parallel with the capacity and thence to earth. The capacity is of the usual air type with semicircular plates and is continuously variable by turning the knob seen in the illustration.

(Here follows photolithograph, side folio 3477)

FIGURE 12 RECEIVING SET

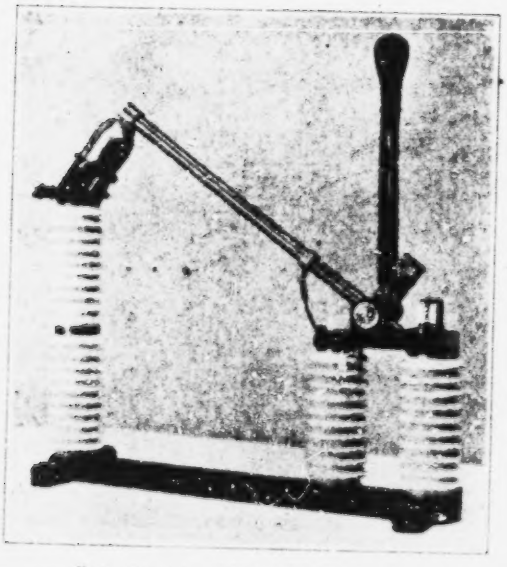

FIGURE 13 ANTENNA SWITCH

The secondary of the transformer can be moved outwards, as it is hinged, and when it is moved outwards to the horizontal position it can also be turned round upon a [fol. 3478] horizontal axis. Consequently, the coupling can be varied between extreme limits. The inductance in the secondary can also be varied in six steps by changing the position of the plug, which is seen at the end of a flexible connection. A small switch will be noticed below the coupling transformer. The object of this is to connect the inductance and capacity in series for receiving short waves and in parallel for receiving long waves. The detector is seen below the switch, and terminals are provided for connecting up the telephone or call apparatus as desired. A continuous wave range of 250 to 2,500 metres is covered by turning the condenser and by a single interchange of coupling coils.

Since the energy from the antenna is transferred from the coupling coil of the antenna to an aperiodic circuit containing the detector, the receiving antenna alone requires syntonising, and this is effected simply by turning the condenser. Owing to the smallness of the damping of the quenched spark waves, very exact tuning is obtainable.

When stations have highly damped antennæ of large capacity, this simple arrangement cannot be adopted because the enormous atmospheric disturbances met with in the case of large antenna are carried with almost their full force to the detector, causing serious reduction in its sensitiveness and often damaging it. This difficulty is obviated by the use of a very weakly damped intermediate circuit, which is coupled very loosely with the antenna, and not too closely with the detector circuit.

For stations above a certain size a separate antenna switch is used, as shown in Fig. 13. With the switch down, as seen in this illustration, the antenna is connected for receiving, and when it is pulled over to the right, connection is made for transmitting.

(To be continued.)

DEFENDANT'S EXHIBIT D-5

Wireless Telegraphy, by Zenneck, 1915

• • • • • • •

Whenever the coupling is fairly close, K' is considerably greater than $\left(\frac{d_1-d_2}{2\pi}\right)^2$, so that the quantity K' is not much different from the coupling coefficient K. (See note 4, p. 87.)

Under these conditions there are in general[57] two distinct oscillations the so-called "coupling oscillations" (coupling waves") produced *in both the primary and the secondary circuit*, having *two distinct frequencies*, N' and N'', *and two distinct decrements*, d' and d''.

If, as heretofore, we use I_1 and V_1 to indicate current and voltage in the primary circuit, I_2 and V_2 the same in the secondary then I_1 (and V_1) as well as I_2 (and V_2) are the results of two oscillations. Hence we may write:

$$\begin{aligned} I_1 &= I_1' + I_1'' \\ V_1 &= V_1' + V_1'' \end{aligned} \quad \text{for the primary circuit.}$$

$$\begin{aligned} I_2 &= I_2' + I_2'' \\ V_2 &= V_2' + V_2'' \end{aligned} \quad \text{for the secondary circuit.}$$

[fol. 3479] The various oscillations have the following frequencies, wave lengths and decrements.

$$\left.\begin{matrix} I_1' \text{ (and } V_1' \text{)} \\ I_2' \text{ (and } V_2' \text{)} \end{matrix}\right\} N', \lambda' \text{ and } \delta'$$

$$\left.\begin{matrix} I_1'' \text{ (and } V_1'' \text{)} \\ I_2'' \text{ (and } V_2'' \text{)} \end{matrix}\right\} N'', \lambda'' \text{ and } \delta''$$

59. *The Frequency of Coupling Waves.* — *a. Primary Circuit without Spark Gap.* — Let the index I refer to the oscillation having the higher frequency and shorter wave length. Then we have[57]:

. . . . . .

Hence, the greater K', *i.e., the closer the coupling, the more will the frequencies (wave-lengths) of the coupling waves differ from each other and from the original common frequency (wave-length).*

b. Primary Circuit with Spark Gap. — In this case also the relations between the frequencies before and after coupling are of the *form* of equations (1). It is not definitely known, however, though this is of no practical importance, whether the factor K' has the relation to the coefficient of coupling, K, and the decrements given by equation (1) of Art. 58. The quantity which actually determines the extent of the coupling and which may be directly measured by test [Art. 87] is the factor K' for circuits with spark gap also.

K' is called the "degree of coupling." Its value is frequently expressed in percentage, thus: "3 per cent. coupling" means $K'=0.03$. The relation between N^I, N^{II} and N, as well as z^I, z^{II} and z is given in Table X for different values of K'.

c. The *resultant oscillation* produced from the two coupling oscillations of different frequency is of the form shown diagrammatically in Fig. 130, and shown in Fig. 124 as obtained with an oscillograph (H. Diesselhorst [88]) and in Fig. 125 as photographed from the spark discharges (H. Rau [89]). The resultant oscillation may be conceived as having the frequency N and an amplitude which periodically increases and decreases, similarly to the *beats* or *pulsations* of a tone which are observed in acoustics.

85 369 373

(Here follows photolithograph, side folio 3480)

FIGURE 124

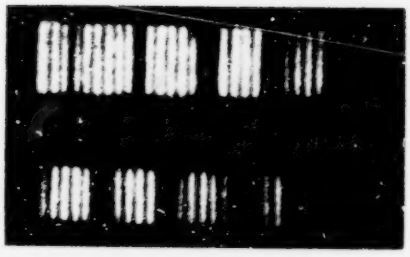

FIGURE 125

The greater the difference between the frequencies of the two oscillations, *i.e.*, the closer the coupling, the greater is the number of pulsations obtained per second. This number, S, which is the number of times per second that the amplitude passes through zero, is given by

$$S = N^I - N^{II} = \text{approx. } NK'$$

Hence the duration of one beat or pulsation is approximately $= \frac{1}{NK'}$ seconds $= \frac{1}{K'}$ periods.

d. The *energy relations*, as is evident from Fig. 130, are as follows: Originally the entire energy resides in the pri- [fol. 3481] mary circuit. After half of one pulsation the amplitude of the oscillation in the primary circuit is zero, while that in the secondary is a maximum and the entire energy has been transferred to the secondary circuit. After another half pulsation all the energy is again back in the primary and the secondary is at zero, etc., etc. In short, the energy continues to swing back and forth between the primary and secondary circuits.

60. *The Decrements of the Coupling Waves.—a. Primary Circuits without Spark Gap* (P. Drude[89]).—The relations of the decrements before and after coupling are expressed by:

$$\left.\begin{aligned} d^I &= \frac{d_1+d_2}{2}\frac{N^I}{N} = \frac{d_1+d_2}{2}\frac{\lambda}{\lambda^I} \\ d^{II} &= \frac{d_1+d_2}{2}\frac{N^{II}}{N} = \frac{d_1+d_2}{2}\frac{\lambda}{\lambda^{II}} \end{aligned}\right\} \quad \frac{d^I}{d^{II}} = \frac{N^I}{N^{II}} = \frac{\lambda^{II}}{\lambda^I}$$

So that while for low degrees of coupling the decrements of the two oscillations are approximately equal to the average value of the decrement before coupling, *as the coupling becomes closer, the decrement of the oscillation having the shorter wave-length increases and that of the oscillation having the longer wave becomes less than the average value mentioned above.*

Theoretically the closest possible coupling exists when $K'=1$; in practice about the highest value obtainable is approximately $K'=0.6$. For this latter value, we have:

$$\begin{aligned} N^I &= 1.6\,N & d^I &= 0.8\,(d_1+d_2) \\ N^{II} &= 0.8\,N & d^{II} &= 0.4\,(d_1+d_2) \end{aligned}$$

Hence in practice the frequency and decrement of the oscillation of shorter wave-length will at most be twice what they are for that of the longer wave.

b. Primary Circuit with Spark Gap. (C. Fischer[30]). —In this case the relations of *a* do not hold.

1. The decrements of both oscillations, particularly if the coupling is loose, are greater than would follow from *a*.

2. It is by no means always the oscillation of shorter wave-length which is the most highly damped. *On the contrary, this usually is more slightly damped than the oscillation of greater wave-length.*

The conditions obtained by coupling a condenser circuit containing a spark gap with another having no gap, were observed by C. Fischer, whose results are shown in Figs. 126 and 127. Fig. 126 refers to the case of primary and secondary capacities being practically equal[1] while in Fig. 127[2] the capacity in the primary circuit is much greater than that in the secondary.

61. *Amplitude and Phase of the Oscillations*[31].—*a. Amplitude.* The current amplitudes of the individual oscillations have the same relation, approximately, as their frequencies, *i. e.*,

$$J^{(1)}_1 : J^{(2)}_2 = N^1 : N^{11}$$
$$J^{(2)}_1 : J^{(1)}_2 = N^{11} : N^1$$

[tol. 3482] *The current amplitude of the oscillation having the shorter wave-length is therefore greater than that of the longer wave oscillation.*

Assume a given known value for the initial potential V_{10} of the primary circuit, then we have the following expres-

[1] $C_1 : C_2 = 0.85 : 1.0$ MF. $L_1 : L_2 =$ approx. 22,000 C. G. S. Length of gap .36 mm.

[2] $C_1 : C_2 = 0.29 : 1.0$ MF. $L_2 = 6230$ C.G.S. Gap 6.8 mm. approx. $C_1 : C_2 = 0.45 : 1.0$ MF. $L_2 = 73{,}000$ C.G.S.

[3] If the current in one of the circuits is not quasi-stationary, the current amplitude is to be understood as the value at the current anti-node.

sions for the current and voltage amplitudes in a secondary circuit having quasi-stationary current:[4]

. . . . . .

b. Phase. If we consider as positive the direction of the oscillating current I (one) in both circuits, the vector dia-

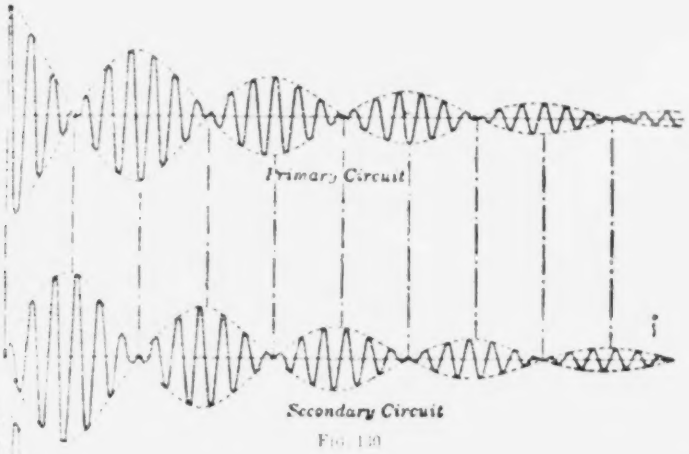

Fig. 130

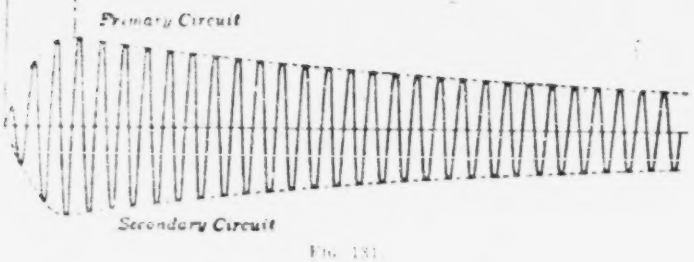

Fig. 131

gram will have the form of Fig. 128. The angles of phase displacement φ' and φ'' are given approximately by

. . . . . .

[4] If neither primary nor secondary circuit has quasi-stationary current, these relations, to the extent of their involving the voltage, hold only approximately; those independent of V_{∞} are correct if the value of the current anti node is taken as the current amplitude.

In all practical cases, as long as the coupling is fairly close[1] these angles are very small. We may therefore state roughly: *of the oscillations in the primary and secondary circuits having the same frequency,*

. . . . . .

the one pair (I_1', and I_2') are almost in phase, while the other pair (I_1'', and I_2''[2]) are approximately 180° *apart.*

c. The maximum amplitude of the resultant oscillation in the secondary circuit depends not only upon the amplitude of the two component oscillations, but also upon their phase and damping.

4. Quenching Action in Coupled Circuits (M. Wien[92])

62. *Form of the Oscillations.*—In Art. 59 it was stated that under the conditions therein specified the oscillations in the primary and secondary circuits would be of the nature illustrated in Fig. 130.[3] In the primary circuit, after lapse of half a pulsation, the amplitude of the oscillation is zero or nearly zero. It then increases again, this being due to the fact that the secondary, whose amplitude is at its maximum at that moment, induces an EMF in the primary, producing a difference of potential between the electrodes of the spark gap.

The conditions may be such, however, that the spark gap, during the time in which the amplitude in the primary circuit is very small, becomes so deionized, that the EMF induced by the secondary is no longer sufficient to start or "ignite" a spark discharge across the gap. As a result the spark gap remains quenched—whence the terms "quenching action" or "quenched gap." The oscillations in the primary then discontinue entirely and the secondary circuit continues to oscillate with its natural damping and at its graph Fig. 132 [H. Rau[93]].)

[1] Assume $d_1 = 0.08$ and $d_2 = 0.2$; then K' need only be large as compared to 0.02. If the secondary circuit is less damped the conditions become still more favorable.

[2] i is used in Fig. 128 instead of the capital I.

[3] Assumption: $d' = d'' = 0.08$; $K' = 0.16$.

natural frequency just as if the primary circuit did not exist. Compare the diagrammatic Fig. 131 and the spark photo-

[4] Assumption: $d_1 = 0.03$; otherwise just as for Fig. 130.

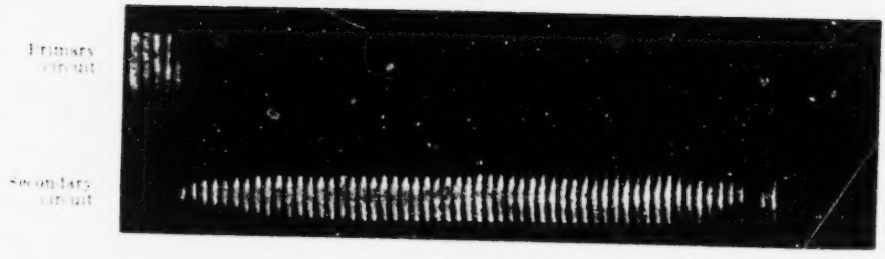

FIGURE 132.

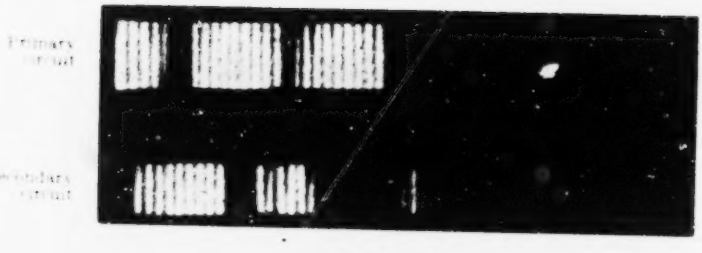

FIGURE 133.

[fol. 3484] 63. *Various Types of Quenched Gaps.* — *a. Very short metallic spark gaps* (M. Wien) are of special importance in practice.

Not only the *material* of which the electrodes are made but also the *gas* in the gap between them is of importance. Particularly good quenching action is obtained with silver and copper, aluminium is less satisfactory and zinc, tin and magnesium do not give good quenching (M. Wien[95]); platinum-iridium alloy is also quite effective with short gap lengths (H. Boas[93]). The quenching action is increased if the sparks are passed through *hydrogen* instead of air (J. *Espinosa de los Monteros*[94]).[9]

b. For laboratory purposes the so-called *mercury-arc lamp*, i.e., an exhausted glass tube with mercury electrodes (R. Rendahl[95]) is very well adapted. Apparently the only essential element in the form of this lamp is the provision of a sufficiently large space over the electrodes for cooling and condensing the mercury vapor. Moreover the tube must have a high vacuum and pure mercury must be used.

c. With primary circuits having long gaps, which in themselves would have no quenching action, it is possible to [fol. 3485] secure quenching by greatly increasing the damping of the primary circuit through an inserted resistance, or better still, by inserting a glass tube filled with gas at very low pressure (*e.g.*, 3 mm. mercury) and having metallic electrodes — a so-called "quenching tube" (M. Wien[95]).

64. *Requirements for Good Quenching.* — *a. Time-lapse of One Pulsation.* In view of the fact that the primary circuit consumes less energy the sooner the oscillations in it are quenched,[10] *i.e.*, for the sake of efficiency, it is desirable to make the coupling as close as possible. The closer the coupling, the shorter will be the time-lapse or duration of one pulsation, which is the time during which the primary circuit remains active [59c].

On the other hand, however, the time during which the amplitude in the primary remains very small and, hence, the time during which the spark gap is subjected to deioniza-

[9] In regard to hydrogen quenched spark gaps [see Art. 109c].

[10] For the same decrement; this also affects the efficiency [*b*].

tion becomes shorter as the coupling is made closer. If this time is made too short, "pure" quenching is no longer obtained, *i.e.*, the primary oscillation is not suppressed after one-half a pulsation. Either coupling oscillations result or intermediate conditions between distinct coupling oscillations and pure quenching are obtained; thus the primary oscillations disappear only after one and one half or two and one half pulsations (Fig. 133, H. Rau").

Hence close coupling is desirable for efficiency, while loose[28] coupling is needed for pure quenching. It follows that for every spark gap there must exist a "critical degree of coupling," at which pure quenching is still just obtainable. This is of course always used in order to secure as high efficiency as possible. The higher the critical percentage of coupling, the better will be the quenching action of the given spark gap.

b. Pureness of the Pulsations. It is most favorable for the quenching action if the amplitude of the resultant oscillation in the primary circuit really becomes *zero* after the first half pulsation, that is, if the pulsations are *pure*. The essential condition for this, however, is that both oscillations, after half a pulsation, have the same amplitude but are opposite in phase.

Whether this condition obtains depends upon the accuracy of the tuning between the primary and secondary circuits; the more exact the tuning, the purer will be the pulsations, other things being equal. Moreover, even with perfect tuning, it is evident that the pureness of the pulsations depends upon the initial amplitude of the two oscillations and their *decrements*. In this connection, therefore, the decrement of the primary and secondary circuits becomes of importance. As the decrements of the coupling oscillations also depend on the degree of coupling, the latter affects the quenching action in this way also.

Apparently this effect of the degree of coupling plays a part in connection with the following phenomenon (H. Rieg[29]). If the degree of coupling is gradually increased a *first* critical coupling is reached, beyond which pure quenching is no longer attainable. If, however, we proceed to make [fol. 3486] the coupling much closer, a degree of coupling is reached at which pure quenching is again obtained (*second* critical percentage of coupling). In fact, under certain conditions, a *third* critical coupling may occur. The critical de-

gree of coupling of a quenched gap is therefore by no means always a single definite quantity.

The pureness of the pulsations probably also plays a part in the explanation of the fact that by bringing the primary and secondary circuits slightly out of resonance, a pure quenching can be obtained, after the quenching had been spoiled with primary and secondary entirely in tune (H. Riegger [7]).

c. The magnitude of the EMF induced in the primary by the secondary circuit is also affected by the degree of coupling; in fact, is proportional to the coefficient of coupling, other things being equal. Hence the greater the coefficient, so much greater is the danger that a discharge will pass across the spark gap after half a pulsation.

d. Lastly, the *temperature of the electrodes*, that is, not the average temperature, but the maximum at any point (*local heating*) affects the quenching, as when the temperature becomes very high the gas is highly ionized, thereby greatly reducing the quenching action as well as the discharge voltage. This makes it easier for another spark to jump across the gap after the first half pulsation. Hence, care must be taken that the temperature does not rise too high at any part of the gap electrodes.[96]

65. *Concerning the Nature of the Quenching Action.*—*a.* The general requirement for the best quenching action is identical with the requirement for the quickest possible deionization of the spark gap. The deionization may have several causes, viz.:

1. The *recombining* of the positive and negative ions; when two ions of opposite charge collide, this may result in a neutralization of their charges.

2. *Diffusion* of the ions from the gap space between the electrodes into space without; just as a gas (*e. g.*, illuminating gas), pouring out from some opening will spread out in all directions (diffuse) in the surrounding medium (*e. g.*, air), so the ions diffuse from the space in which they were formed into the surrounding gas.

3. *Absorption* of the ions at the gap electrodes. If an ion comes close to a piece of metal, the latter will have the same

effect upon it as any uncharged conductor has on a charged body, viz., an attractive force. Consequently the ion comes into contact with the metal and gives its charge up to it.

This last kind of deionization is also influenced by the diffusion of the ions. The faster new ions are diffused from the outer space to the surface of the gap electrodes, the quicker will deionization take place, corresponding to a greater coefficient of diffusion.[11]

4. *Deionization by the Electric Field between the Gap Electrodes.*—If an electric field exists between the gap elec- [fol. 3487] trodes, the positive ions are attracted to the negative electrode, the negative ions to the positive electrode, where they give up their charge. In the case in point a field

. . . . . .

[11] The coefficient of diffusion D is defined as follows: If c' is the concentration factor (=change in the number of ions present in 1 cc., along a length of 1 cm.), then the number of ions diffused through a section 1 cm. sq. per sec. is Dc'.

DEFENDANT'S EXHIBIT E 5

Wireless Telegraphy and Telephony, by Eccles, 1918

Quenched Spark Methods—General Account of the Phenomena. Probably all short spark dischargers set their circuits into oscillation by what is variously called "impact" or "shock" excitation; and the terms "short spark" and "quenched spark" are often taken to be synonymous. Max Wien published in 1906 the first full account and explanation of the phenomenon. His explanation is expressed

diagrammatically in Fig. 110. The two curves (*a*) show the beating oscillations (on a time base) produced in a tuned pair of coupled circuits by a persistent spark in the pri- [fol. 3489] mary; the curves (*b*) show how the quenching of the spark at an early stage leaves the secondary circuit in possession of all the energy and free to vibrate with its natural frequency. The damping of the primary should be at least ten times that of the secondary. Thus quenching ensures singleness of frequency. Quenched sparks are

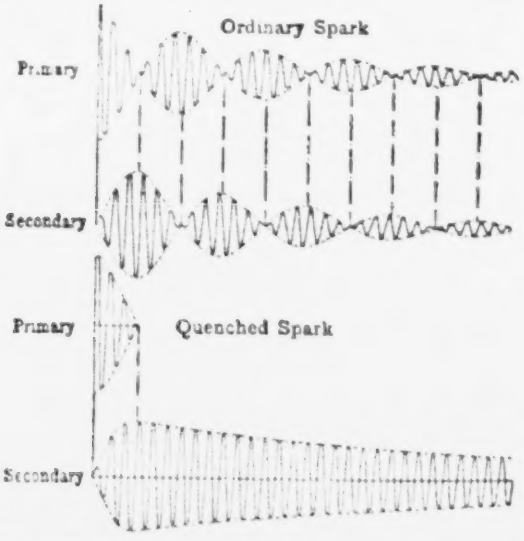

FIG. 110. Diagram of oscillations in coupled circuits. (*a*) Ordinary spark. (*b*) Quenched spark.

easily obtained by putting two electrodes close together and providing for the rapid removal of heat from the region of the spark. If the metal is allowed to get hot some volatilisation takes place and an arc is established. The importance of size of gap is shown by the resonance curves of

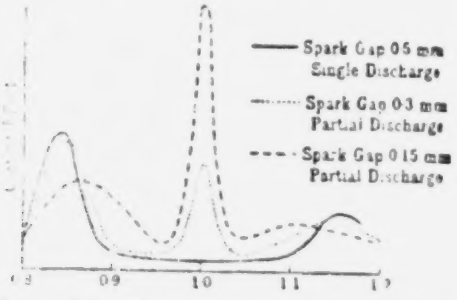

FIG. 111. Curves showing the importance of small gaps in producing a single wave by quenched sparks.

Fig. 111, which were obtained by Wien using a pair of flat parallel circular brass plates.

The condenser used in shunt to short sparks is usually large. It should be so large that its discharge current across the gap is sufficient to annul the supply current and relight the spark in the opposite

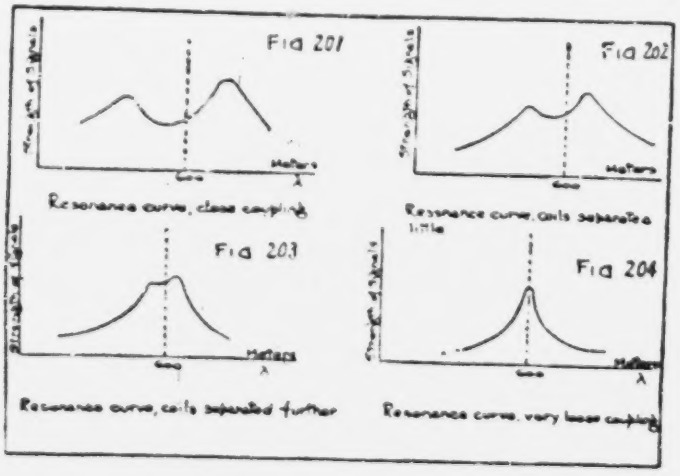
Defendant's Exhibit F-5

Principles Underlying Radio Communication, 1922

In Fig. 204 the signals are strong at or near only one wave length, and diminish rapidly if any of the apparatus adjustments are changed. This is said to be a "pure"



wave.[1] It is desirable to have as sharp a resonance curve as possible, and hence loose coupling is the rule when a plain gap is used. The advantage is that all the power sent out is concentrated into a narrow range of wave lengths, and that receiving stations can tune to the one wave length emitted [fol. 3491] by the transmitting station which they desire to receive and exclude all other wave lengths from other transmitting stations.

Action of the Quenched Gap; Relation to Coupling.—Refer again to the inductively coupled apparatus of Fig. 195 and to the waves of Fig. 154 in Chapter 3. Also refer to the description of the quenched gap in Section 156. The action of the quenched gap is to open the primary circuit, by suppression of the spark at the end of its first train of waves (point *D* in Fig. 154). This prevents the secondary from inducing oscillations in the primary again; that is, from giving energy back to the primary. The secondary or antenna oscillations are not thereafter interfered with by the primary and the antenna goes on oscillating until the energy is all dissipated as waves or heat (see Fig. 155). The length of the train will depend only upon the decrement of the antenna circuit. By reducing the resistance, the dielectric losses, the brush discharges and leakage, the antenna current may be made to oscillate for a comparatively long time, at the frequency for which the set was adjusted. This quenching of the primary avoids the double waves of Figs. 201, 202, and 203, even with close coupling. In fact, the coupling should be close for good operation with the quenched gap. Some care has to be taken in the adjustment of the coupling, but when adjusted properly this gap gives a high pitched, clear note. The wavemeter will readily show when a single sharp wave is obtained (see Section 168), and the sound in the telephone receiver will indicate the proper adjustment for good tone. The quenched gap

[1] The United States radio law requires that if a transmitting station emits more than one wave length, the energy in no one of the lesser waves shall exceed one-tenth of the energy in the principal wave. See the pamphlet, "Radio Communication Laws of the United States," issued by the Bureau of Navigation, Department of Commerce. Copies may be secured from the Superintendent of Documents, Government Printing Office, Washington, for 15 cents each.

is very efficient because the close coupling produces a large current in the antenna.

It is well to note that the principles of operation of the quenched gap and plain gap are exactly opposite. The former aims to stop the primary oscillations quickly, after the secondary has been brought to full activity. The latter aims to keep the primary oscillations going as long as possible, all the time giving energy to the secondary as it is radiated away; the coupling is loose and the primary decrement is kept low. The rapid decrease of the oscillations in a quenched gap circuit is assisted by having a large ratio of capacity to inductance. This has the incidental advantage that the voltages across the condenser and coil are thus kept low.

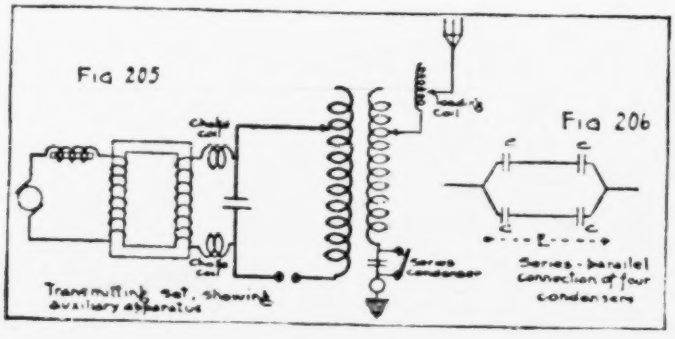
166. *Damping and Decrement.*—If the energy in the antenna circuit is dissipated at too rapid a rate, owing either to radiated waves or heat losses, the oscillations die out rapidly and not enough waves exist in a received train to set up oscillations of a well-defined period in a receiving antenna. Such waves are strongly damped and have a large decrement. They produce received currents of about the same value for a considerable range of wave lengths. Thus selective tuning is not possible.[2] To increase the number of waves sent out in each wave train from the open circuit (that is, to make the oscillations last longer) the resistance of the circuits must be kept low. When using a plain spark gap the coupling between closed and antenna circuits must be small enough not to take energy too fast from the closed [fol. 3492] oscillating circuits. At each condenser discharge the primary has a train of oscillations which at best die out long before another train starts (see Fig. 192); these oscillations are stopped more quickly, however, if the energy is drawn rapidly out of the circuit by the antenna. Close coupling is permissible only when a quenched gap is used (see remarks at the end of the preceding section). With any other kind of gap the secondary is kept oscillating by energy continually received from the primary.

A great many factors contribute to the resistance of the antenna circuit, and this must be kept as low as possible.

[2] See also section 116. The United States radio laws require that no station shall transmit a wave having a decrement exceeding 0.2.

The antenna must have a good low-resistance ground, must use wires of fairly low resistance, and must not be directly over trees or other poor dielectrics. The resistance of the closed circuit particularly must be very low. Heavier currents flow here than in the antenna wires. For this reason the closed circuit wires should be short and of large surface, preferably stranded wires or copper tubing. The condenser should be a good one, free from power loss.

167. *Additional Appliances.*—A number of additional appliances are necessary or desirable for the operation of a



damped wave generating set. The operation is improved by having a variable reactance (iron core inductor) in series with the alternator, to tune the alternator circuit to the alternator frequency. See Bureau of Standards Circular 74, p. 230.

Changes of Wave Length.—In many sets of apparatus it is customary to have connections arranged by means of which different chosen wave lengths, say 300 or 600 meters, can be transmitted without the necessity of a readjustment of the apparatus after each change. An antenna alone without any inductance coil has a natural wave length of its own, dependent upon its inductance and capacity. See Sections 116 and 145. The antenna is usually so designed that its natural wave length is shorter than the wave length to be used, and the wave length is brought up by adding inductance in series or merely by the added inductance of the secondary of the oscillation transformer. In the case of a small antenna, such as that on a small ship, it is necessary to use a large inductance. Since it is desirable to have the coupling loose, a part of the secondary inductance can be in a separate coil called the antenna "loading coil." This loading

[fol. 3493] coil is not coupled to the primary. Fig. 205 shows this arrangement. For a quick change of wave length a single switch is often provided, which, by a mechanism of levers, changes simultaneously the adjustments on all three coils. From these coils are taken out taps over which three switch blades pass, adjusting all the inductances to approximately the values needed for the particular wave length desired, keeping the circuits in resonance and at the proper coupling. For fine adjustments an additional variable inductor may be provided in the primary and in the secondary.

Fig. 205 also shows an arrangement whereby the operator can obtain wave lengths *shorter* than the natural wave length of the antenna by inserting a condenser in series (see Sec. 35) in the antenna circuit. In this case the loading coil will be set at zero turns to diminish the wave length. The condenser inserted must be capable of withstanding high voltages similar to those in the main transmitting condenser. By using a small capacity the wave length can be reduced to approach one-half of the natural wave length. It should not be reduced that much, however, for the radiation is inefficient if the condenser is too small. A zero capacity (an open circuit cutting off the antenna entirely from the ground) would be necessary to produce half-wave length exactly.

Choke coils. Fig. 205 shows also choke coils to prevent the high frequency condenser discharge from getting into the transformer and puncturing the insulation. The coils choke down the radio frequency current but do not obstruct the low frequency charging current from the transformer. They must be specially designed so that they do not have capacity enough to allow the radio-frequency current to pass. They can often be dispensed with. See also Appendix 9, page 578.

168. *Adjustment of a Typical Set for Sharp Wave and Radiation.*—The set is assumed to be an inductively coupled set, arranged as in Fig. 205. The first step in adjusting it to work properly is to tune the closed circuit to the wave length which is to be used. This is usually done by varying the primary inductance, which includes the primary of the oscillation transformer. The primary capacity is usually fixed in value and not readily changed. Manufacturers usually mark on the primary variable inductance

the wave lengths corresponding to various settings. If this has not been done, it will be necessary to determine the wave length by the aid of a wavemeter having in its circuit a sensitive hot-wire ammeter. The wavemeter is placed at a distance of one or more meters from the coil of the closed circuit, and with the set in operation but the antenna circuit opened, the wavemeter coil is so turned that a small current is observed in the wavemeter ammeter. With the wavemeter set at the chosen wave length the closed circuit inductance is varied until resonance is obtained. If no resonance point is found, it is probable that the closed circuit inductance or capacity is either too large or too small. This inductance should be varied and a resonance point will be located after a few trials. It may also be necessary to increase or decrease the number of condensers used.

[fol. 3494] The next process is to adjust the secondary inductance and the coupling to obtain a pure sharp wave; that is, to get as much as possible of the power into the wave length that is to be used. Both primary and secondary circuits are closed and coupled together, using at first a fairly loose coupling unless the spark gap is a quenched gap. The secondary of the oscillation transformer or the antenna loading coil is varied until resonance is obtained, as shown by a maximum reading of the hot-wire ammeter in series with the antenna. This adjustment may be checked with a wavemeter. The wave length at which maximum current is obtained should be the same as the wave length for which the primary was adjasted. The wave meter should not be coupled to the secondary of the oscillation transformer, but to a loading coil or other coil at a distance, or to the ground connection. The coupling is then made closer until two points of resonance appear. It is desirable to have a pure wave; that is, have only one resonance point. Therefore the coupling is loosened until it is certain that there is just one sharp point of resonance. If the set has a quenched gap, the coupling is kept close, and varied only enough to insure a single, sharp, wave. The radiation or maximum current at the desired wave length will not occur when the coupling is tightest, nor will it necessarily occur when the reading of the *an*tenna ammeter is greatest. The condition for efficient transmission is that maximum energy radiation should be secured at the wave length to which the set is adjusted.

It is next necessary to adjust the generator voltage and the length of the spark gap to get maximum current in the antenna at the desired wave length, and a good clear spark tone. The field current of the alternator and the length of the spark gap are adjusted until maximum current and best tone are obtained, the wave length and coupling adjustments being kept fixed. It is often desirable to vary the coupling a little and then repeat this adjustment, since in some cases a small increase of coupling may make it possible to obtain increased antenna current without seriously affecting the sharpness of the radiated wave. For a quenched gap, the coupling adjustment need for maximum antenna current and best tone is very critical.

The first two adjustments mentioned are made for the purpose of obtaining in the circuits resonance to the radio frequency which it is desired to radiate. It is, however, also important to obtain proper tuning with respect to the low audio frequency (perhaps 60 to 1,000 cycles) generated by the alternator. The audio frequency to which the circuit should be tuned to get the best *best* tone and most satisfactory operation is not the frequency supplied by the alternator, but is some 10 per cent to 20 per cent lower than the alternator frequency. The reactances of the transformer and of the rotor of the alternator are very important in determining the audio-frequency tuning characteristics, and for a given transmitting set the transformer and alternator are usually so designed that their reactances will be of the proper magnitudes at the operating fre- [Vol. 3495] quency. If the transformer and alternator do not have the proper reactance, it may be necessary to supply an inductance in series with the alternator field. If such a series inductance is used, its setting to a proper value constitutes a fourth adjustment of a spark set. For a further discussion of tuning to the audio frequency, see Bureau of Standards Circular 74, p. 230, and H. E. Hallborg, Proceedings Institute Radio Engineers, vol. 3, p. 107, June, 1915.

DEFENDANT'S EXHIBIT G-5

Wireless Telegraphy, by Leggett, 1921

Author's Preface

It is a matter for comment that whilst numerous works have been published, and others are still being produced, dealing with the highly important science of Wireless Telegraphy, yet none of these give more than a mere outline of the Quenched-Spark System, a system which has been employed in almost every country throughout the world. In view of its extensive adoption in such countries as the United States of America, Australia, Japan, China, and Germany, and considering that it can for land stations claim to rank with the Marconi System in importance, this lack of literature in England is difficult to understand. It is, however, probably the result of national prejudice, since the system had its origin in Germany, where it was experimented with and established by the Telefunken Co. The history and development are given in detail in the Introductory Chapter, and the efficiency of the Quenched-Spark Gap is so undoubted that its scientific merits cannot be ignored or dismissed by appeals to false patriotism. The original Telefunken System has been developed to such a large extent in other countries, including England, that the Quenched-Spark System, which is its outcome, can now be viewed as an International System.

The Author hopes and believes that the present book fills a distinct gap in wireless literature, as there is no volume at present in English which deals in detail with the Quenched-Spark System, either as manufactured in this or in other countries, or of the original Telefunken System. Much of the apparatus has never previously been illustrated and described in the English language, and much, including very many illustrations, has never yet been published in any country. The Author is indebted to Messrs. Siemens Bros. & Co., Ltd., of Woolwich, for the majority of the photographs from which blocks have been made.

In the matter of block reproduction, at present a very expensive process, the Author wishes to give acknowledgment to the publishers, who have agreed with the writer that in technical descriptions a block is often of far more use than many pages of descriptive matter, and have, in

consequence, spared no expense in the preparation of illustrations.

The Author has had considerable experience of actual manufacture, installation and operation of nearly all the [fol. 3496] apparatus described, and he hopes, therefore; that serious technical errors will not be found in the present volume. In this endeavor to avoid errors the Author has been fortunate in obtaining the assistance of several experts in the reading of the proofs. He wishes to render thanks to Mr. H. Machen, A.M.I.E.E., Chief of the Wireless Department, Messrs. Siemens Bros. & Co., Ltd., Woolwich, for his careful revision of proofs and for many suggestions of improvement, and also for much valuable assistance during his career.

The Author would particularly pay acknowledgment to Mr. J. L. Bale, of Messrs. Chapman & Hall, who has throughout given much assistance to the Author in rendering into book form what was previously a set of technical notes taken over a period of several years.

For further general proof reading, and particularly for suggestions and information regarding aeronautical wireless, the Author wishes to express his sincere thanks to Mr. S. T. G. Andrews, B.Sc. (Engineering). His gratitude is also due to Dr. L. Isserlis, B.A., Mathematical Tripos, and Mr. S. G. Starling, B.Sc., A.R.C.S., Examiner in Physics, London University, who have been kind enough to read the proofs of Chapter II, and offer suggestions.

The chapter on wireless propagation embodies an analogy which the Author has himself found very useful in interpreting wireless phenomena. Whilst not offered as an actual explanation, possibly open to criticism, it should not detract from the more practical portions of the book.

The chapter upon maintenance has been included in order to render the book of greater use to operators of the Quenched Spark System, who are rapidly increasing in number now that a number of well-known shipping lines are fitting many of their new vessels with this system.

Acknowledgment is also due to the "English Mechanic" for permission to reproduce much of the matter of the earlier chapters, which the Author originally wrote for this Journal.

In conclusion, the Author would state that whilst in agreement with the spirit of the extract from the "Elec-

trician" (given on p. vi), he does not himself believe the actual position to be as bad as this extract would imply, but the apparent general backwardness in English wireless may be partly attributed to the mistaken policy of Government Departments in withholding much scientific information obtained during the late War at great expense to the country. A particular example is afforded by the Signals Experimental Establishment Pamphlets which are available to those able to use the Library of the Institution of Electrical Engineers, and doubtless to many commercial firms having foreign connections, but which cannot be purchased by the general public who have borne the expense of their production. In this connection the Author believes Prof. Townsend of Oxford undertook for the military authorities extensive scientific researches showing comparisons between Open-, Quenched-, and Rotary-Spark Gaps. No details of these tests of efficiency, which would un- [fol. 3497] doubtedly be of great assistance to shipowners and others requiring to install new wireless apparatus, have yet been published.

Bernard Leggett.

London, November, 1920.

In Fleming's treatise the achievements of Mr. Marconi and the apparatus of the Marconi Company are dealt with at great length, but it is a matter for comment that the apparatus of this company's greatest competitor, namely, the Telefunken and Quenched-Spark system, receives very scanty notice, and indeed its name does not appear in the index to his book.

Eccles' book is far more general in nature, but as the book is much more restricted in size, his matter on the Telefunken and Quenched-Spark systems is necessarily small.

The sources of information regarding the original Telefunken system are very restricted, especially to those unable to read German. Such restriction of information is purely insular. The average English reader is practically unaware of the existence of any important commercial system of wireless telegraphy other than that of the Marconi Company, and is quite astounded when told of the existence of another system which, outside England and a few of its Colonies, is perhaps for land stations the most extensively adopted by other countries.

Since the original home of the Quenched-Spark system is Germany, national prejudice has, until recently, prevented the full recognition of this important system of wireless telegraphy, in spite of its great scientific merits.

There is, however, only one test of any scientific apparatus, namely, its efficiency. Since the Quenched-Spark Gap has at least twice the efficiency of any other form of spark gap, it is far from patriotic to neglect the possibilities of this system. On the contrary, it is a truer form of patriotism to examine, impartially and scientifically, the merits and demerits of foreign scientific work, German or otherwise, and then to utilise the results of such examination to the furtherance of British science and technology.

. . . . . .

As evidence that the only true test of any scientific apparatus depends upon actual results, the author might mention the following incident described by an English paper, "The China Coast Shipping Gazette," as long ago as 3rd November, 1911.

The English steamer "Brodmore" was in Hankow harbour in distress with a perishable cargo of meat. The skipper, owing to destruction of the land lines by insurgents, was unable to wire to Shanghai for a relief ship to salve his cargo. He approached the British Consul, with a request that a British warship in harbour should be utilised to send a wireless message to Shanghai and was informed that the wireless range of this warship was insufficient for it to do so. Lying in the harbour was the German warship "Leipsig" fitted with Telefunken apparatus. As it was in permanent communication with the German warship "Nurnberg" in Shanghai, the captain of the "Leipsig" [fol. 3498] offered to assist the "Brodmore" skipper by sending his message, the cargo so being eventually salved.

The above mentioned paper noted upon the incident to the following effect: "The system upon which the English Navy depends shows itself in a very bad light, and the English ships are unable to bridge large distances, while the German warships fitted with the Telefunken system are in easy permanent direct communication between Hankow and Shanghai. The German warship 'Leipsig' in Hankow, is, we hear, in permanent communication with the 'Nurnberg' in this harbour, and exchanges regular

. . . . . .

This shows us that, with coupled circuits, which of necessity to avoid radiation of energy upon many wavelengths, we are compelled to adopt, *we obtain in the aerial two oscillations of very different wavelengths having maxima* λ_1 *and* λ_2.

Since, at any instant, a receiving station can only be tuned to one wavelength (the largest λ_2), *the energy of the other*

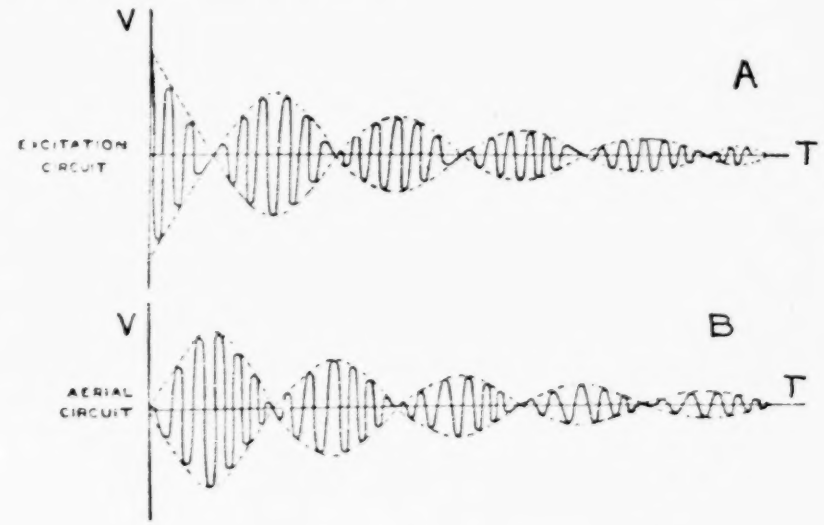


FIG. 13.—Oscillations in open-spark transmitter (Wien).

maximum wavelength λ_1 represented by the shaded area (since energy is proportional to the square of the current) and which is large in proportion to the energy of λ_2, *is totally wasted* and only gives rise to "jamming," or interference, at other neighbouring receiving stations.

The Necessity of Quenching

On pages 46 and 47 we showed by mathematical analysis the existence of two oscillations in a secondary or aerial circuit, since we obtained two different periods of oscillation.

From consideration of resonance, on page 53, we obtained a value for the secondary voltage, which was seen to have two components, each of which represented a distinct oscillation. We also found that the total current in the aerial [fol. 3499] had two components, which explained the double peak of the resonance curve, obtained in practice for coupled circuits.

The actual presence of this dual oscillation can be actually shown by use of the Braun cathode tube.

If this is done we obtain curves for the variation of voltage in the two circuits as follows:

Those familiar with the theory of sound will at once recognize that the aerial and excitation circuits both oscillate with "beats". There are, in each circuit, two oscillations of different periods and damping, which as they agree or differ in phase give rise to electrical "beats" similar to beats obtained with mechanical systems vibrating to produce sound.

Since the energies of the oscillations in each circuit sometimes assist and sometimes oppose each other, we must always have a loss of energy in the latter case.

The forced oscillation in the aerial is produced by the further transfer of energy from the excitation circuit, and, as the latter is an alternating source of current, for short periods we will have the forcing voltage equal zero.

This will allow energy to surge back from the aerial circuit, since the voltage of the latter, owing to the free oscillation, is not zero, and the spark gap will be bridged, so causing a great loss of energy owing to its high resistance, which dissipates the electrical energy as heat and light energy.

Further advance of time permits the oscillations produced in the excitation circuit to again excite the aerial, this cycle continuing until all the energy is dissipated either by radiation from the aerial or by resistance losses at the spark gap.

If we can now discover some means whereby immediately the excitation circuit has first imparted its energy to the aerial circuit, the resistance of the spark gap of the former circuit is made so great that energy surging back into it is unable to bridge the spark gap, all the energy connected magnetically and statically with the two circuits will (neglecting the very small resistance of the aerial circuit) only have one means of dissipation, namely, by useful radiation from the aerial circuit. Since the forced oscillation of the excitation circuit ceases to exist, *all the energy will be radiated on one wavelength, namely, the natural wavelength of the aerial circuit.*

The act of stopping the flow of energy in the excitation circuit is known as "quenching," since it is brought about by preventing or quenching the return spark. Also since all the energy is transferred from the excitation to the

aerial circuit after the passage of a single spark, the aerial circuit is said to be "impact" of "shock excited".

Quenching is best brought about by use of a special form of spark gap described in detail in the next section.

The effects of quenching are very noticeable in practice. [fol. 3500] Considering first the variations of voltage in the two circuits, these are shown as follows:

It will be noticed the oscillations of the excitation circuit are practically non-existent, and that the train of oscillations of the aerial has a very low logarithmic decrement, and therefore a long persistence. Beats do not occur, and there is therefore no waste of energy in beat production.

The aerial oscillations tend therefore to continuous oscillations and the area of the curve they produce, being proportional to voltage (or current), determines the energy. The great increase in aerial energy will be at once recognised, when compared to the oscillation of the aerial when the return sparking is not quenched and beats occur.

Consider now the effect of quenching on the resonance curve.

Curves for oscillations produced by open and Quenched-Spark gaps are given on pp. 334 and 335 of Fleming's "Principles of Electric Wave Telegraphy" from actual experiments by Fleming and Dyke.

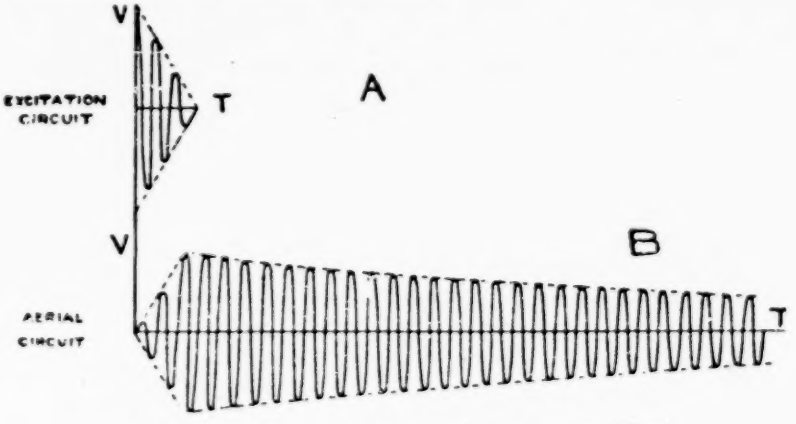

FIG. 14.—Oscillations in quench-spark transmitter. (Wien.)

As, however, unless one recognises the differences in coupling in the original curves, the whole difference between open and quenched gaps is apt to be overlooked, the author has taken the liberty of redrawing them in a series of curves

(Fig. 15), each of which show the open and quenched-gap curves for the same particular degrees of coupling.

In the case of the open-gap curves when quenching does not occur, the curve will be found to have two distinct peaks of very different wavelength and low current value, which is proportional to the energy radiated.

For a coupling of 26 per cent., with the quenched gap there is only one sharply defined peak (the other having

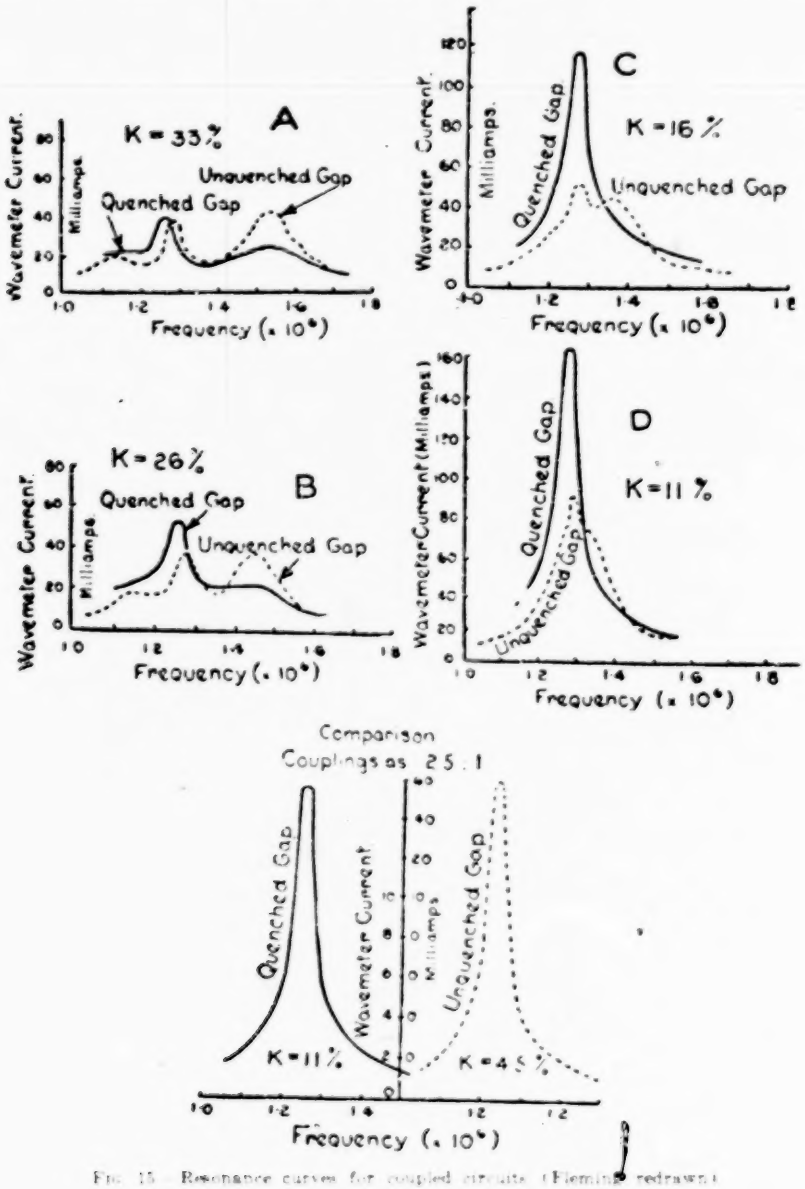

FIG. 15.—Resonance curves for coupled circuits. (Fleming, redrawn.)

nearly disappeared at a coupling of 26 per cent.). Compared with the open-spark curve of similar coupling, its current value is much greater, and therefore more energy is radiated upon a sharply defined wavelength.

In the case of the double peaked open-gap curves, a receiving station can only resonate to one wave length, and [fol. 3501] therefore the energy of the other is totally wasted and only serves to cause interference to other stations.

The last curves of this series show the difference of coupling necessary to obtain the same current effect with open and quenched gaps. These couplings are, according to Fleming, 11 per cent. for the quenched gap as opposed to a much weaker coupling of 4.5 per cent. for the open gap. This means that the coupling must be weakened and therefore a less transference of energy from excitation and aerial circuit takes place, and to render the aerial currents equal [fols. 3502-3505] much greater energy in the prime circuit must be present. According to Fleming's figures it would be presumably necessary to use $\frac{11}{4.5} = 2.5$ times the prime energy to obtain the same aerial energy, i. e., with the quenched gap the efficiency is about 75 per cent. if we take the usual value of 25 per cent. for the open gap, a figure for the quenched gap which *which* has been quenched by its opponents.

To the Commissioner of Patents:

Your Petitioner, Guglielmo Marconi, a Subject of the King of Italy, residing at 18 Finch Lane, Threadneedle Street, in the City of London, England, Electrician, which is his postal address, prays that Letters Patent may be granted to him for the "Improvements in apparatus for "wireless telegraphy," set forth in the annexed specification: and he hereby appoints Frederic H. Betts, Samuel R. Betts, James R. Sheffield *and* Louis F. H. Betts, constituting The Firm of Betts, Betts, Sheffield & Betts, of 120 Broadway, in The City, County and State of New York, United States of America, his attorneys, with full power of substitution and revocation, to prosecute this application, to make alterations and amendments therein, to receive the Patent and to transact all business in the Patent Office connected therewith.

GUGLIELMO MARCONI.

U. S. Revenue Stamp, 25 Cents. W. H. B. Nov. 9, 1900.

[fol. 3519] Cancelled per Sub Spec.

To all whom it may concern:

Be it known that I, Guglielmo Marconi, a Subject of the King of Italy, residing at 18 Finch Lane, Threadneedle Street, in the City of London, England, Electrician, have invented certain new and useful "Improvements in apparatus for wireless telegraphy," of which the following is a Specification:—

The object of this invention is not only to increase the efficiency of the apparatus hitherto employed, but also to so control the action as to cause intelligible communications to be established with one or more stations only out of a group of several receiving stations.

[fol. 3520] In the specification of a former patent No. 586193 a transmitter is described which consists of an induction coil, one terminal of the secondary

circuit being connected to a metal sphere connected to earth and the other to a similar sphere connected to an insulated conductor which generally takes the form of a more or less vertical wire which may or may not terminate or have attached to it a metal body of extended surface, giving it increased electrical capacity.

According to the present invention the vertical wire is connected to earth through the secondary winding of a transformer of a kind suitable for the transformation of very rapidly alternating electric currents and the primary of this transformer is connected to the spheres or terminals of the sparking appliance.

A condenser of suitable capacity is introduced in series with the primary or each end of the primary may be connected to one of the plates of two condensers of suitable capacity, the other plates of which are connected to the sparking appliance.

This device enables much more energy to be imparted to the radiator than heretofore the approximately closed circuit of the primary being a good conserver and the open circuit of the secondary a good radiator of wave energy.

The arrangement works as follows:—

On pressing the key and actuating the induction coil (in order to produce a signal) the condenser in circuit with the transformer is charged and subsequently discharges through the spark gap. If the capacity, the inductance, and the resistance of [fol. 3521] the circuit are of suitable values, the discharge

is oscillatory, with the result that alternating currents of high frequency pass through the primary of the transformer, and induce similar oscillations in its secondary these oscillations being communicated to the elevated conductor.

The circuit of the elevated conductor should be suitably attuned for this purpose.

The effect of these oscillations in the elevated conductor is to inductively affect similar distant conductors if the self induction

and capacity of the said conductors is of a suitable value or values.

At the receiving end a receiver is employed capable of being actuated by electrical oscillations of high frequency such as are described in the specifications Nos. 627,650; 647,007; 647,008; 647009 and 586,193.

The four circuits namely those including the primary and the secondary of the transformer in the transmitter and the primary and the secondary of the transformer in the receiver should be so adjusted as to make the product of the self induction multiplied by the capacity the same in each case that is to say their electrical time period should be the same but they may also be octaves of each other.

In employing this invention to localise the transmission of intelligence to one out of several receiving stations the time period of the circuits at each of these stations is so arranged as to be different from those of the other stations. If the time period of the circuits of the [fol. 3522] transmitting station are varied until they are in resonance with those of one of the receiving stations that one alone out of all the number of receiving stations will respond, provided that the distance between the transmitter and receiver is not too small.

The adjustment of the self induction and capacity of the circuits can be made in any convenient manner those which are preferred being set out in the following description.

Figures 1 and 2 are diagrams of the transmitter and of the receiver respectively, whilst Figure 3 shows a side view and Figure 4 an edge view of a transformer used at the transmitting station and Figures 5 to 8 show various induction coils used at the receiving station.

a is a battery, b a Morse key, c a Ruhmkorff coil the primary of which is in circuit with the battery whilst the terminals of the secondary are connected to the primary d of a transformer one of the connections being through a condenser e, or there may be a condenser in both of the connections. The secondary d' of the transformer is connected to an aerial conductor A which may have at its top a metallic cylinder f and to earth or a capacity E. Between the secondary and the aerial conductor or it might be between the secondary and earth is sometimes inserted an inductance coil g having numerous coils and the connection is such that a greater or less number of [fol. 3523] turns of the coil can be put in circuit, the proper number to use being ascertained by experiment.

The receiver (Figure 2) consists of an aerial conductor A which may have a cylinder f' at its top connected through an inductance coil g' similar to g and through the primary f' of an induction coil to earth or a capacity E: a small condenser h may be inserted in parallel with the primary f'.

Cancelled Per Sub Spec.

The secondary f^2 of the induction coil is divided in the middle and has its inner ends connected to the plates of a condenser f^3 while its outer ends are connected it may be through inductance coils g^2 similar to g to a detector or coherer T: a condenser h' may be inserted in parallel with the detector. The local circuit containing a battery ceil B and relay or telegraph instrument R is connected through choking coils c' c^2 to the plates f^3 of the condenser.

The condensers h h' are preferably in the form of two metallic tubes separated by a dielectric and sliding telescopically on

each other as in this way their capacity can readily be varied with accuracy to tune the circuits.

The following are details of arrangements which have been found to work well.

The cable used for the aerial conductor at either station and for the transformer $d\ d'$ at the transmitting station is in all the examples given composed of seven strands [fol. 3524] of copper wire .889 mm. in diameter. The aerial conductor at the receiving station is in each instance exactly similar to that at the transmitting station for the corresponding tune.

The details of the transformers $d\ d'$ are as follows:

Transformer No. 1. The total length of the primary d is .946 metres and it is bent round a square d^2 of insulating material of which the side is .3048 metres long while the secondary d' consists of two turns or squares one lying on each side of the primary (see Figures 3 and 4). The insulation of both primary and secondary consists of 1.25 mm. of rubber and 1 mm. of jute making a total thickness of 2.25 mm.

Transformer No. 2 is exactly similar to No. 1 except that the total length of the primary d is 1.93 metres.

Transformer No. 3. The primary consists of ten turns of cable wound on a cylindrical core 10.16 cm. in diameter; over this but separated from it by 2 mm. of paper or other insulating material is wound the secondary also of ten turns.

The inductance coils $g\ g'$ are of copper wire 6.25 mm. in diameter wound on a cylinder 10.64 cm. in diameter an interval of 2.28 mm. being left between adjacent turns while the inductance coils g^2 inserted in series with the secondary f^2 of the induction coil at the receiving station are

of copperwire, silk covered, of .19 mm. [fol. 3525] diameter wound on cylinders 3.7 cm. in diameter.

Figures 5 to 8 show details of the induction coils j' j^2.

These diagrams are greatly enlarged half longitudinal sections, but are not strictly to scale. In place also of showing the section of each coil or layer of wire as a longitudinal row of dots or small circles as it would actually appear, it is for simplicity shown as a continuous longitudinal straight line.

Induction coil No. 1—see Figure 5. The primary consists of 3.048 metres of silk covered copper wire .71 mm. in diameter wound in one layer on a core 2.9 cm. in diameter. Insulating material is wound over and on each side of this so as to make a cylindrical core 3.13 cm. in diameter on which is wound the secondary each half consisting of 6.4 metres of silk covered copper wire .19 mm. in diameter joined to 13.41 metres of silk covered copper wire .37 mm. in diameter wound in the same sense as the primary, the thinner wire being over the primary and the thicker being beyond the ends of the primary.

Induction coil No. 2—see Figure 6. The primary j' wound on a core .6 cm. in diameter consists of 100 turns of copper wire .037 cm. in diameter insulated with single silk and coated with paraffin wax. the secondary j^2 is of copper wire [fol. 3525½] .019 cm. in diameter insulated with single silk covering and is wound over the primary commencing in the middle and in the same sense as the primary. Each half of the secondary is in layers of the following number of turns: first layer 77, second 49, third 46, fourth 43, fifth 40,

sixth 37, seventh 34, eighth 31, ninth 28, tenth 25, eleventh 22, twelfth 19, thirteenth 16, fourteenth 13, fifteenth 10, sixteenth 7, seventeenth 3, making 500 in all.

Cancelled Per Sub Spec.

Induction coil No. 3—see Figure 7. The primary consists of 3.048 metres silk covered copper wire .19 mm. in diameter and the secondary 30.48 metres long of silk covered copper wire .1 mm. in diameter wound in one layer on a core 4 cm. in diameter, the primary being in one layer outside the secondary.

Induction coil No. 4—see Figure 8. The primary consists of 3.048 metres silk covered copper wire .37 mm. in diameter wound on a core 2.9 cm. in diameter and inserted in a tube $\frac{3}{4}$ of 4 cm. external diameter on which is wound the secondary of 27.432 metres silk covered copper wire .12 mm. in diameter, the break at the middle of the secondary being over the middle of the primary.

The following tables give the adjustments, those details opposite any tune in the transmitting station table being of course used in connection with those opposite the same tune in the receiving station table.

[Matter enclosed between rules erased in copy.]

(Here follows 1 photolithograph, vide folio 3526)

Transmitting Station.

Tune	Aerial — Conductor	Transformer d d'	Inductance Number of turns of g included	Capacity in microfarads e	Length of spark in millimetres
No. 1	36.576 metres of cable	No. 1	None	.006934	3
No. 2	ditto	No. 1	45	.016395	4

C. H. DUELL,
[THOMAS EWING],*
Commissioner of Patents.

[*Words and figures enclosed in brackets erased in copy.]

Claim 1 is rejected upon the patent to Lodge, 29,505 of 1897, Telegraphy, Circuits and Systems, particular reference being had to figure 7. This patent describes a system of syntonic telegraphy on the induction system. To use the coil e as the primary of the transmitting circuit, as shown in the patent to Marconi, 586,193, July 13, 1897, Circuits and Systems, is deemed unpatentable, especially in view of the fact that in said patent statement is made that tuned circuits may be used.

As to claims 2, 4 and 6, it is required that further and clearer description be inserted in the specification as to what is meant by "persistent oscillator" and "good radiator". Until such requirement is complied with it must be held that there is insufficient basis in the specification to warrant said claims.

Claim 3 is rejected upon the British patent to Lodge, 29,505, of 1897, cited above. To have two associated tuned circuits in inductive relation to each other is deemed unpatentable; see the patent to Pupin, 640,515, Jan. 2, 1900, Circuits and Systems.

Claim 5 is also rejected upon the patent to Lodge cited above. To use step up transformers with the arrangement shown in figure 7 and step down transformers all of which are tuned, is thought to be comprehended by the disclosure of said patent.

[fol. 3532] Claim 7 is rejected upon the patent to Lodge cited above. To use such transmitting device associated with Marconi's transmitting device as disclosed in his patent No. 586,19[5]*, cited above, is deemed unpatentable.

Examiner, Div. 16.

C. D. E.

[fol. 3533] U. S. Patent Office.

In the Matter of the Application of GUGLIELMO MARCONI, for Patent for Apparatus for Wireless Telegraphy. Filed November 10, 1900. Serial No. 36,010.

July 1st.
New York, [March]* 1901.

Hon. Commissioner of Patents,
Washington, D. C.

SIR:

In the above-entitled matter, we authorize and request the cancellation of the Specification and Claims on file down to, but not including, the signatures, and the substitution of the following:

Specification.

To all whom it may concern:

Be it known that I, Guglielmo Marconi, a subject of the King of Italy, residing and having a Post-Office address at 18 Finch Lane, Threadneedle Street, in the City of London, England, Electrician, have invented certain new and useful Improvements in Apparatus for Wireless Telegraphy, of which the following is a Specification:

My invention relates to apparatus for communicating electrical signals, without wires, and by means of Hertz or electric waves

Per F. oscillations, and the object of the invention is to increase the efficiency of the system, and to provide new and simple means whereby oscilla- or electric waves

Per F. tions from a transmitting-station may be lo- one

Per F. calized, when desired, at any selected receiving-

Per F. station or stations [only]* out of a group of [fol. 3534] several receiving-stations.

(Reissue No. 11,913, dated June 4, 1901.)

In my prior United States Patent No. 586,193, I have shown and described the combination, at a transmitting station, of an oscillation-producer, such an induction-coil

[*Words and figures enclosed in brackets erased in copy.]

having one end of its secondary-coil connected to one contact of a spark-producer, and to the earth, and having the other end of the said secondary connected to the opposite contact of the spark producer and to a vertical wire or elevated plate: and I have further shown, as a receiving-station an imperfect contact connected in circuit with a vertical receiving-wire and with the earth.

According to the present invention, the system includes, the combination,

at the transmitting-station, ^ with an oscillation-transformer, of a kind suitable for the transformation of very rapidly alternating currents, of a persistent oscillator and a good radiator, one coil of said transformer being connected between the aerial wire, or plate, and the connection thereof to earth, while the other coil of the transformer is connected in circuit with a condenser, ^ a spark producer

Insert F'

an

Per F. and ^ induction-coil, (constituting the persistent oscillator) controlled by a signalling instrument; the complete system also includes at a receiving-station, an oscillation-transformer, one coil whereof is included between the aerial receiving wire and earth, constituting a good absorber of electrical oscillations, while a device responsive to electric waves, such as

Per F. ^ an imperfect contact, or a device for operating the same, is included in a circuit with the other coil of said transformer.

The system also requires as essential elements thereof, the inclusion in the lines (at both stations) from the aerial conductor to the earth, of variable inductances and the use at both stations of means for varying or adjusting the inductance of the two circuits, at each station to accord with each other. By this arrangement of apparatus, I am able [fol. 3535] to secure a perfect "tuning" of the apparatus at a transmitting-station and at one or more of a number of receiving stations.

Referring to the accompanying drawings: Fig. 1 indicates, diagrammatically, the arrangement of apparatus at a transmitting-station; Fig. 2 indicates, diagrammatically, the arrangement of apparatus at a receiving station; Figs. 3 and 4 are views, plan and side, of the preferred form of transformer at the transmitting station; Figs. 5, 6, 7 and 8, are

diagrammatic views of forms of transformers at the receiving station.

The transmitting-station is provided, under my present invention with a source *a*, of current, electri-
F. E. R. an induction
June 8, 1904 cally connected in circuit with the primary of ^
Per F. [a Ruhmkorff]* coil *c*, and with a circuit-closing key, *b*; or otherwise controlled by a signalling-instrument. In the secondary-circuit of said induction-coil, the spherical terminals, or other contacts, of a spark-
electric wave or
Per F. producer, or other ^ oscillation-producer, are included, with a shunt therefrom, in which shunt is included the primary-coil, *d*, of an oscillation-transformer, such as d^2. A condenser, *c*,—preferably one provided with two telescoping metallic tubes separated by a diaelectric, and arranged to readily vary the capacity, by being slid upon each other— is included in one connection from
induction
Per F. the ^ [Ruhmkorff]* coil to the transformer-winding, *d*.

Cancelled Per C.

A similar, or other, condenser may be included in the return connection between said parts.

The secondary-coil, *d'*, of the transformer, is connected—at
one end—to the earth, E, and at its other end
Insert Y^2 to a vertical wire, A, or an elevate plate*d*, *f* ^.
Y^2

The illustrated arrangement of parts, at a transmitting station, enables much more energy to be imparted to the [fol. 3536] radiator, *f*, the approximately-closed circuit of the primary being a good conserver, and the open circuit of the secondary being a good radiator of wave-energy. My experiments have demonstrated that the best results are obtained, at the transmitting-station, when I use a persistent-oscillator- an electrical circuit of su h a character that, if electromotive force is suddenly applied to it, and the cur-

---

[*Words and figures enclosed in brackets erased in copy.]

rent then cut off, electrical oscillations are set up, in the circuit, which persist, or are maintained, for a long time in the primary-circuit, and use a good radiator (i. e., an electrical circuit which very quickly imparts the energy of electrical oscillations to the surrounding ether, in the form of waves) in the secondary circuit.

In operation, the signalling-key, *h*, is pressed, and this induction

Per F. closes the primary of the ^ [Ruhmkorff]* coil. Current then rushes through the transformer-circuit, and the condenser *c* is charged and subsequently discharges through the spark-gap. If the capacity, the inductance, and the resistance of the circuit are of suitable values, the discharge is oscillatory, with the result that alternating currents of high frequency pass through the primary of the transformer and induce similar oscillations in the secondary, these oscillations being rapidly radiated in the form of electric waves

Per Y. ^ by the elevated conductor.

For the best results, and in order to effect the selection of the station or stations whereat the transmitted oscillations are to be localized, I include, in the open secondary-circuit, of the transformer—and preferably between [fol. 3537] the radiator, *f*, and the secondary-coil, *d'*,—an inductance-coil (*g*, Fig. 1), having numerous coils, and the connection is such that a greater or less number of turns of the coil can be put in use, the proper number being ascertained by experiment.

At the receiving-stations employing my present invention, I prefer to use a receiver such as those described in my several United States Patents, Nos. 586,193; 627,650; 647,007; 647,008; 647,009 and 668,315—capable of being waves or

Per Y. effected by electrical ^ oscillations of high frequency.

Insert Y³.>

Referring to Fig. 2, *f'* indicates a plate or cylinder, not essential at either transmitter or receiver, at the upper end of an elevated conductor A, which is connected to the primary-coil *j'*, of a transformer or induction-coil, and thence to earth, E. In a shunt, around said primary, *j'*, I usually place a condenser, *h*, preferably similar, in construction and operation, to the condenser, *c*. An inductance-coil, *g'*, of

variable inductance, is interposed in the primary-circuit of the transformer, being preferably located between the cylinder, f', and the coil j', and the inductance of said coil may be adjusted, in accordance with the method described by me in my [pending Application, Serial No. ——, filed February 21st, 1901, for]* Letters Patent of the United States, No. 676,332,

Per C. ∧ to harmonize with the inductance of coil, g, at the transmitting-station Fig. 1 of the accompanying drawing) or with that of the coil or coils at one or more of the transmitting-stations included in the communicating-system.

[fol. 3538] The secondary-coil, j^2, of the transformer is preferably wound in two parts, [especially]* ∧ as described in my United States Letters Patent, No. 668,315, dated February 19th, 1901, and the outer ends of said coil are connected in certain cases, through one or more interposed inductance-coils, g^2,—preferably of variable inductance—with the terminals of a coherer, T, or other detecter of electrical oscillations. The inner ends of the split secondary-coil are connected to the plates of a condenser, j^3. A condenser, h^1, is sometimes included in a shunt around the detecter, T. B. is a battery, and R a relay, connected to the condenser j^3, and controlling a telegraphing-instrument or a printing-device. c' and c^2 are choking-coils, preventing oscillations, from the secondary, j^2, running into the battery circuit, and

Per F. thereby confining them to the ∧ [detecter]* wave responsive device.

Substitute F⁴

The four circuits—i. e., the primary and secondary circuits at the transmitting-station and the primary and secondary circuits at any one of the receiving-stations, in the communicating-system—are to be so adjusted as to make the product of the self-induction, multiplied by the capacity, the same in each case, that is to say, their electrical time period shall be the same, or octaves of each other.

[Matter enclosed between rules erased in copy.]

[*Words and figures enclosed in brackets erased in copy.]

In employing this invention to localize the transmission of intelligence at one of several receiving-stations, the time period of the circuits at each of the receiving stations is so arranged as to be different from those of the other stations. If the time-periods of the circuits [of the]* of the trans- [fol. 3539] mitting-station are varied until they are in resonance with those of one of the receiving-stations, that one alone of all of the receiving-stations will respond, provided that the distance between the transmitting and receiving stations is not too small.

The adjustment of the self-induction and capacity of any or all of the four

Per F. [the]* circuits can be made in any convenient manner, and employing various arrangements of apparatus, those shown and described herein being preferred.

In practice, I have found the following preferred details of arrangements of apparatus to work well:

The aerial conductors A, at all stations, and the conductor for the transformer-windings at the receiving-stations, are

Per C. composed of seven strands of copper wire, .889 m m in diameter. The transformer at the transmitting station may be of any of the following forms:

(1) Around a block or core, d^2, preferably a square block (say .17 meters wide) of insulating material is wound [on]* a primary-coil, d, in length .946 metres, while the secondary, d', consists of two turns, or squares, one lying on each side of the primary (see Figs. 3 and 4). The insulation of both primary and secondary consists of 1.25 m m of rubber, and 1 m m of jute, making a total thickness of 2.25 m m.

(2) A transformer, in all essentail respects similar to (1), but with a primary of 1.93

Insert B'. metres.

B'

(3) A transformer having a cylindrical core 10.16 c m. in diameter, and with a primary having ten turns wound thereon; over this, but separated by 2 m.m. of paper—or [fol. 3540] other insulant—the secondary, also of ten turns.

[Insert A.]* Insert D'.>

The inductance-coils, g and g', are, preferably, of copper wire, 6.25 m. m. in diameter, wound on a cylinder 10.64 c. m.

in diameter, with an interval of 2.28 m. m. between adjacent turns. The inductance-coils g^2, at the receiving station, are, preferably, of silk-covered copper wire, .19 m. m. diameter, wound upon cylinders 3.7 C. m. in diameter.

Various forms of induction-coils j', j^2, may be used. Figs. 5, 6, 7 and 8, show details of different forms.

The Figures show, diagrammatically, greatly enlarged longitudinal sections, not strictly to scale. Instead of showing the section of each coil or layer of wire as a longitudinal row of dots, or small circles, as it would actually appear, it is, for simplicity, shown as a continuous longitudinal straight line.

Per C. Referring to Fig. 5, the primary, $[J']^{*}_{\wedge}$ $^{j'}$, preferably consists of 3.046 metres of silk-covered
and
" " copper-wire, say, $_{\wedge}$ 71 m. m. in diameter, wound
of ebonite or other insulating material
" " in one layer on a core $_{\wedge}$ 2.9 c. m. in diameter.

Insulating material is wound over and on each side of this, so as to make a cylindrical core, say 3.13 c. m. in diameter, on which is wound the secondary, each half of which consists of 6. 4 meters of silk-covered copper-wire .19 m. m. in diameter, joined to 13.41 metres of silk-covered copper-wire, .37 m. m. in diameter, wound in the same
sense
[wire]$^{*}_{\wedge}$ as the primary, the thinner wire being over the primary and the thicker being beyond the ends thereof.

[fol. 3541] The form of induction-coil shown in Fig. 6, has a primary of one hundred turns of copper wire .037 c. m. in diameter, wound on a core, j, (2.9 c. m. in diameter), with a single silk-covering and coated with paraffin wax; the secondary j^2, is of copper wire, .019 in diameter insulated with a single silk covering, and is wound over the primary, commencing in the middle and in the same way as the primary. Each half of the secondary is in layers of the following number of turns:—first layer, 77 turns; second layer, 49 turns; third layer, 46 turns; fourth layer, 43 turns; fifth layer, 40 turns; sixth layer, 37 turns; seventh layer, 34 turns; eighth layer 31 turns; ninth layer, 28 turns; tenth layer, 25 turns; eleventh layer, 22 turns; twelfth layer, 19 turns, thirteenth layer, 16 turns; fourteenth layer, 13 turns; fifteenth layer, 10 turns; sixteenth layer, 7 turns; and seventeenth layer, 3 turns—making 500 turns in all.

A third form of induction-coil—shown in Fig. 7—has a primary of 3.048 metres of silk-covered copper-wire, .19 m. m. in diameter, and a secondary of 30.48 metres of silk-covered copper wire, .1 m. m. in diameter, wound in one layer on a core 4 c. m. in diameter, the primary being in one layer outside of the secondary.

The fourth form of induction-coil is shown in Fig. 8. Its primary consists of 3.048 metres of silk-covered copper wire, .37 m. m. in diameter, would on a core 2.9 c. m. in diameter, and inserted in a tube, j^x, of 4 c. m. external diameter, on which is wound the secondary of 27.432 metres of silk covered copper wire, .12 m. m. in diameter, the break at the middle of the secondary being over the middle of the primary.

Cancelled [Insert A^2.]* Insert C'.>

[fol. 3542] The following tables give preferred adjustments, those details opposite any tune in the transmitting station table being, of course, used in connection with those opposite the same tune in the receiving-station table.

Transmitting Station

It will be observed that both the transmitter and the receiver are the same for tunes 1 and 2, and that when the capacity of the condenser, c, is varied, the two stations can be brought into tune by including forty-five turns of each of the coils g, g', and by introducing a condenser, k', of small capacity, in parallel with the coherer, T. Similarly, the transmitter and receiver are the same for tunes 3 and 4, and when the capacity of c is varied, the stations are

[fol. 3544] tuned by including one hundred turns of each of the coils g and g', and by also including the coils g^2.

While I have herein shown and described details of construction and of arrangement found by me to be useful, yet I do not wish to be understood as confining my Claims thereto; obviously modifications, which are within my invention, will readily suggest themselves to skilled persons.

What I claim is:

Sub. B^2

---

1. A system of electric wave telegraphy, in which both the transmitter and the receiver contain a two-circuit oscillation-transformer, the time period of electrical oscillations in the four circuits of the two transformers being the same or harmonics of each other, substantially as described.

2. A system of electric wave telegraphy, in which both the transmitter and the receiver contain a two-circuit oscillation-transformer, one circuit of which is a persistent oscillator and the other a good radiator or absorber of electrical oscillations, substantially as described.

3. A system of electric wave telegraphy in which both the transmitter and the receiver contain a two-circuit oscillation-transformer, one circuit of which is a persistent oscillator and the other is a good radiator or absorber of electrical oscillations, all four circuits having the same time period or being harmonics of each other, substantially as described.

Hon. Commissioner of Patents, Washington, D. C.

SIR:

In the above-entitled matter, we authorize and request the following amendment of the substitute Specification, filed July 1st, 1901;

Page 8, after line 2, please insert the following:

Sub. D'. A' [Sub. B'].* Cancelled

A' "(4). The totai length of the primary d is 1.50 "metres, and it is bent round a square of insulating "material d^2, of which the side is .3048 metres long, "while the secondary d' consists of six turns or "squares, each lying on each side of the primary in "one layer. The insulation of both primary and sec- "ondary is the same as in No. 1."

Per D.

"(5). The primary consists of ten insulated wires each 1.5 metres long, wound side by side in one layer "and connected in parallel, each wire making one

"turn on a square frame, similar to that described "for transformer (4). Over the primary layer is "put a covering of paper, 1 m. m. thick, and upon "this is wound 48.64 metres of wire. The winding "is arranged in layers, the number of turns in each [fol. 3551] "successive layer being, in the first layer "(that nearest the primary), nine; in the second, "eight; in the third, seven; in the fourth, six; in the "fifth, five; in the six, two. The insulation is the same "as No. 1.

"(6) The primary consists of seven wires, wound "side by side, each wire making one turn on a square "frame as used for transformer No. 4. The seven "wires are joined in parallel and the length of each "is 1.50 metres. Over this primary layer is wound "a secondary 30.4 metres long, the winding being ar- "ranged in layers, the number of turns in the suc- "cessive layers being, in the first layer, seven turns; "in the second, six; in the third, five; in the fourth, "four."

"The transformers may be placed in an oil-bath, "especially if the turns are at all numerous."

Page 9, after the last line, please insert the following:

Per D.

A^2 "A fifth form of induction-coil may have a sec- "ondary consisting of 73.15 metres of wire wound, in "one layer, on a tube 5 cms. in diameter; said sec- "ondary being at its middle point, the wire being "12 m. m. in diameter, single silk-covered. There are "preferably two primaries, each consisting of 2.75 "metres of wire .7 m. m. in diameter wound on tubes "6.5 cms. external diameter. The two primaries are "placed symmetrically, side by side, one over each "half of secondary, and joined in parallel."

Sub. C.

"A sixth form of induction-coil, may have a sec- "ondary consisting of 48.64 metres of single silk- "covered copper-wire, .37 m. m. in diameter, wound "on a tube of 9.6 cms. diameter, in one layer, and is "cut at its middle point. Symmetrically over the

"middle portion of the secondary is wound the pri-
"mary 3.64 metres long, of wire .7 m. m. diameter,
"single silk-covered."

"A seventh form of induction-coil, may have a
"primary consisting of four wires, each 3.04 metres
"long, wound in four layers and joined in parallel,
"the layers being one under the other. The pre-
[fol. 3552] "ferred wire is .71 m. m. in diameter in-
"sulated with a single covering of silk. The second-
"ary, which is wound on a tube 3.3 cms. external
"diameter, consists of 21.24 metres of wire, .12 m. m.
"diameter, insulated with a single covering of silk.
"The secondary is divided at its middle point, and
"the primary is placed symmetrically inside of the
"secondary."

Page 11, before the paragraph commencing "It will be observed", please insert the following paragraph:

Cancelled Per C.

A' "Note. In tune No. 9, a small condenser, having
"an approximate capacity of .00008 microfarad, is
"inserted between the lower end of the receiving
"aerial conductor and the induction-coil".

Washington, D. C., August 12, 1901.
Mailed " " "

Guglielmo Marconi, c/ Betts, Betts, Sheffield & Betts, 120 Broadway, New York, N. Y.:

Please find below a communication from the Examiner in charge of your application No. 36,010, filed Nov. 10, 1900, for Apparatus for Wireless Telegraphy.

F. I. Allen [Thomas Ewing],* Commissioner of Patents.

In response to the amendments of July 3 and 8, 1901, the following action is had:

In the first paragraph of page 4 of the specification the definitions of persistent oscillators and good radiators are not sufficient. In general, a circuit which is a persistent oscillator is a poor radiator of electro-magnetic waves, and inasmuch as applicant states that his aerial circuit is the same in period as the primary circuit in which the oscillations are generated, it appears that said aerial circuit would likewise be a persistent oscillator and therefore a poor radiator. Applicant is required to further explain this feature of his invention, and accordingly claims 2, 3, 7 and 8 are objected to.

It is suggested that the word "pending" be cancelled at the end of the sixth line from the bottom on page 5.

It is asked whether the unit be the centimeter or inch used in giving the diameter of the wire as mentioned in line 15 of page 7.

[fol. 3554] J', used in the first paragraph of page 8 should be *j'*. It is thought also that in the third line of the same paragraph 71m. m. is an error.

It is thought that a circuit attuned to a certain frequency will not respond to the current of frequencies which are harmonics of the fundamental to which the circuit is attuned. Consequently, claim 1 is objected to.

Claim 11 is objected to as alternative in form, having both the oscillation producer and imperfect contact as elements in the primary circuits, whereas, by the limitation, the condenser in shunt around the primary coil limits the claim in the structure shown in figure 2, where no oscillator has been shown.

Claims 16 and 17 are not patentable inasmuch as they are drawn to an employment or use which is not comprehended in the patent statutes as patentable matter.

Claim 16 is further objectionable by the use of the phrase "and therefore the persistent oscillator" which is argumentative in form.

G. C. Dean, Examiner Div. 16.

December 6th
New York, [October]* , 1901.

Hon. Commissioner of Patents, Washington, D. C.

SIR:

The Examiner's letter of August 12th has been received.

We authorize and request the following amendments of the substitute Specification and Claims:

Page 7, line 26, after "metres", erase the period, and add the following:

B⁵. "and the core or block on which both primary and secondary are wound is .3048 metres wide".

Pages 8, line 4, before "with", insert the following: "wound on a cylinder 10.64 C.M. in diameter".

Same page, line 25, before "wound", please insert,

(not entered) (repetition) "joined to 13.41 metres of silk-covered copper wire, .37 m. m. in diameter.

Please substitute the following in place of the paragraph beginning "(4)", and ending" in No. 1", page 1 of the Amendment dated July 5, 1901;

[fol. 3556] Per D

B⁷. "(4). The total length of the primary *d* is 1.50 "metres, and it is bent round a square of insulating "material *d*², of which the side is .3048 metres long, "while the secondary *d'* consists of six turns or "squares, three lying on each side of the primary in "one layer. The insulation of both primary and sec- "ondary is the same as in No. 1."

[Matter enclosed between rules erased in copy.]

[*Words and figures enclosed in brackets erased in copy.]

Cancel claims 1, 2, and 3, and substitute the following:

Cancelled per C

B². "1. A system of electric wave telegraphy, in which the transmitter and the receiver each contains an oscillation-transformer, the time period of electrical oscillations in all the circuits of the transformers being the same or harmonics of each other, substantially as described.

2. A system of electric wave telegraphy, in which the transmitter and the receiver, each contains an oscillation-transformer, one circuit of which is a persistent oscillator and the other a good radiator or absorber of electrical oscillations, substantially as described.

3. A system of electric wave telegraph, in which the transmitter and the receiver each contains an oscillation-transformer, one circuit of which is a persistent oscillator, and the other a good radiator of electrical oscillations, all circuits having the same time period or being harmonics of each other, substantially as described."

[Matter enclosed between rules erased in copy.]

Cancel Claim 8, and substitute the following:

Cancelled per C

B³. "8. In apparatus for communicating electrical signals, the combination, with an oscillation-transformer, at a transmitting-station, of an electrical circuit, containing the primary of the oscillation transformer, and a condenser; a signalling instru [fol. 3557] ment controlling the oscillator; and an open circuit, constituting a good radiator, and containing the secondary of the oscillation transformer and a variable inductance, substantially as and for the purpose described."

[Matter enclosed between rules erased in copy.]

Claim 9, line 9, change "effected", to read "affected".
Claim 10, line 9, change "effected", to read "affected".
Cancel Claim 11, and substitute the following:

Cancelled per C

B⁴. "11. At a station employed in wireless telegraphy, the combination, with an oscillation-transformer, of an open circuit comprising an aerial conductor connected with a variable inductance; a connection from said inductance to one coil of the transformer; a connection from the other end of said coil to capacity which may be the earth; a shunt around said coil and containing a condenser; and electrical connections from the other coil of the oscillation-transformer to means affected by electrical oscillations, substantially as and for the purpose described."

[Matter enclosed between rules erased in copy.]

Claim 16, lines 1 and 2, erase "employment", and substitute "combination". Same Claim, line 6, erase "therefore", and substitute "constituting". Same Claim, line 8, erase "therefore", and substitute "constituting".
Cancel Claim 17, and substitute the following:

Cancelled per C

B⁵. "17. In a system of electric wave telegraphy, the combination, at a transmitting-station, of a closed circuit comprising a persistent oscillator and an open circuit comprising a radiator, the product of the effective capacity and effective inductance in each of the two circuits being the same, substantially as described.

[Matter enclosed between rules erased in copy.]
[fol. 3558] Add the following claims:

Cancelled Per C

B⁶ 18. The method of communicating intelligible signals by tuned Hertz oscillations, consisting in adjusting the product of effected inductance in the oscillation-producing circuit and in the radiating cir-

cuit at a transmitting-station of a wireless telegraph apparatus, so as to be substantially the same, substantially as described.

19. The method of communicating intelligible signals by tuned Hertz oscillations, consisting in adjusting the time periods of electrical oscillations in the oscillating-producing circuit and in the radiating circuit at a transmitting station of a wireless telegraph apparatus, so as to be the same or harmonics of each other, substantially as described.

[Matter enclosed between rules erased in copy.]

The Examiner's letter requires fuller definitions of "persistent oscillators" and "good radiators", as found on page 4 of our substitute Specification, and criticises our statement that when the primary circuit is a persistent oscillator, at the transmitting-station, the aerial-circuit is a good radiator. The Examiner apparently bases this criticism that if the time-periods of the primary and aerial circuits are the same, the aerial would be a persistent oscillator and therefore a poor radiator.

In response to this, we would state that the statement made by Mr. Marconi is correct, and is based upon the known fact that vibratory body can be set into vibration either by its fundamental note or by any harmonic. A cir- [fol. 3559] cuit attuned to a certain frequency which is a harmonic of its own, just as a violin string can be set in motion by a tuning-fork which is sounding the first harmonic. Hence, if two electrical circuits are associated with one another, one being a persistent oscillator and capable of storing up a large amount of electrical energy because it has a large capacity, this can be associated with another circuit having the same time-period of vibration but which may be more or less a good radiator according to its form. The radiative power of the circuit may be altered by suitably proportioning the aerial without changing the time-period which depends upon its capacity and self-induction. The radiative power is independent of the time-period. In point of fact, two circuits may have the same time period but very different radiative power.

An early allowance is requested.

Respectfully Submitted, Betts, Betts, Sheffield & Betts, Attorneys for Applicant.

Mailed " " "

Guglielmo Marconi, Care, Betts, Betts, Sheffield & Betts.

Guglielmo Marconi, Care, Betts, Betts, Sheffield & Betts, 120 Broadway, New York, N. Y.

Please find below a communication from the Examiner in your
charge of [the]* application [of]* filed Nov. 10, 1900, Ser. no. 36,010, for Apparatus for Wireless Telegraphy.

F. I. Allen, Thomas Ewing, Commissioner of Patents.

This case has been considered as amended Dec. 9, 1901.

Applicant's argument has been carefully considered and though difficult of interpretation by reason of grammatical defects, and also because of what seems to be a discontinuity of idea, it is correctly or otherwise interpreted by the examiner to mean that the fundamental of the aerial conductor is a harmonic of the local primary or *vice versa*, and that such a relation necessarily requires that the vibrating body of fundamental periodicity have constants such as cause it be a persistant oscillator and the aerial conductor electrical constants which make it necessarily a good radiator.

[*Words and figures enclosed in brackets erased in copy.]

The possibility of such a construction having been clearly set out on pages 7 and 8 of the Work of Hertz, by Oliver Lodge, The Electrician Company, London, 1894, and applicant's theory and explanation in the original and in the substitute specification being in accord with Lodge's statements, it is decided that the objections raised heretofore were not well taken and all further explanation is waived.

The original specification on page 2, line 28, having described the closed circuit primary as a "good conserver", it is believed that the substitute specification was not incor- [fol. 3561] rect in describing the closed circuit primary as a persistent oscillator as the two terms are synonymous.

The original specification has been carefuly compared with the substitute specification of July 3, 1901, and it is found that both describe three forms of oscillation transformers and four forms of induction coils. The amendment of July 8th inserts in the specification a description of three more transformers, namely 4, 5 and 6, and three additional induction coils, namely 5, 6 and 7, as well as a small condenser which may be inserted between the lower end of the receiving aerial and the induction coil. The amendment of Dec. 9, 1901, cancels the description of transformer 4 and inserts in lieu thereof another description of the same. The original specification describes six tunes while the substitute specification, after setting out the constants of said six tunes, adds thereto the constants of three additional ones, namely 7, 8 and 9. If the specific modifications of these transformers and inductions coils are merely special cases, clearly deducible from the principles and illustrations found in the original specification they must be held to constitute an unnecessary amplification of what is already sufficiently disclosed. If on the other hand, they have some added value or significance they involve new matter and are therefore inadmissible for that reason. It is noted that these modifications were not added until after the publication of applicant's British patent No. 7777 of 1900, about the 1st of May, 1901, which described the same.

The amendment of Dec. 6, 1901, orders an insertion after "with", line 4 of page 8, but the word "with" is not found in said line.

[fol. 3562] Page 3, lines 25 to 26, refers to a condenser similar to c which it is stated may be included in the return connection between the parts referred to in the preceding

sentence. This modification should be illustrated if the description is to be retained.

Page 5, line 22 cancel "pending".

Page 7, line 15, insert mm after .889.

Page 8, line 18, change J' to j'. Line 20, change 71 to .71. Same line, after "core" insert the material of which the core is formed.

Page 9, fifth line from the bottom, after "tube" insert the material of which the tube is formed.

The tables are indefinite because the fourth column of the first table in giving the constants of the tunes 1, 3, 5 and 6, seem to imply that there is no inductance in the circuit, whereas it is probably meant that all of the turns of g have been cut out; and because the second table in the last column thereof in giving the constants of tunes 1, 2 and 3 seem to imply the same thing.

Claims 4, 9, 10, 11, 12, 13, 14 and 15 are rendered objectionable by the argumentative phrase "capacity which may be the earth". It is not the province of the claims to explain the terms thereof, but explanation of these terms should be given in the specification. The words "which may be the earth" should be cancelled.

Claim 10 is objected to because it is alternative both in substance and in form because it covers either the transmitter or the receiver. This double meaning is given to it by the 8th line thereof.

Claims 18 and 19 cannot be considered as they are drawn to a method. Division is required under Rule 41.

The following references are cited in rejecting the claims:

[fol. 3563] British patents to

Thompson, 22020, Nov. 3, 1899.
Braun, 5104, Mch. 8, 1899;
Braun, 1862, Jan. 26, 1899;
Braun, 1863, Jan. 26, 1899.

Telegraphy, Wireless,

all of which show oscillation transformers, the primaries of which are persistent oscillators, while the secondaries are good radiators; the British patents to

Brown, 14,449, July 13, 1899.

and the American patents to

Lodge, 609,154, Aug. 16, 1898,
Marconi, 627,650, June 27, 1899,
Telegraphy, Wireless,

which show that it is old to tune a receiver to a transmitter; and the patents to

Marconi, 647,007, Apl. 10, 1900;
Marconi, 647,008, Apl. 10, 1900;
Marconi, 647,009, Apl. 10, 1900;
Marconi, 668,315, Feb. 19, 1901, filed July 17, 1900,

which show that it is old to provide a receiver with an oscillation transformer, one circuit of which is a persistent oscillator and the other a good absorber of electrical oscillations.

Claim 1 is rejected on the first set of references cited because in each of the systems therein set out "the time period of *electrical oscillations* in all the circuits of the transformers" may be the same, or the oscillations of the secondaries may be harmonics of the primaries. This claim covers a very different structure from that called for by claim 3. The statement above quoted from claim 1 does not imply tuning of the circuits. By forced oscillations the time periods would be the same in any of the patents cited against the claim. The claim is further indefinite because it states that the oscillations may be the same or harmonics of each other, but it is not known whether it is [fol. 3564] meant that the secondary of the transmitter and both primary and secondary of the receiver are harmonics of the primary of the transmitter, or whether the primary and secondary of the transmitter have the same period and the primary and secondary of the receiver are harmonics of the same, or whether they are all the same.

Claim 3 correctly covers the disclosure of the specification by setting out that "all *circuits* have the same time period", which of course can only be accomplished by proportioning capacity and inductance, that is by tuning. The claim is met by the first group of references, which show the oscillation transformer &c., in view of the fact that the second group of references shows that it is old to tune a receiver to a transmitter. It is considered that it would not involve invention in view of the latter patents to tune the two circuits of the transmitter to each other, or to tune the two cir-

cuits of the receiver to each other, the two pairs being in tune. This claim is furthermore indefinite for the reason set out in connection with claim 1.

Claim 2 is rejected on the first group of references taken in connection with the four patents to Marconi last cited. The claim calls for nothing more than the use of these receivers of Marconi with the transmitters shown in the British patents to Thompson and Braun.

Claim 4 is indefinite because of the last five lines thereof. By changing the punctuation marks, that is, by changing the comma after "inductance", in the third line from the end, to a semicolon and by cancelling the comma after "end" in the same line, it is readable on figure 1. As the claim stands at present it calls for the inductance g between the secondary d' and the earth. The claim should be rewritten. [fol. 3565] Claim 7 is rejected on Thompson or the three patents to Braun cited.

Claim 8 is incomplete without the oscillator. This oscillator is merely referred to incidentally instead of being made an element of the claim. The claim, however, is rejected on the references cited against claim 7.

Claim 11 is incomplete without including positively "means affected by electrical oscillations" which as the claim stands is merely brought in by inference as an element.

Claims 16 and 17 are rejected on the references cited against claim 3.

G. C. Dean, Examiner, Div. 16.

Am'dt C. & Aff.

Filed May 1, 1902

United States Patent Office

In the Matter of the Application of GUGLIELMO MARCONI, for Apparatus for Wireless Telegraphy, Serial No. 36,010, Filed November 10, 1900

New York,
April 28th, 1902.

Hon. Commissioner of Patents, Washington, D. C.

SIR:

In the matter of the above-entitled Application, we authorize and request the following amendments to the Specification and Claims:

Page 2 of the amendment of July 5, 1901, cancel lines 24 to 32, inclusive, and substitute the following:

C". "Other forms of transformers which may be em-
"ployed by me are described and claimed in my Brit-
"ish Patent No. 7,777 of 1900".

Page 3 of said amendment of July 5, 1901, cancel lines 1 to 12, inclusive.

(Not entered repetition.)

Specification, page 8, line 5, before "with" insert "wound on a cylinder 10.64 cm. in diameter".

Page 3, lines 24, 25 and 26, cancel the sentence beginning "A similar", and ending "said parts".

Page 5, line 22, cancel "pending".

Page 7, line 15, insert "mm." after ".889".

Page 8, line 18, change "J" to read "j". Same page, [fol. 3567] line 21, change "71" to read "and 71". Same line, after the word "core", insert "of ebonite or other insulating material."

Cancel Claims 1, 2, 3, 4, 7, 8, 11, 16, 17, 18 and 19.

Renumber Claim 5 to read 9.

Renumber Claim 6 to read 10.

Renumber Claim 9 to read 11.

Renumber Claim 10 to read 12.
Renumber Claim 12 to read 13.
Renumber Claim 13 to read 14.
Renumber Claim 14 to read 15.
Renumber Claim 15 to read 16.

Claim 13 (new number), line 6, cancel "which may be the earth".

Claim 15 (new number), lines 5 and 6, cancel "which may be the earth".

Claim 16 (new number), line 6, cancel "which may be the earth".

Please insert the following Claims:

Sub D[5]

C[3]. "1. At a transmitting-station in a system of wireless telegraphy, the combination of a transformer whose secondary is connected to an open circuit including a radiating conductor at one end and capacity at the other end, and whose primary is connected to an oscillation-producing circuit which includes a condenser, the oscillation period of the two circuits being in accord with each other, substantially as described.

"2. At a transmitting-station in a system of wire-[fol. 3568] less telegraphy, the combination of a transformer whose secondary is connected to an open circuit including a radiating conductor at one end and capacity at the other end, and whose primary is connected to an oscillation-producing circuit which includes a condenser, and means for adjusting the oscillation period of the two circuits connected with the transformer to bring them into accord with each other, substantially as described.

Sub D[5]

C[3]. "3. At a transmitting-station in a system of wireless telegraphy, the combination of a transformer whose secondary is connected to an open circuit including a radiating conductor at one end and capacity at the other end, and whose primary is connected to an oscillation-producing circuit, and an adjustable

condenser located in the last named circuit, substantially as described.

"4. At a transmitting-station in a system of wireless telegraphy, the combination of a transformer whose secondary is connected to an open circuit including a radiating conductor at one end and capacity at the other end, and a variable inductance located in the said circuit, the primary of the transformer being connected to an oscillation-producing circuit which includes a condenser, substantially as described.

"5. At a transmitting-station in a system of wireless telegraphy, the combination of a transformer whose secondary is connected to an open circuit of a radiating conductor at one end and capacity at the other end, a variable inductance located in the said circuit, the primary of the transformer being connected to an oscillation-producing circuit, and an adjustable condenser located in the last-named [fol. 3569] -cuit, substantially as described.

"6. At a station employed in a system of wireless telegraphy, the combination of a transformer whose secondary is connected to an open circuit of an aerial conductor at one end and capacity at the other end, and whose primary is connected to a closed circuit which includes a condenser, the oscillation period of the two circuits being in accord with each other, substantially as described.

Sub. D[2]

6[2]. "7. At a station employed in a system of wireless telegraphy, the combination of a transformer whose secondary is connected to an open circuit including an aerial conductor at one end and capacity at the other end, and whose primary is connected to a closed circuit which includes a condenser and means for adjusting the oscillation period of the two circuits connected with the transformer to bring them into accord with each other, substa*ton*tially as described.

"8. A system of wireless telegraphy, in which the transmitting-station and the receiving-station each contains an oscillation-transformer, one circuit of

which is a persistent oscillator and the other a good radiator of electrical oscillations, the oscillation period of the circuits at the other station, substantially as described."

[Matter enclosed between rules erased in copy.]

[fol. 3570] Argument

With reference to the position of the Examiner that it would not involve invention, in view of the Patents of Marconi which describe the desirability of tuning a distant receiving instrument so as to correspond with the tune of a transmitting instrument, to tune the two circuits of the multiple-circuit transmitter to each other or to tune the two circuits of a multiple-circuit receiver to each other, we would respectfully answer as follows:

It is very plain that the necessity or desirability of tuning the two circuits of a transmitter to each other or making them accord to each other in their natural period of oscillation, is not an obvious suggestion, from prior descriptions, of desirability of tuning a transmitter to a receiver, as is seen from the fact, although the English Patent of Thompson, No. 22,020 of 1899, describes a two-circuit transmitter, yet the inventor makes not the faintest suggestion of the desirability of having the periods of oscillation accord with each other, and although Mr. Marconi himself, in his Patent No. 627,650, describes a two-circuit receiving instrument, yet he did not make any suggestion that it would be of advantage to make the periods of oscillation of the two circuits accord.

As a matter of fact, the desirability and utility of such an arrangement did not occur to him.

Practical experience has, however, demonstrated that the expedient of making the periods of oscillation of the two circuits, both of the transmitter and the receiver, accord [fol. 3571] with each other, is of very high importance; and in view of the fact that the art of wireless telegraphy is as yet commercially in its infancy, and the proper conditions for effective transmission can only be ascertained by most careful and intelligent experimentation, it would seem clear that this feature of the present invention is not one which was at all obvious to people skilled in the art, and, in fact, was not obvious to the most learned experimenters in this particular art.

We trust, therefore, that the objection will be reconsidered.

With reference to the Examiner's rejection of the Application upon reference to the British Patents to Braun and Thompson, we submit herewith an affidavit of Mr. Marconi, which shows that Dr. Braun's invention did not contemplate the possibility of bringing the two circuits at each station into accord with each other, much less the bringing of two stations into accord, each station containing two circuits. Mr. Marconi's affidavit also deals with the Examiner's rejection upon reference to the prior Marconi patents, and points out that those patents do not speak of or show the two circuits arranged to be brought into accord with each other.

An early allowance is requested.

Respectfully submitted, Betts, Betts, Sheffield & Betts, Attorneys for Applicant.

[fol. 3572]

Serial No. —

Paper No. 5

Amendment

Filed —— —, 190-

UNITED STATES PATENT OFFICE

Room 91

In the Matter of an Application of GUGLIELMO MARCONI for Apparatus for Wireless Telegraphy. Serial No. 36010. Filed November 10, 1900

UNITED STATES OF AMERICA,
Southern District of New York (ss):

Guglielmo Marconi, being duly sworn, deposes and says as follows:

I am the Applicant named in the above entitled application.

I have carefully read the letter from the United States Patent Office, under date of February 11, 1902, rejecting the claims of my Application upon reference to British Patents No. 22020 to Thompson of 1899, No. 5104 of 1899, No. 1862 of 1899 and No. 1863 of 1899, all granted to Braun, upon

British Patents 14449 of 1899 to Braun and 10153 of 1899 to Wilson, the United States Patents to Lodge 609,154, Marconi 627,650, Marconi 647,007, Marconi 647,008, Marconi 647,009 and Marconi 668,315.

The invention of my above entitled application 36019, relates to the improvement in a system of wireless telegraphy, consisting of the combination, at a station, of a transformer whose secondary is connected to an open circuit of an aerial [fol. 3573] conductor at one end, and to a capacity at the other end, and whose primary is connected to a closed circuit which includes a condenser, the oscillation period of the two circuits being in accord with each other.

I am well aware that the employment of a double circuit transmitting apparatus has been described in the British Patents of Thompson and Braun, yet it is perfectly apparent from the statements in those patents that the inventor (Dr. Braun) did not even know or understand *why* the use of double circuits, inductively connected through coils of a transformer, was advantageous. Much less did he understand that there was or could be any advantage in making the two circuits of such inductance and capacity as to have a natural period of oscillation in accord with each other.

I did not myself appreciate the necessity or desirability of such a construction at the time that I invented the two-circuit receiving apparatus described in the United States Patent No. 627,650, and the discovery made by me that the operation of the instrument was greatly improved and its capacity for transmitting and receiving messages at long distances greatly enhanced by causing the circuits to be in accord, was something which was impossible to ascertain, or even to guess at, without careful experimentation.

As a matter of fact, I did carefully experiment before I ascertained the fact, and when I had constructed trans- [fol. 3574] mitting and receiving instruments, having the above named characteristics, I found that the distance to which messages could be intelligibly transmitted was very greatly enhanced, and the distinctness of messages received over shorter distances greatly improved.

G. Marconi.

Subscribed and sworn to before me this 5th day of April, 1902. James J. Cosgrove, Notary Public, New York County. (Notarial Seal.)

[fol. 3575] 2—260

Div. —, Room 91

Paper No. —

Address only "The Commissioner of Patents, Washington, D. C.," and not any official by name.

All communications respecting this application should give the serial number, date of filing, title of invention, and name of the applicant.

Department of the Interior, United States Patent Office

Washington, D. C., June 3, 1902.
Mailed " " "

Guglielmo Marconi, Care, Betts, Betts, Sheffield & Betts, 120 Broadway, New York, N. Y.

Please find below a communication from the Examiner in charge of your application Ser. No. 36,010, for Apparatus for Wireless Telegraphy, filed Nov. 10, 1900.

F. I. Allen, [Thomas Ewing],* Commissioner of Patents.

This action is in response to the communication filed May 1, 1902.

Applicant should either complete his response to the requirement of the second paragraph of page 2 of the last office letter or give a satisfactory reason for refusing to do so. It is noted that he has cancelled only the description of induction coils 6 and 7.

Applicant should also complete his response to the requirement of the last paragraph of page 3 of the last office letter or give satisfactory reason for his refusal. In this connection present claims 9, 10, 11, 12, 14 and 16 are open to the same objection.

Claims 11 and 12 are alternative in form for the reason given in the last office letter, paragraph 1, page 4, in connection with the then claim 10, now claim 12, namely that they are capable of covering both receiver and transmitter.

Claim 15 which includes any imperfect conducting device and its accessories, is allowed.

[*Words and figures enclosed in brackets erased in copy.]

All the other claims are rejected on Tesla, 649,621, May 15, 1900, division of 645,576, Mch. 20, 1900, filed Sep. 2, 1897. On page 3, lines 113 to 125, the details of device G are given. This is an electrical oscillator comprising an [fol. 3576] alternating current generator charging a condenser and an interrupter, which is a spark gap, for discharging the same. The primary of a transformer [condenser]* is fed by this oscillation producing circuit. The secondary is connected to the ground at one end and to an elevated conductor at the other. The periods of the primary and secondary circuits are in accord with each other.

Exr.

Claims 4, 13, 14 and 16, which specify a variable inductance and means for adjusting the inductance, are not patentable over Tesla because Lodge, of record, has shown that it is old to adjust the period of a circuit by a variable inductance; and claims 3 and 5, which specify an adjustable condenser, are not patentable over Tesla because applicant has shown in his prior patent No. 627,650 that this adjustment may be produced by a variable condenser. Since it is impossible to exactly calculate the values of the electro magnetic constants of two circuits for the purpose of making their time periods agree, it is fair to assume that the electrical oscillator of Tesla must necessarily be made with an adjustable inductance or condenser, or both.

G. C. Dean, Examiner, Div. 16.

G. K. W.

[fol. 3578] Serial No. 36010

Paper No. 9

Petition to Revive Am'dt. D

Filed Oct. 12, 1903

Amend. D

Docket Clerk, Oct. 12, 1903. U. S. Patent Office

United States Patent Office

Room 91

In the Matter of the Application of GUGLIELMO MARCONI, for Patent for Apparatus for Wireless Telegraphy: Serial No. 36010; filed November 10, 1900

Petition to the Commissioner

New York, October 6, 1903.

To the Commissioner of Patents, Washington, D. C.

SIR:

Your petitioners aver:

First: That they are the Attorneys for the applicant above named.

Second: That said Application was filed on or about November 10, 1900.

Third: That your petitioners were informed, by Office letter bearing date the 3rd day of June, 1902, that (1) Claims 1, 2, 3, 4, 5, 6, 7, 8, 13, and 16, were met by certain references which were given; (2) that Claims 9, 10, 11 and 12 were directed to matter apparently novel; and (3) that Claim 15 was allowable.

[fol. 3579] Fourth: That the said Application is owned by Marconi's Wireless Telegraph Company, Limited, by virtue of an Assignment recorded in the United States Patent Office, on November 10, 1900, in Liber B^{82}, page 210, Transfers of Patents.

Fifth: That the points raised by the Examiner in the said letter of June 3rd 1902, were extremely technical, and it

was necessary to refer said letter to Mr. Marconi, who has had the greatest experience with those problems which deal with the prevention of interference in the receipt of messages by electrical waves or oscillations. That, at the time of the receipt of said letter of June 3rd, 1902, Mr. Marconi was not in the United States, nor did he come to America until the latter part of December, 1902, when he was in Canada, actively engaged in establishing wireless telegraphic communication between the station at Glace Bay, and the station at Poldhu, in Cornwall, and in response to a cablegram from Glace Bay, at Mr. Marconi's request, your petitioners, early in January, 1903, sent him a complete set of the papers, in connection with the Application, serial No. 36,040, including the Office letter of June 3rd, 1902. That Mr. Marconi did not arrive in the United States until about January 27th, when he was here for a very short time, in connection with the establishment of telegraphic communication, by electric waves or oscillations, between the American station at Cape Cod, and the station in Poldhu, [fol. 3580] to which task Mr. Marconi was required to give his attention almost exclusively while in America, and which he successfully accomplished; that while he was in New York City, during his visit to America aforesaid, Mr. Marconi's attention was again called, on January 27, 1903, to the matter of the Patent Office action of June 3rd, 1902, in connection with this Application No. 36040, and while he then gave some information in reply, to said letter, he found that it was absolutely necessary to postpone the filing of a complete reply to the said Patent Office letter until he could very carefully examine his records, etc., then stored in England. These records being for this reason entirely inaccessible to Mr. Marconi, delay in amending was unavoidable.

Urgent business calls in connection with installing and perfecting his system of wireless telegraphy in Europe, required Mr. Marconi to leave this country on January 31st, 1903, and he has found himself quite unable, owing to pressure of business, and to illness, to return to this country until the present time, and he has also found the demands upon his time to be so great in connection with the various stations embodying his inventions throughout the different parts of Europe, as to prevent his giving full attention to the points raised by the Examiner in said letter of June 3rd 1902, and to prepare the papers and other memoranda

necessary to point out, in detail, the differences existing between his system of wireless telegraphy, and the systems [fol. 3581] and parts of systems of the references cited against his Claims. That after Mr. Marconi's departure to Europe your petitioners wrote to Mr. Marconi, and also to Marconi's Wireless Telegraph Company, Limited, at London, England, asking them to send the required information to this country, namely on January 27th, 1903, and March 20th, 1903. That thereafter, on April 4th, 1903, your Petitioners received from said company a letter to the effect that Mr. Marconi had informed the Company that the papers referred to in our letter of January 27th to him had been dispatched. That the said papers were never received. That not having received the necessary information, your petitioners again addressed a letter to Marconi's Wireless Telegraph Company, Limited, dated May 13th, 1903, urging that the papers above referred to be furnished, and in response to a fourth letter, dated June 5th, 1903, your petitioners were in receipt of a cablegram dated July 3rd, 1903, stating that Mr. Marconi has been ill, but that it is hoped to send the papers on July 20th.

That on August 21, 1903, certain papers were received, but no remarks from Mr. Marconi.

That Mr. Marconi was in New York from September 28th, 1903, to October 3rd, 1903, and then was information from him available.

Fifth: That until the receipt of the papers and the information referred to, your petitioners were unable to file a complete and full response to the Examiner's letter of June 3rd, 1902.

[fol. 3582] That thereafter your petitioners have carefully considered the questions involved, and have prepared and amendment and argument which covers fifteen full-sized typewritten pages, and is completely responsive to the last Office action, and is annexed hereto.

Wherefore your petitioners request that the said Application, serial No. 36010, be revived as a pending Application, and that the Examiner in charge thereof be instructed to reopen the same and enter the amendment hereto annexed.

Respectfully, Betts, Betts, Sheffield & Betts.

While it is believed the foregoing petition and the appended affidavit are sufficient of themselves to warrant the

revival of this application, attention is respectfully directed to the fact that applicant's British patent No. 7777 of 1900 will absolutely preclude the assignees of this valuable invention from filing a new application.

Respectfully, Thos. E. Robertson, Assoc. Attorney.

[fol. 3583] City, County and Southern District of New York, ss:

Louis Frederick Holbrook Betts being duly sworn, deposes and says: I am a member of the firm of Betts, Betts, Sheffield and Betts, Attorneys for Guglielmo Marconi, in the matter of the above entitled Application.

Referring to the papers filed in connection with said Application, it will be seen that the last action of the Patent Office, dated June 3rd, 1902, raised certain questions extremely technical, and which required to be referred to a person technically and practically skilled in the art of wireless telegraph, by the employment of Hertzian waves, or electrical oscillations, which is an entirely novel art, of which little is known as to the practical realization, and the theory of which is still unsettled, and more especially was it necessary to refer to such a skilled person, the question of the likeness of the systems of Lodge and of Tesla, when used separately, or when employed together, and it therefore became absolutely necessary, in order to file a complete response to the Examiner's letter, to refer these matters to Mr. Marconi, who has had the greatest experience with the delicate problems of wireless telegraphy, and who has succeeded in solving many of these problems only after the most painstaking efforts, and after having devised many new forms of apparatus and combinations of apparatus. [fol. 3584] Inasmuch as the Application, No. 36010 especially deals with the problem of preventing interference in the receipt of messages by electrical waves or oscillations, to which question Mr. Marconi has given the most careful and practical study, it was decided to await his arrival in this country before submitting the questions raised by the Examiner's letter to him.

Mr. Marconi did not come to the United States, after the receipt of the Patent Office letter of June 3rd, 1902, until the end of January, 1903, on which occasion his time and atten-

tion were almost exclusively devoted to the establishment of electrical communication between the American station at Cape Cod, and the station at Poldhu, in Cornwall, and to the development of his new receiver, which employs a varying magnetic field for assisting the receipt of electrical oscillations. When Mr. Marconi was in New York, and at all available in connection with his Application No. 36010, the Examiner's letter of June 3rd, 1902, was submitted to him, in connection with the other papers relating to said Application, and was very carefully considered, but Mr. Marconi found himself unable to completely reply to said letter until he could examine his records and data, then stored at London. Inasmuch as he was then called to England, in connection with the operation and protection of his stations in European countries, he requested that he be informed by your petitioners, as to the papers and information necessary to be furnished, in connection with said Application, [fol. 3585] No. 36010, and this was done on January 27th, and later on on March 20th, our firm wrote to Mr. Marconi, and to the Marconi's Wireless Telegraph Company, Limited urging that the information referred to, together with the papers, be sent as soon as possible, and in reply our firm received a letter, on April 11th, 1903, to the effect that Mr. Marconi had informed the Company that the affidavits referred to in our letter of January 27th had been dispatched by the Notary. These affidavits were never received. After waiting a reasonable time for the receipt of these papers which were deemed necessary in connection with the Application No. 36010, we again wrote to the Marconi's Wireless Telegraph Company, Limited, on May 13th, 1903, urging that these papers should be furnished to us, and, in response to a fourth letter, dated June 5th, 1903, we were in receipt of a cablegram, dated July 3rd, 1903, that Mr. Marconi has been ill, and this is the reason why the papers were not sent in response to our last letters.

That thereafter, on August 21st, 1903, we received certain papers, but no remarks from Mr. Marconi. That thereafter, Mr. Marconi was in New York from September 28th to October 3rd, 1903, and then was information from him available. That we thereafter prepared an amendment and argument in reply to the last office action upon the application in question, which amendment, with the argument relating thereto, covers fifteen large typewritten

[fol. 3586] pages, and is completely responsive to the last office action.

It is evident, therefore, that the filing of an amendment in response to the official action of June 3rd, 1902 has been prevented by circumstances beyond the control of the inventor, the owners of the patent, and the attorneys for applicant.

L. F. H. Betts.

Sworn to and subscribed before me this 6th day of October, 1903. Francis White Proscher, Notary Public, Queens Co. Cert. filed in New York County. (Notarial Seal.)

[fol. 3587] United States Patent Office

Room 91

In the Matter of the Application of Guglielmo Marconi, for Patent for Apparatus for Wireless Telegraphy, Serial No. 36,010, filed November 10, 1900

[Amend. D.]

New York, October 6, 1903.

Hon. Commissioner of Patents,
Washington, D. C.

Sir:

Replying to Office action of June 3, 1902, we authorize and request the following amendments of the substituted Specification and Claims:

Cancelled per E

Specification, page 3, line 10, after "station", add "Fig. 9 is a view, similar to Fig. 2, showing the employment of a condenser in the earth connection of the receiving apparatus".

Page 5, after "communicating-system", last line of said page, please add: "A condenser, X (Fig. 9) may be inserted in the open circuit of the receiving-station, between the coil f' and the capacity E".

Page 6, after line 23, please insert the following:

"If preferred, the oscillation-radiating conductor and the oscillation-receiving conductor, or either, may be connected [fol. 3588] to any suitable capacity instead of being directly earthed. On certain rocky islands, it has been found impossible to make what telegraph engineers call a good earth or ground connection, but the apparatus has worked well in such places when, instead of a ground connection, a large metallic surface (plates of zinc, of about 400 square feet surface, were found useful) placed on the surface of the rocks, has been utilized."

[Matter enclosed between rules erased in copy.]

Cancel the amendment dated July 5, 1901, also the correction thereof contained in our Amendment dated December 6, 1901, and substitute the following:

D[1] "Various forms of transformers, etc., which may be employed by me are described in my British Patent No. 7,777 of 1900."

Page 10, cancel the description of details of tune No. 7, in the tables relative to the Transmitting-station.

Page 11, cancel the description of details of tunes 7, 8 and 9, in the tables relative to the Receiving station.

Cancel Claims 1, 2, 3, 4, 5, 6, 7 and 8, and substitute the following:

D[2] "1. At a station employed in a wireless telegraph system, a signalling-instrument comprising an induction-coil, the secondary circuit of which includes a [fol. 3589] condenser discharging through a means which automatically causes oscillations of the desired frequency; an open circuit electrically connected with the oscillation-producer aforesaid and a variable inductance included in the open circuit, substantially as and for the purpose described.

"2. At a station employed in a wireless telegraph system, an oscillation-receiving conductor, a variable inductance connected with said conductor; a wave responsive device electrically connected with said

conductor and in circuit with a condenser, substantially as and for the purpose described.

D² "3. At a station employed in a wireless telegraph system, a signalling instrument comprising an induction coil, the secondary circuit of which includes a condenser discharging through a means which automatically causes oscillations of the desired frequency, and the primary circuit of which includes a generator; means for varying the primary circuit; an open circuit electrically connected with the oscillation-producer aforesaid, and a variable inductance included in the open circuit, substantially as and for the purpose described.

Substitute F⁵

"4. At a transmitting-station employed in a wireless telegraph system, the combination of a transformer whose secondary is connected to an open circuit including a radiating conductor at one end and capacity at the other end, and whose primary is connected to a condenser-circuit discharging through [fol. 3590] a means which automatically causes oscillations of circuit and the open circuit being in electrical resonance with each other, substantially as described.

D² "5. At a transmitting-station employed in a wireless telegraph system, the combination of a transformer whose secondary is connected to an open circuit including a radiating conductor at one end and capacity at the other end, and whose primary is connected to a condenser-circuit discharging through a means which automatically causes oscillations of the desired frequency, such condenser-circuit and the open circuit being in electrical resonance with one another; an induction-coil, the secondary winding of which includes the condenser aforesaid, a source of energy included in the primary winding of said coil, and means for varying the circuit of said primary winding, substantially as described.

[Matter enclosed between rules erased in copy.]

"6. At a transmitting-station employed in a wireless telegraph system, the combination of a trans-

former whose secondary is connected to an open circuit including a radiating conductor at one end and capacity at the other end, and whose primary is connected to a condenser-circuit discharging through a means which automatically causes oscillations of the desired frequency, and means for adjusting the oscillation period of each of the two circuits connected with the transformer to bring them into accord with each other, substantially as described.

Substitute F[6]

"7. At a transmitting-station employed in a wireless telegraph system, the combination of a trans- [fol. 3591] former whose secondary is connected to an open circuit including a radiating conductor at one end and capacity at the other end, and whose primary is connected in series with an adjustable condenser, and a means which automatically causes oscillations of the desired frequency, substantially as described.

[Matter enclosed between rules erased in copy.]

D[2] "8. At a transmitting-station employed in a wireless telegraph system, the combination of a transformer whose secondary is connected to an open circuit including a radiating conductor at one end and capacity at the other end, a variable inductance being included in said circuit [said circuit]* and whose primary is connected to a condenser-circuit discharging through a means which automatically causes oscillations of the desired frequency, substantially as described.

"9. At a transmitting-station employed in a wireless telegraph system, the combination of a transformer whose secondary is connected to an open circuit including a radiating conductor at one end and capacity at the other end, a variable inductance being included in said circuit, and whose primary is connected in series with an adjustable condenser and with a means which automatically causes oscilla-

---

"21. The method of communicating intelligible signals by tuned electrical oscillations, consisting in adjusting the electrical resonance in the oscillation-producing circuit, at a transmitting-station of a wireless telegraph system, so as to accord with the electrical resonance of the radiating-circuit at said station, substantially as described.

"22. The method of communicating intelligible signals by tuned electrical oscillations, consisting in adjusting the time periods of such oscillations in the oscillation-producing circuit and in the radiating-circuit, at a transmitting-station of a wireless telegraph apparatus, so as to be the same or harmonics of each other, substantially as described."

[fol. 3596] Argument

The formal objections of the Office are met by the changes in the Specification.

Cancelled E

[A new figure (Fig. 9) has been added to the drawings.]*

---

* [Words enclosed in brackets erased in copy.]

The Claims as now drawn differentiate the present invention from that of Tesla, especially in respect to the apparatus for automatically producing electrical oscillations of desired frequency. In the Tesla Patents cited by the Examiner, the oscillation-producing connections and devices are vaguely described, but are not illustrated. Apparently, they comprise a transformer whose primary was discharged through a condenser and through a *mechanically-operated* break.

Mr. Marconi, on the other hand, discharges the primary throught the condenser circuit and through a sparkgap which *automatically* produces oscillations of desired frequency.

Tesla does not show or describe any means for adjusting the resonance of the two transformer circuits at the transmitting stations.

The apparatus described in the cited Tesla Patents can have no value as references, since they are not workable in wireless telegraphy, and will not work over even 1 100 part of the distance to which oscillations can be sent by Marconi apparatus of the same dimensions.

[fol. 3597] The object apparently aimed at by Tesla, in the cited Patents, is to transmit electrical currents of high potential by conduction through the high and rarified stratum of air, and he states, clearly (in Patent No. 649,621, lines 73, etc., page 2) "that the phenomenon here involved is one of true conduction and not to be confounded with the phenomena of electrical radiation".

Mr. Marconi's apparatus is one for propagating and utilizing radiant energy, and his system of wireless telegraphy depends upon the detection, at a distant station, of these radiated waves, in such a way as to vary the local circuit of apparatus at such station.

Mr. Tesla's apparatus is one for propagating electrical oscillations at the station, conducting them (by the air) to a distance station, and utilizing the same for light, heat or power, independent of local generators. For this, he requires (page 5, patent 645,576) that the terminals at each station shall be elevated so as to maintain a "moderate" height of 35,000 feet above sea level.

Mr. Marconi has sent oscillations more than three thousand miles, using terminals of only 250 feet.

The arrangement of apparatus figured and described in Tesla's U. S. Patent No. 645,576, dated March 20, 1900, is radically different in function from that shown in Marconi's U. S. Application Serial No. 36010.

In the above mentioned patent, Tesla describes in detail an oscillation transformer the secondary circuit of which [fol. 3598] consists of a flat helical coil of wire generally of considerable length; in some cases he says it would be 50 *miles* in length. The primary circuit was to consist of a few turns concentric with the secondary circuit. He furthermore states that the primary circuit is to be traversed by the discharges of a condenser and the secondary circuit then becomes a seat of high frequency high pressure electromotive forces. It is important to notice that in the specification of Tesla No. 645,576 and in other correlated specifications by Tesla, not one word is said about the application of this oscillation transformer to the production of *electric waves*. Tesla's idea clearly is that he can transmit electric energy through rarefied air; for example, through the upper strata of the atmosphere, if he can introduce into one part of this rarefied air high frequency electric currents, and as he says *conduct* electricity from one place to the other. He proposes to place at two localities oscillation transformers of the kind described to connect one end of each secondary circuit to the earth and the other end to an aerial of insulated wire. At the transmitting end he proposes to set up oscillations of high frequency and high electromotive force, and at the receiving end to draw off in some way not explained in detail the alternating current which has been transmitted through the rarefied atmosphere from the transmitter.

Now this process has no resemblance whatever to the process which is conducted by Marconi's apparatus. In this latter case the transmitter is definitely arranged with the object of throwing off from the radiating wire elec- [fol. 3599] tric or Hertzian waves. Tesla's object is to inject into the upper atmosphere high frequency electric currents and to *conduct* them by means of the rarefied air to the distant place. Tesla never mentions in his specifications the words Hertzian waves or electric waves; his invention is concerned with a totally different process, and his appliances are unsuited for Hertzian wave generation.

Tesla does not mention as important that the primary and secondary circuits of his oscillator should be so ad-

justed as regards inductances and capacity that the product of the two for each circuit is the same. It is true he says the results are "particularly satisfactory" when the primary Coil A^1 with its secondary Coil C^1 at the receiving end is adjusted to vibrate in synchronism with the transmitting Coil A C. (See lines 40-45, page 4, No. 645,576). But this rough statement does not supply the information which Marconi gives.

Again, Marconi describes in great detail the particular shapes and sizes of the oscillation transformers at the transmitting and receiving ends and the other details as to the capacities which are alone effective in enabling him to construct an apparatus for Syntonic Hertzian Wave Telegraphy.

Tesla is not even original in the form of his oscillator. The flat spiral coils which he uses are merely a reproduction of Knockenhauer's spirals figured in nearly every text book on Physics.

Hence we can say as follows:

[fol. 3600] (i) Tesla has never applied his oscillator to the special production of Hertzian waves, but always for the production of high frequency electric currents which he proposes to *conduct* through the air.

(ii) Tesla's flat coil oscillator is not suitable for the production of Hertzian waves, and especially unsuitable for their absorption and reception.

(iii) He gives no explicit instruction for the tuning of all four circuits of the transmitting and receiving oscillation transformers.

On the other hand Marconi sets out:

(i) With the definite idea of producing a practical syntonic Hertzian Wave telegraphy, and this he has practically achieved. He does not operate by means of *Conduction* through rarefied air, but by means of Hertzian Waves produced in the ether.

(ii) He gives explicit details of the oscillation transformers which are quite different in form from Tesla's, and also defines the rules by which Syntonism is secured, by adjusting the capacity and inductance of four different circuits.

Tesla's apparatus taken as a whole is not the equivalent of Marconi's. It could not perform the same duty and if set up exactly as Tesla describes, Syntonic Hertzian Wave telegraphy could not be conducted by it. Hence if it is not equivalent, it is not anticipatory.

The so-called Tesla oscillator is an air core induction [fol. 3601] coil devised for a particular purpose by Tesla. The Marconi oscillation transformer is a quite different form of induction coil devised for transforming oscillations of Hertzian Wave frequency.

There is, therefore, no use of a Tesla Oscillator by Marconi, but only a use of scientific principles, some of which are applied by Tesla for one purpose and some by Marconi for another.

The notion that any sort of transformer with two coils on it, in fact, any air-core transformer can take the place of Marconi's special coils, is quite a fallacy.

An allowance of the Claims is now requested.

Respectfully submitted, Betts, Betts, Sheffield & Betts, Attorneys for Marconi.

Patent Office, Oct. 12, 1903. Div. 16. Filed

In the Matter of the Application of GUGLIELMO MARCONI, for Patent for Apparatus for Wireless Telegraphy; Serial No. 36,010; Filed November 10, 1900

New York, October 6th, 1903.

Hon. Commissioner Patents, Washington, D. C.

SIR:

Please recognize, Thomas E. Robertson, of 605 Seventh Street, Washington, D. C., as our Associate Attorney, in the matter of the above-entitled Application.

Yours respectfully, Betts, Betts, Sheffield & Betts, Attorneys for Marconi.

[fol. 3603] Paper No. 10

U. S. Patent Office, Oct. 15, 1903

Mailed

Department of the Interior, United States Patent Office

Washington, D. C., October 15, 1903.

In the matter of the application of GUGLIELMO MARCONI, for patent for Apparatus for Wireless Telegraphy, filed November 10, 1900, Ser. No. 36,010

Examiner's Statement

This is a petition to revive the above entitled application which became abandoned June 3, 1903, by reason of failure to prosecute the same within one year from the date of the last official action, which was June 3, 1902.

Annexed to the petition is an affidavit by one of the attorneys substantiating the statement of facts alleged by the petition to constitute a showing of unavoidable delay.

These facts are that because of the technical nature of the invention it was necessary to submit the questions raised by the last office letter to Marconi, who was not in the country when the letter of June 3, 1902, was received, and who did not arrive here until the latter part of December, 1902.

No attempt has been made to account for the seven months delay intervening between the receipt of the last office letter and Marconi's arrival in this country. In this connection attention is called to ex parte McElroy, 101 O. G. 2823, in which it was decided that the *delay* must be [fol. 3604] unavoidable and not merely that a *certain portion of the delay* must be unavoidable.

Early in Janaury, 1903, Marconi, who was then at Glace Bay, cabled the attorneys for the record of the application, which was sent to him. Marconi was too busy evidently to attend to the matter until his arrival in the United States on January 27, 1903, at which time he gave the attorneys partial information, but found it necessary to postpone filing a complete reply to the last office letter until he could examine his records in England.

The necessity for consulting these records was apparently caused by the citation of two patents to Tesla, which in the

opinion of the Examiner discloses the invention presented in this application. These patents show in the drawings purely diagrammatic and conventional representations of certain apparatus known for many years as the "Tesla oscillator". Apparently Marconi did not make any serious attempt to find out what these patents really did disclose because he has amended his claims in such a way that they are still readable upon the Tesla patents. This will be hereinafter more fully explained.

Marconi left this country on January 31, 1903, and owing to pressure of business found himself unable to prepare the necessary instruction to his attorneys.

On March 20, 1903, nine and one-half months after the date of the last letter, the attorneys called on the Marconi Company for the necessary information.

On April 4, 1903, ten months after the date of said office letter, the attorneys received a communication from the Company stating that Marconi said he had already sent the papers required. These papers were never received.

On May 13, 1903, eleven months after the date of said [fol. 3665] office letter, the attorneys addressed a letter, which should certainly have been a cablegram, to the Marconi Company urging that the papers be sent and on June 5, 1903, twelve months after the date of said office letter, another such request was sent to said Company.

It would seem that some action based on the partial information obtained from Marconi January 27, 1903, might have been submitted by the attorneys between May 13 and June 3, 1903, that would have saved the case from abandonment.

On July 3, 1903, thirteen months after said office letter, a cablegram was received by the attorneys stating that Marconi had been ill, but hoped to send the papers July 20, 1903.

On August 21, 1903, fourteen and one-half months after the date of said office letter, the desired papers were received, but were accompanied by no remarks from Marconi.

On October 3, 1903, sixteen months after said office letter, Marconi was in New York and then information was received from him.

This petition was then presented on October 13, 1903, sixteen months and ten days after the date of the last office letter and was accompanied by a fifteen page amendment alleged to be completely responsive to the last office action and presumably based on the information imparted by

Marconi to his attorneys. This amendment will be hereinafter more fully described.

Although Marconi alleges that he was so busy with business matters requiring his entire attention, that he was unable to give any of his time to the prosecution of this application, he has nevertheless found time to file four applications for letters patent in this office, namely, 132,974, [fol. 3606] November 28, 1902; 141,398 and 141,399, February 2, 1903; and 172,617, September 10, 1903.

It is by no means unusual that an active inventor is too busy perfecting his inventions and filing applications for later improvements, to devote much of his time to the prosecution of his applications already filed, but such a condition of affairs, it is thought, does not constitute the unavoidable delay mentioned by statute as prerequisite to the revival of an abandoned application.

At this point reference is made to applicant's co-pending application serial number 82,856, filed November 19, 1901. In answer to the rejection of June 21, 1902, the attorneys found it possible to prepare and submit an elaborate amendment although the invention involved matters of technical difficulty of much the same order as those involved in this application.

On October 7, 1903, in said application an affidavit was submitted by Prof. J. A. Fleming, the retained expert of the Marconi Company, explaining certain theoretical matters on which additional information is asked by a previous office letter.

It would seem that the services of this expert were just as available to the Marconi Company in this application as they were in application serial number 82,856 although no attempt apparently was made to call them into requisition when it was found that Marconi was not available.

In view of the foregoing it is thought that the affidavit of the attorneys fall far short of the showing of unavoidable delay covering the entire period contemplated by R. S. 4894 and by Rule 172 as construed by the Commissioner of Patents in the following cases:

[fol. 3607] Ex parte Klenha, 28 O. G., 1272.
Ex parte Pratt, 39 O. G., 1349.
Ex parte Murray, 56 O. G., 1060.
Ex parte McPhil, 56 O. G., 1060.
Ex parte Raeymaekus, 60 O. G., 1749.
Ex parte Heine, 64 O. G., 1006.

It has been the Examiner's practice, however, to overlook much in showings of delay in similar cases where the amendment submitted with the petition has been such as to put an application in condition for allowance without further action on the part of the office and in such cases his favorable recommendations have heretofore been accepted by the Commissioner.

In order to ascertain if such treatment could be accorded in the present case a careful examination has been made of the amendment submitted with this petition. As a result of such examination the following report is made:

Many of the claims are not patentable over Tesla, 645,576, and 649,621, of record, the amendment designed to overcome said reference as well as Marconi's pretended ignorance of the nature of a "Tesla oscillator" being little short of absurd. Ever since Tesla's famous lecture on alternating currents of high frequency delivered before the American Institute of Electrical Engineers in 1891, and repeated in 1892 before the Institute of Electrical Engineers and the Royal Institution, London, the Societe Internationale des Electriciens and the Societe Francaise de Physique, Paris, which lectures have been widely published in all languages, —the term "Tesla oscillator" has become a household word on both continents.

Anyone who has read such elementary text books on physics as are used in the ordinary high school or in the first [fol. 3608] year of a technical college course knows what this term means. Marconi evidently knew in 1897, because he is quoted by Della Riccia in the Rivista di Artiglieria e Genio, Vol. 2, 1898, page 343, as having said that he employed such oscillator and also an Elihu Thomson oscillator in certain early experiments at Dover, but that the results were not so good as those obtained by using an ordinary induction coil.

The Tesla oscillator as a means for generating currents of high frequency and high tension for use in wireless telegraphy was first patented by Dr. Braun (see British patent 1862 of 1899, published January 27, 1900, or Swiss patent, 18577, published November 30, 1899, or German patent, 111,578, filed October 14, 1898).

Braun did not tune the transmitting wire to the period of the oscillator but this is clearly described in the Tesla patents of record (see page 4, 645,576 and the last three lines

of page 1 down to the first ten lines of page 2 of 649,621, see also claims 5, 7, 9 and 10.)

On page 4, of 645,576 it is said that "the primary and secondary circuits in the transmitting apparatus being carefully synchronized, * * *". The term "synchronized" as applied to two circuits is synonymous with the term "tuned". In 649,621 at the point above indicated and elsewhere it is clearly stated that the elevated conductor is so designed and adjusted that the point of maximum potential is coincidental with the end of the wire, that is, the transmitting wire is equal to a quarter wave length of the disturbance in the circuit and consequently of the radiated wave.

This means nothing more nor less than tuning the elevated conductor to the Tesla oscillator, (which is any closed circuit containing a spark-gap, a condenser and an inductance,) inductively associated with said vertical wire. Au-
[fol. 3609] thority for this statement may be found in three papers dealing with the theoretical aspects of electrical oscillations and electro magnetic waves, namely:

Ascoli in "Electricista", Rome, August 1897.

Slaby in "Electrician", London, April 25 and May 2, 1902.

Fessenden in "Transactions Amer. Inst. Elec. Engr." December, 1899.

Tuning a closed persistently oscillating circuit with the vertical transmitting wire as well as the advantages resulting therefrom has been described by Pupin in the paper presented before the American Institute, December, 1899, and by Fessenden in patents 706,735 and 706,736, August 12, 1902, where the closed persistently oscillating circuit is *conductively* connected with the open oscillator or good radiator i. e., the transmitting wire, and the same thing has been disclosed by Stone in patents Nos. 714,756 and 714,831, wherein the closed and open circuits are *inductively* connected.

The amendment does, indeed, cancel much of the new matter that has been injected into this case since it was filed but on the other hand more new matter is sought to be added by said amendment. Specifically the amendment to page 5 after the last line thereof specifying that a condenser X may be inserted in the open circuit between the coil j' and the earth E is not justified by the original dis-

closure and is, in fact, an idea borrowed from Stone's patent 737,179, August 25, 1903,—see Fig. 2.

The new figure illustrating this construction is without justification.

The amendment to page 6, line 23, referring to the use of the "artificial ground" is new matter and is an idea taken from Fessenden's patent 706,746, August 12, 1902.

[fol. 3610] These features have not been claimed and thus according to the settled practice the amendment would not have been entered if presented during the regular prosecution of the case because an amendment cannot be entered in part, (ex parte Stern, 59 MS. Dec. 254).

The proposed amendment presents a number of apparatus claims and two method claims (claims 21 and 22). Therefore this amendment, if presented during the regular prosecution of the case, would have resulted in an immediate requirement of division and, as decided in ex parte Tichirner, 97 O. G., 187, the business of the office would in such case be best facilitated by refusing to enter the amendment.

As decided in ex parte Morrison 99 O. G., 2969, such an amendment would not have been entered even if presented when the case was alive on the last day of the year allowed by law for the prosecution of the case, in order to save it from abandonment.

It is thus apparent that the amendment accompanying this petition is not even of such character that it may be entered, much less put the case in condition for allowance, and that therefore there is not the same reason for overlooking the deficiencies of the showing made to account for the delay that might exist were the amendment one which would put this case in condition for allowance.

The associate attorney has presented a brief argument to the effect that failure to revive this case will work irreparable injury to the assignees because Marconi's British patent No. 7777 of 1900 filed April 26, 1900, operates as a bar to a new application for what he calls "this valuable invention".

It is true that said British patent as well as other foreign patents so operates and it is true that this is a valuable [fol. 3611] invention, but, in the opinion of the Examiner, the references above cited and also numerous other references, some of which are hereinafter set forth, effectually dispose of the idea that this is a valuable *application*, however valuable may be the invention disclosed therein, be-

cause any patentable claims which this application will support in view of the state of the art must necessarily be of the most limited character.

Some of these references, above referrred to, which disclose a closed persistently oscillating circuit known as the D'Arsonval or the Oudin oscillator (a modification of the Tesla oscillator) inductively associated with an open or radiating circuit attuned thereto for the purpose of transmitting electro magnetic signal waves, are

Paper No. 11

Supplemental Petition and Proposed Amendment A E
Filed Oct. 24, 1903

Amend E

United States Patent Office

Room 91

In the Matter of the Application of Guglielmo Marconi for Patent for Apparatus for Wireless Telegraphy Serial No. 36,010. Filed November 10, 1900.

Before the Commissioner of Patents by Petition

City and County of New York,
Borough of Manhattan, ss:

Louis Frederic Holbrook Betts, being duly sworn, deposes and says:

I am the Louis Frederic Holbrook Betts who has heretofore made an affidavit in this matter, verified October 6, 1903, and I have read the recommendation of the Examiner that the petition to revive the above entitled application be denied.

In the first place, I desire to point out that the Examiner is in error in stating that Mr. Marconi "did not arrive here until the latter part of December, 1902", if by "here" the Examiner means the United States. It is distinctly pointed out in the petition, and in my affidavit, that Mr. Marconi arrived in Canada in December, 1902, but did not arrive in New York until the 27th day of January, 1903. Therefore it was not possible to confer with Mr. Marconi until the 27th of January, 1903, on which very day we did promptly bring this matter to his attention.

The Examiner then states that, "No attempt has been [fol. 3613] made to account for the seven months' delay intervening between the receipt of the last Office letter and Marconi's arrival in this country."

And the Examiner calls attention to *Ex Parte McElroy*, 101, O. G., 2823.

Deponent does not believe that this case is applicable to the present case, because in the McElroy case it appeared

that it had been "the practice" of the applicant to postpone the amending of his applications until the last few weeks before the time limit expired, and that when in this instance he was about to amend his application he was stricken with typhoid fever, and therefore could not do so, and *by reason of this practice* the Commissioner held that the first eleven months delay was "intentional," and therefore that the delay was unavoidable because only a "certain portion of the delay" had been explained away.

This "*practi*" of waiting eleven months before making an amendment has not been adopted or followed by this applicant, as I will now point out.

The application was filed November 7th, 1900. It was rejected December 24th. It was amended July 1, 1901. It was again rejected August 12, 1901. Again it was amended on December 6, 1901. Amended April 28, 1902, and again rejected on June 3, 1902.

The last amendment was filed six weeks after rejection.

Considering the fact that the applicant resides more than [fol. 3614] 3000 miles away from his attorneys, it necessitates consultation with him by letters back and forth, often several letters to prepare a single amendment.

If, however, it is thought that it is necessary to explain the reason for not acting on this case between the 3rd day of June, 1902, and the 27th day of January, 1903, deponent, upon information and belief, states as follows; basing his information upon communication, from the Marconi Company, and upon statements in the public prints as to the movements of Mr. Marconi.

Mr. Marconi was not, unless for very brief periods of time, in a position to take up the amendment of his application and could not be visited by his attorneys.

In the early part of July, 1902, Mr. Marconi was called to Italy to make experiments in wireless telegraphy for the Italian Government upon the Italian war-ship "Carlo Alberto," which had been furnished to him by the Italian Government for this purpose. He left London, as I am informed, very hurriedly for this purpose, sailing first to Gibraltar and afterwards to Spezzia.

During this time, he succeeded, as I was informed, in transmitting messages, by his wireless system, between England and Gibraltar, and subsequently successfully transmitted one or more wireless messages from England direct to Spezzia, in the gulf of Genoa. This latter achievement

was considered, at the time, a marvelous event, as it involved transmission across Europe. These experiments occupied, [fol. 3615] as I believe, a number of weeks, and after completing the same, he was invited by the Czar of Russia to come to Cronstadt, Russia, and was permitted by the Italian Government to go there upon the same war-ship, "Carlo Alberto." He accordingly sailed for Russia, and during this trip was successful in transmitting messages from England to Cronstadt. For this achievement, as I was informed, he was decorated at the time, by the Czar of Russia, with an Order.

We were informed that it was hoped that he would return to England in September, 1902, and that he would then proceed immediately to Cape Breton, Canada, but he was unable to do so. It was always, however, represented to us that he was coming to this country soon. He did not arrive, however, in Cape Breton, until December, 1902, and during all of the time from June to December was only temporarily in England, as we were informed. That Mr. Marconi came to this country as early as feasible is, we think, sufficiently indicated by the fact that he came on the "Carlo Alberto," which had been placed at his service for the purpose, and he was, naturally, anxious not to keep that ship longer than absolutely necessary, she being under orders to sail for Venezuela as soon as she could be spared from his experiments.

It thus appears that from June 3, 1902, until Mr. Marconi arrived in Canada, he was more than 3000 miles away from his attorneys, being for the most part of the time in the Mediterranean and Baltic Seas, conducting experiments on the above mentioned Italian war-ship, and therefore it is [fol. 3516] submitted to your Honor that the first part of the delay has been satisfactorily shown to have been unavoidable, as well as that of the last part of the whole period.

The Examiner states that "it would seem that some action, based on the partial information obtained from Marconi January 27, 1903, might have been submitted by the attorneys between May 13th and June 3, 1903, that would have saved the case from abandonment." We can hardly suppose that the Examiner recommends or approves of the practice of making a merely formal and insufficient reply to an Office letter, and one known to be insufficient at the time of making it, especially when, as in this case, detailed and accurate information on which to base what

was believed to be an adequate reply, was promised in a short time.

The only information which Mr. Marconi gave us on January 27, 1903, was a very brief verbal one, and as Mr. Marconi informed us that upon his return to England he would send us a full written report, after he had consulted with his documents there, we had no records to go by to formulate an amendment between May 13, 1903, and June 3, 1903, as suggested by the Examiner. The verbal information which Mr. Marconi did give us on January 27, 1903, was not sufficiently clear or well enough understood by us to have answered the last Office action.

It is submitted that Mr. Marconi's attorneys, in view of [fol. 3617] the facts above set forth, and in view of the facts set forth in my former affidavit, had every reason to expect that they would have received, long before the year's time elapsed, sufficient information from Mr. Marconi to amend the case in response to the last Office letter, and that the delay in the case arose from the exceptional circumstances of Mr. Marconi's absence from England, engaged in experiments in perfecting his wireless system, and the inevitable and unexpected delays in coming to this country, and in putting his attorneys in possession of his statements which grew out of those exceptional occupations.

L. F. H. BETTS.

Sworn to before me this 22nd day of October, 1903.

JAMES J. COSGROVE,

(NOTARIAL SEAL). *Notary Public,*
New York County.

[fol. 3618] UNITED STATES PATENT OFFICE.
Room 91.

In the matter of the Application of Guglielmo Marconi, for Patent for Apparatus for Wireless Telegraphy. Serial No. 36,010. Filed November 10th, 1900.

New York, October 24, 1903.

Hon. Commissioner of Patents, Washington, D. C.

SIR:

We transmit herewith a supplemental showing, duly verified, in the matter of the petition to revive the above entitled application.

In order to remove any portions of the amendment of October 6th, 1903, (filed with the original showing and petition) which may be considered objectionable on the ground that said amendment cannot be entered because, in the Examiner's opinion, it contains new matter and also contains method as well as apparatus claims, it is hereby requested that the following amendment may be made to the aforesaid amendment of October 6th, 1903.

Cancel the last eleven lines of page 1 of the amendment dated October 6th, 1903.

[fol. 3619] Cancel the first eight lines of page 2 of said amendment.

Cancel claims 21 and 22 on page 9 of said amendment.

Cancel the second paragraph on page 10 of said amendment, said paragraph reading as follows:

"A new Figure (Fig. 9) has been added to the drawings."

Respectfully submitted,

BETTS, BETTS, SHEFFIELD & BETTS,

Attorneys for Marconi.

[fol. 3620] Paper No. 12

U. S. Patent Office, Oct. 26, 1903, Mailed

Department of the Interior, United States Patent Office

Washington, D. C., October 26, 1903.

IN THE MATTER OF THE APPLICATION OF GUGLIELMO MARCONI, FOR PATENT FOR APPARATUS FOR WIRELESS TELEGRAPHY. FILED NOVEMBER 10, 1900. SER. NO. 36,010.

Before the Commissioner by Petition

Examiner's Statement

On October 12, 1903, a petition was filed to revive the above entitled application, which became abandoned June 3, 1903, under R. S. 4894; on October 15, 1903, the Examiner submitted an answer recommending that the petition be denied; and on October 24, 1903, an additional affidavit was filed in support of the petition of October 12th. In view of this affidavit the following answer is respectfully submitted.

The additional affidavit sets up an argument and a statement of alleged facts, based on the information and belief

of one of the attorneys, as to Marconi's movements between June 3, 1902, and the latter part of December, 1902, said facts, so alleged on information and belief, being intended to show that the delay existing between the aforesaid dates was an unavoidable delay.

The facts submitted in this additional affidavit, in the Examiner's opinion, merely serve to emphasize the position [fol. 3621] taken by him in his answer of October 15th, namely, that Marconi was unable to attend to his Patent Office business by reason of other business interests.

What Marconi's other business interests were is immaterial and the fact that he was successful in his business, as repeatedly emphasized by the attorney in both original and supplemental showings evidently for the purpose of strengthening his case, is irrelevant and incompetent.

It was held in ex parte Smith, 101 O. G., 1369, that the plea of "other business engagements" was not sufficient to account for the delay which resulted in the abandonment of an application under R. S. 4894.

In ex parte Beecher, 101 O. G., 1132, "unavoidable delay" was defined as meaning "circumstances beyond the control of the applicant".

From the spirit of these adjudications it would seem that Marconi's successes should not be given such consideration as would make up for the deficiencies in a showing of unavoidable delay. If Marconi had failed to transmit messages from Poldhu to Spezzia and had not been honored by the Czar of Russia, the showing submitted by the attorney would be entitled to just as much consideration.

It seems that ex parte McElroy, 101 O. G., 2823, cited in the Examiner's answer of October 15th as authority for holding that a showing of unavoidable delay must cover the entire period, has been objected to by the attorney as not on all fours with the present case. Attention is, therefore, respectfully called to the following decisions of the Commissioner of Patents, which show that the uniform and [fol. 3622] settled practice of the office under Rule 72 has been to require "a showing of facts covering the entire period" in order to warrant the revival of an abandoned application:

Ex parte Root, 40 O. G., 811.
Ex parte Fenno, 52 O. G., 1665.
Ex parte Edison, 56 O. G., 1061.

Ex parte Murray, 56 O. G., 1060.
Ex parte Clarke, 61 O. G., 286.
Ex parte Heine, 64 O. G., 1006.
Ex parte Warren, 96 O. G., 2410.

It has been maintained that this case should be revived because Marconi's British patent No. 7777 of 1900, will bar the filing of a new application for the subject matter disclosed in this case. Not only said British patent but also Belgian patent No. 152,840 and French patent, No. 308,204, and it is believed other foreign patents for the same invention, will bar such new application, and this very fact furnishes additional reason why the application should not have been permitted to become abandoned.—ex parte Pietzner, 103 O. G., 2171.

The proposed amendment submitted with the supplemental affidavit of October 24, 1903, removes the objection to the proposed amendment of October 12, 1903, in that it cancels therefrom the method claims and the new matter referred to in the Examiner's answer of October 15, 1903, but the amendment of October 12th as amended is not such as would put this case in condition for allowance.

No reason is seen for favorably recommending this petition.

Very respectfully,

WM. A. KINNAN,
Acting Examiner, Division XVI.

G.K.W.

[fol. 3622] Serial No. 36010.

Paper #13

Filed Nov. 4, 1903

Docket Clerk, Nov. 4, 1903, U. S. Patent Office

United States Patent Office

In the Matter of the Application of GUGLIELMO MARCONI for a Patent for Apparatus for Wireless Telegraphy: Filed November 10, 1900; Serial No. 36,010

Before the Commissioner, by Petition

Brief on Behalf of Marconi

This is a petition filed by the Attorneys for Marconi, that this Application be revived as a pending Application.

under the provisions of the Statutes of the United States.

On October 12, 1902, this petition was filed, and on October 15th the Examiner submitted an answer, recommending that the petition be denied. Thereupon, under date of October 24th, we submitted an additional affidavit, in the nature of a supplemental affidavit, and under date of October 26th, the Examiner has held that "no reason is seen for favorably recommending this petition."

The one-year time limit provided by the statute expired on June 3, 1903.

In the petition as filed on October 12th, it was shown that Marconi did not arrive in the United States from abroad, [fol. 3624] until the 27th day of January, 1903. The petition supported by a duly verified affidavit, explains in detail the several attempts, beginning on the day he arrived, January 27th, 1903, which the attorneys made to secure sufficient information from him about this highly technical invention, to completely and satisfactorily answer the last office action of June 3, 1903.

It was shown that not only was one attempt made, but several attempts were made between January, 1903, and June of the same year, although Marconi was not in this country at any time between those dates, except from the 27th to the 31st of January, 1903. It is further shown that when this application was called to his attention in January, 1903, Marconi stated that he was unable to fully and completely answer this office letter until he had consulted some documents which were then in England.

In view of the many attempts made to secure information to amend this case between January and June, 1903, it is satisfactorily explained why the amendment was not filed during this period, and therefore the Examiner's statement of October 15th makes no criticism as to the sufficiency of the excuse for non-action after January, 1903, except that the Examiner suggests that "some action on the partial information obtained from Marconi on January 27, 1903, might have been submitted by the attorneys between May 13th and June 3, 1903, that would have saved the case from abandonment.

[fol. 3625] We can hardly suppose that the Examiner recommends or approves of the practice of making a piecemeal reply to an Office letter, and one known to be in the nature of a piecemeal reply, and insufficient at the time of

making it, especially when, as in this case, detailed and accurate information on which to base what was believed to be an adequate reply, was promised in a short time.

The only information which Mr. Marconi gave us on January 27, 1903, was a very brief verbal one, and as Mr. Marconi informed us that upon his return to England he would send us a full written report, after he had consulted with his documents there, we had no records to go by to formulate an amendment between May 13, 1903, and June 3, 1903, as suggested by the Examiner. The verbal information which Mr. Marconi *did* give us on January 27, 1903, was not sufficiently clear or well enough understood by us to have answered the last Office action.

The Examiner, in his letter of October 26th, practically admits that the delay from January to June of 1903 was "unavoidable".

But the Examiner, in his letter of October 5th, recommends that "the petition be denied", because it had not *then* been shown that the delay in filing the amendment from June of 1902, to January of 1903, was "unavoidable" [fol. 3626] on the authority of ex parte McElroy, 101 O. G. 2823.

We therefore filed a supplemental showing as to where Mr. Marconi was during the period between June of 1902 and January of 1903, when he first arrived in this country, although we did not believe, and do not believe now, that the decision in the McElroy case is applicable to the present case.

This supplemental showing is contained in an affidavit, duly verified under date of October 22*th*.

It shows that Marconi was not in the United States from the time of the last office action, June 3, 1902, until January of 1903.

Marconi was, therefore, unavailable for consultation.

It was further shown that early in July, 1902, Mr. Marconi left England, where the present owners of this Marconi application reside, and went to Italy, where he was engaged in conducting important experiments upon the Italian war-ship "Carlo Alberto," which had been loaned him by the Italian Government for that purpose. It was further shown that these experiments lasted for several weeks in the Mediterranean Sea, upon this war-ship, and that thereafter, Mr. Marconi sailed up the Baltic Sea upon this same

war-ship to Cronstadt, Russia, still continuing his experiments, which lasted sometime in addition.

The Examiner, in his letter of October 26th, has criticised [fol. 3627] this showing as to Marconi's movements during this period, as immaterial and irrelevant, because the Examiner claims that "Marconi was unable to attend to his patent office business by reason of his other business interests."

It is submitted that this showing is both material and relevant. It is material and relevant because it explains where Mr. Marconi was during the Summer and early Autumn of 1902, and shows that Mr. Marconi was more than 3000 miles away from his attorneys, and also shows that he was many hundreds of miles away from the owners of his patent. He was, therefore, unavailable during this period for consultation.

It is also shown in the supplemental affidavit that Mr. Marconi was expected by his attorneys to come to the United States early in the Fall of 1902, but that he was delayed from time to time by this important business, and that he only returned to England for a very short time after completing his experiments on the "Carlo Alberto" in the Baltic Sea, and then sailed for Canada upon the same Italian war-ship, which was still being loaned him by the Italian Government to continue his experiments while crossing the Atlantic, and that he arrived on this war-ship in Canada about December of 1902.

While, therefore, Mr. Marconi was on this war-ship conducting his experiments in the Mediterranean Sea, the Baltic Sea, and the Atlantic Ocean, it is only fair to say that he was "unavoidably" prevented from taking action. [fol. 3628] It is submitted, therefore, that not only has it been shown that the delay from January to June, of 1903, was "unavoidable," but also that the delay from June, 1902, until January of 1903, was also "unavoidable".

The Examiner practically claims that during this first period of the year's time, Mr. Marconi should have given up conducting his experiments for the Italian Government, on the "Carlo Alberto," for the purpose of attending to his Patent Office business.

This is what the Examiner's contention amounts to.

It is not believed that this is sound.

While it may be true that where an inventor resides in the vicinity or near his attorneys and is engaged in *ordinary*

mercantile business, that an excuse of "other business engagements" as a reason for not attending to his Patent Office matter, is not a good excuse, yet where, as in the present case, it is shown that the inventor resides more than 3000 miles away from his attorneys and that during the period of time in question he was conducting experiments for the Italian Government, a different and more reasonable view of the facts should be taken. The rule certainly does not contemplate any obligation by the applicant to travel hundreds of miles during the first part of the period for action and come from foreign countries when there was every reasonable expectation, and a continuing expectation, that his business abroad would allow him ample time after it was finished to take the required action.

We submit that the decisions which the Examiner cites in his letter of October 26th do not apply to this case.

[fol. 3629] In ex parte McElroy, 101 O. G. 2823, it was held that the delay was not "unavoidable" because it had been shown that it was the "*practice*" of the applicant to *only* amend his applications within the last week or two of the time limit, and that in this case he was unable to do so because he had been stricken during this last week or two with typhoid fever. The Commissioner therefore held that the delay was "intentional."

The McElroy case does not apply to the present case. First, because it is shown that it has not been the "practice" of this applicant to amend his applications only within the last week or two of the time limit (the last amendment having been made about two months after official action); and second, because it has been shown that the attorneys made repeated efforts to obtain sufficient knowledge to amend this case during the whole last six months of the time limit, the first being made five months before the year's time expired.

In ex parte Root, 40 O. G. 811, it appeared that only twelve days before the time limit had elapsed, the attorneys made a *single* effort to have this case amended, which was unsuccessful. This effort consisted in writing a letter to another lawyer in Washington. The Commissioner said:

"The writing of this note and its failure to come into Mr. M. F. Halbeck's hands at an earlier date, constitute the *sole* reason presented to bring the case within the statute for reinstatement of applications abandoned for want of prosecution. * * * It is therefore a case in which the

entire period of two years is allowed to expire without any attempt at definite action." (Italics ours).

This case is no precedent, therefore, for the Marconi case: first, because the engagements and absence from home were exceptional and because here the attorneys made not one, but several attempts; and second, because these attempts were not made during the last week or two of the time limit [fol. 3630] but at least as early as five or six months before the time limit expired.

Ex parte Fenno, 52 O. G. 665 was a case following the decision in ex parte Root, and the only showing in this case was that during the last *month* of the time limit, the applicant was in such a bad financial condition that he was unable to pay for an amendment being filed. The Commissioner says:

"It is true that he states that in April, 1890, he was short of money and had hard work to get what he needed; but there is no showing as to what his financial condition was during the preceding twenty-three months. Ex parte Root, C. D. 1887, 81."

Here again was a case where no effort was made until the time limit was about to expire and then the showing was that only a single effort was made.

Such is not the situation, as we have pointed out, in the present instance.

Ex parte Edison, 56 O. G. 1061, likewise follows ex parte Root, since the only showing in the Edison case was that during the time limit the attorney once wrote to the Patent Office for a copy of a previous action and the Commissioner held that this letter of Edison's attorney was not an "action" as required by the statutes.

Ex parte Murray also follows ex parte Root. In the Murray case it did not appear that the attorneys had *ever* attempted during the two years' period to amend the case or to get sufficient information from the applicant to amend the case.

[fol. 3631] Such is not the situation in the case at hand.

In ex parte Clarke, 61 O. G. 286, the petition was denied because "the delay has been more than *four* years, and applicant only accounted for one." Furthermore, it did not appear that even during this one year, either applicant or the attorney had endeavored to amend the case or secure

such information as would have enabled the attorney to amend the case.

Ex parte Heine, 64 O. G. 1006, merely follows ex parte Root, which we have shown is clearly distinguishable from the present case.

Ex parte Warren, 96 O. G. 2410, was another case where the applicant's attorneys waited until within a week or two of the time limit before filing a proper amendment or took an appeal. The Commissioner states:

"By *intentionally* postponing proper action until the last of the time allowed, the attorneys assumed the risk of accidents, mistakes, or other circumstances which might then prevent action." (Italics ours)

It is shown in the Marconi case that the attorneys did *not* wait until the last of the time limit, but at least five months prior to that time endeavored to get from the inventor such information as would enable them to properly amend the case, but that the inventor was unable to give this information, and that during the succeeding five months not one, but several additional attempts were made to secure this information."

[fol. 3632] We have shown, therefore, that not one of the cases cited by the Examiner is applicable to the case at bar.

We have further shown that not only was the delay during the last six months of the year "*unavoidable*," but that the delay during the first six months as well, was "*unavoidable*."

Apparently, the supplemental showing which we have made has somewhat altered the Examiner's opinion as to the equities of this case, because in his first letter of October 15th, he recommended that the "petition be denied," while in his letter of October 26th, the Examiner merely states that "no reason is seen for favorably recommending this petition."

It is respectfully submitted, therefore, that in view of the detailed showing now presented in this case as to the efforts made to amend the case, and as to the whereabouts of the inventor, Marconi, during the whole period of the year's time, that the petition to revive this application should be granted.

Respectfully submitted,

BETTS, BETTS, SHEFFIELD & BETTS,

Attorneys for Marconi.

Apparatus for Wireless Telegraphy.

Petition.

Application filed November 10, 1900, No. 36,010.

Messrs. Betts, Betts, Sheffield & Betts and Mr. T. E. Robertson for applicant.

This is a petition for a ruling that the above-entitled application is not abandoned, notwithstanding the fact that no action was taken in prosecution thereof for more than one year. It is contended that the delay in prosecution was unavoidable.

The last office action was dated June 3, 1902, and no reply was received until this petition was filed on October 12, 1903.

The facts relied upon as showing that the delay was unavoidable are set forth in two affidavits by one of the attorneys. It is said that the examiner's letter raised certain technical questions, which Marconi himself could best answer and that:

"it was decided to await his arrival in this country before submitting the questions raised by the examiner's letter to him."

It is said further that Marconi did not, in fact, come to this country until January 27, 1903, at which time the papers in the case were submitted to him and he then gave the at- [fol. 3635] torneys some information but not enough to enable them to make a completely responsive action in the case. It is said that Marconi found it necessary to consult certain records in London before he could furnish all of the

information necessary. Marconi then left this country for Europe, and thereafter the attorneys wrote two letters to his company asking for information and the papers. On April 11, 1903, they received a letter from the company saying that the "affidavits" had been despatched, but they were never received. Two more letters were written to the company, and on July 3rd a cablegram was received, saying that Marconi was ill and that the papers could not be forwarded at once. On August 21st the papers were received, but were accompanied by no remarks or explanation by Marconi. Marconi was in New York from September 28th to October 3rd, and the information desired was then available.

This showing attempts to excuse the failure of the attorneys to act by the statement that it was necessary to consult the inventor, but no effort whatever was made to consult the inventor for seven months after the office action. He was consulted in January, 1903, however, and assuming that he was the one then called upon to act, there is no satisfactory explanation why he did not furnish the information desired. The suggestion is made that he was very busy upon other matters which he seems to have regarded as more important, but this is not a sufficient excuse for inaction. It does not appear that he was any more busy then than at any other time. It appears merely that he was a busy man, and by choice devoted his attention to other matters instead of this. The cablegram as to Marconi's illness was after the application was abandoned, and there- [fol. 3636] fore it does not appear that the illness had anything to do with the failure to act within the year.

After the examiner had answered this petition, the attorney presented a supplemental affidavit, attempting to explain the inaction for the first seven months of the year fixed by law for action. It was there said:

"Mr. Marconi was not, unless for very brief periods of time, in a position to take up the amendment of his application and could not be visited by his attorneys."

It is said that in July, 1902, Marconi went to Italy, and a few weeks later to Russia, and expected to return to England and then go to Canada in September, 1902. He did not, in fact, reach Canada until December, 1902, and ar-

rived in this country on January 27, 1903. The attorneys were awaiting his arrival in this country, and say:

"It was always, however, represented to us that he was coming to this country soon."

The movements of Marconi before coming to this country might be pertinent if they were what prevented the attorneys from communicating with him, but that does not appear to have been the case. No effort seems to have been made to communicate with him. It seems clear that the consultation might have been conducted by correspondence and that in fact seems to have been the intention after the interview of January 27, 1903.

The year allowed by law for action is ample, and it is only under very exceptional circumstances that a delay for a longer period is justified. The mere plea that the inventor was busy upon other matters and did not have time to devote to the case under consideration, cannot be accepted as a showing that the delay for such a long time was unavoid-[fol. 36,37] able. The word "unavoidable" in the statute means more than that to act would have been inconvenient.

Since the delay in this case is attempted to be explained on the ground that Marconi did not furnish the necessary information, it cannot be held that the delay was unavoidable, in the absence of a showing by him of good reasons why he did not furnish the information.

The petition is denied.

F. I. ALLEN,
Commissioner.

Filed February 24, 1904

Docket Clerk, Feb. 24, 1904. U. S. Patent Office.

United States Patent Office

In the Matter of the Application of Guglielmo Marconi, for Patent for Apparatus for Wireless Telegraphy, Serial No. 36,010. Filed November 10, 1900.

New York, February 19, 1904.

Hon. Commissioner of Patents,
Washington, D. C.

Sir:

This Application was rejected on the 3rd day of June, 1902. On the 12th day of October, 1903, petition was filed asking that the Application be declared a pending Application under the authority vested in your Honor, by the provision of Section 4894 of the Revised Statutes.

On December 2, 1903, this petition was denied, in the absence of a verified showing by Marconi himself.

We respectfully ask for a re-consideration of the foregoing petition in view of the supplemental showing contained in the affidavits of Guglielmo Marconi, L. F. H. Betts and T. E. Robertson, filed herewith.

Respectfully submitted,

BETTS, BETTS, SHEFFIELD & BETTS,

Attorneys for Applicant.

[fol. 3639] In the United States Patent Office

In Reapplication of Guglielmo Marconi, Serial No. 36,010. Filed November 10, 1900. Apparatus for Wireless Telegraphy.

London, England, ss:

Guglielmo Marconi, being duly sworn, deposed and says:

I am the applicant in application for United States Letters Patent Serial No. 36,010, filed November 10, 1900, for apparatus for wireless telegraphy.

In the latter part of the year 1901, and early in the year 1902, I was in America, and at that time succeeded in transmitting signals from Poldhu in Cornwall, to St. John's, Newfoundland by my system of wireless telegraphy, and satisfied myself that it was possible to transmit messages on a commercial scale. Early in 1902 I was, however, compelled to return to England, but it was my intention to return to America as soon as possible for the purpose of installing a station for the commercial transmission of signals across the Atlantic Ocean, which station was to be installed at Cape Breton, Nova Scotia to connect with our station at Poldhu, Cornwall, on the one hand, and with a station at Cape Cod, U. S. A., on the other hand. As time went on, it became more and more important to the interests of my various companies, that this long distance transmission station should be established, and I was con-

[fol. 3640] stantly urged to return to America for this and other purposes connected with my interests in America, and particularly in the United States. I was constantly expecting to make this trip to America, but it became necessary to postpone my departure from time to time.

In June, 1902, an opportunity presented itself to obtain the use of the "Carlo Alberto", a ship of the Italian Navy, for the purpose of carrying out tests of my system, and I determined to make use of this opportunity to make tests of long distance transmission over land and sea. Accordingly and on the 18th day of June, 1902, I commenced my experiments on the "Carlo Alberto" round the Coast of England, which were continued uninterruptedly between this ship and a number of my stations, i. e. Poldhu, The Lizard, Poole, Niton, etc., until the 6th July.

On the 6th July I left Dover on the "Carlo Alberto" for Cronstadt, carrying out experiments during the entire voyage, and on 22nd July I sailed from Cronstadt to England, where I arrived on August 1st. All the time from August 1st to the 24th I was busily engaged in experiments preparatory to another voyage on the "Carlo Alberto". It had been my intention to sail from there to America, for the purpose of installing the long distance transmission station there, but decided to return first to the Mediterranean, and on August 25th, 1902, I sailed from England for the Mediterranean on the "Carlo Alberto", with the intention of returning to England about the first week in September, and of proceeding from there to Cape Breton, and after establishing communication between Cape Breton and Poldhu, to proceed to Cape Cod, U. S. A.

I am informed and believe that my representatives in [fol. 3641] America were notified of this change of plans. During all of the time that I was carrying on these tests on the "Carlo Alberto", I was steaming from place to place, and often, on account of the uncertainty of my movements, it was impossible for correspondence to reach me.

These experiments in the Mediterranean occupied my time until the 20th day of September when I returned to England, and on the 20th day of October, 1902, I sailed from England for Cape Breton, arriving there on the 31st day of October, 1902. From that time on, I was constantly expecting to leave Cape Breton, for New York City, and I am informed and believed that certain important matters which demanded my attention in New York, were postponed from time to time, pending my arrival. The experiments at Cape Breton occupied a longer time than I had anticipated, and I did not leave there for New York until the 14th day of January, 1903. In the meantime I received at Cape Breton a letter from my attorneys, Messrs. Betts, Betts, Sheffield & Betts, bearing date of January 3rd, 1903, asking for certain information which they desired in regard to my application serial No. 36,040, for the purpose of making an amendment in that application, and of overcoming the objections urged thereto by the Examiner in the United States Patent Office. On January 10, 1903, I telegraphed to Messrs. Betts, Betts, Sheffield & Betts, to send me copies of the papers in this case, and under date of January 10th they mailed these copies to me, and they were duly received at Cape Breton.

On examining these papers, I discovered that I would be unable to answer the questions presented by the Action of the Patent Office, dated June 3rd, 1902, without resort to my papers stored in London, and for this reason I postponed any report on this application until I should arrive in New York City.

[fol. 3642] I arrived in New York City about January 23, 1903, and remained there several days, during which time I consulted with my attorneys, Messrs. Betts, Betts, Sheffield & Betts, and I discussed with Mr. L. F. H. Betts, of that firm, this application serial No. 36,010, and I promised to send to him the information which was necessary, upon my return to London, and upon my examination of the papers stored there. At this time I requested Mr. Betts to write a letter to me, in London setting forth exactly the papers and information which were necessary in connection with this application, in order that I might prepare such papers in London. Upon my arrival in London, it became absolutely necessary for me to give my attention to pressing matters in connection with the development of my inventions in wireless telegraphy. Mr. Betts had written the letter which I had asked for, under date of January 27, 1903, and I took advantage of the first opportunity to prepare the papers asked for in that letter, and prior to April 4, 1903, I prepared and despatched to Messrs. Betts, Betts, Sheffield & Betts, the necessary papers. These papers were left in the hands of the Notary to be sent to Messrs. Betts, Betts, Sheffield & Betts, about the end of March or the beginning of April 1903. On April 4, 1903, I received a telegram from the Marconi Wireless Telegraph Company, Limited, of London, asking me if the papers in this case had been prepared and sent, and I informed Marconi's Wireless Telegraph Company, Limited, that these papers had been sent, and I am informed and believe that this information was imparted to Messrs. Betts, Betts, Sheffield & Betts, by that Company.

On the 22nd day of May 1903, a letter was received, bearing date May 13, 1903, from Messrs. Betts, Betts, Sheffield & Betts, by Marconi's Wireless Telegraph Company, Limited, [fol. 3643] of London, stating that these papers had never been received and asking that they be sent to them immediately. At that time I was in Italy, at Pisa, where I had been ordered by Dr. Mazzoni, of Rome, for a recupera-

tive rest, in order that I might recover from an illness from which I had suffered since about April 20th. At this time I was unable to attend to any business matters whatever. On my return to England, in May, 1903, I had not recovered from my previous illness, and was, by doctor's orders, again confined to bed for a week or ten days. In fact, during the two months from about the middle of April to about the middle of June, 1903, I was not only incapacitated by illness, from attending to patent business, but was, much to my own inconvenience and that of my companies prevented from attending to many other urgent matters of business.

As soon as I was able to attend to this matter, and in the month of August, 1903, I forwarded to Messrs. Betts, Betts, Sheffield & Betts, papers which I believed would be sufficient to meet their requirements. Thereafter, I arrived in New York City, on September 28, 1903, and remained there until October 3, 1903, and at this time the full information was given to Messrs. Betts, Betts, Sheffield & Betts, and I am informed and believe that the necessary amendment was immediately filed by them.

GUGLIELMO MARCONI.

February, 1904.

[SEAL.]

G. F. WARREN,
Notary Public.

[NOTARIAL SEAL.]

(Foreign Revenue Stamps.)

[fol. 3644] Consulate-General of the United States of America for Great Britain & Ireland at London

I, Richard Westacott Acting Consul-General of the United States of America at London, England do hereby make known and certify to all whom it may concern that George Frederick Warren who hath signed the annexed Certificate, is a Notary Public, duly admitted and sworn and practising in the city of London, aforesaid, and that to all facts by him so done full faith and credit are and ought to be given in Judicature and thereout.

In Testimony Whereof, I have hereunto set my hand and affixed my Seal of Office at London aforesaid, this Third day of February in the year of our Lord One Thousand Nine Hundred and Four.

[SEAL.] RICHARD WESTACOTT,
Acting Consul-General.

[CONSULAR SEAL.]

[fol. 3645] United States Patent Office

In re Application of Guglielmo Marconi No. 36,010. Filed Nov. 10, 1900. Apparatus for Wireless Telegraphy

STATE OF NEW YORK,
County of New York, ss:

Louis Frederick Holbrook Betts, being duly sworn, deposes and says:

I am a member of the firm of Betts, Betts, Sheffield & Betts, attorneys for Guglielmo Marconi in the above-entitled application.

When I received the Office action bearing date of June 3, 1902, in the above-entitled application, I had been informed and believed that it was Mr. Marconi's intention to come to America for the purpose of establishing a long-distance transmission station at Cape Breton, Nova Scotia, and also for the purpose of establishing a station at Cape Cod, Massachusetts, and I was aware that he was being urged to come to America for this purpose, at the earliest possible moment, since it was of considerable importance to the interests of the Marconi Wireless Telegraph Company of America that this long-distance station should be installed. I was also aware that Mr. Marconi intended to visit New York at the time of his contemplated trip to this country, and that there were many matters awaiting [fol. 3646] his consideration in New York, and I believed that Mr. Marconi was likely to leave England for this country at any time. During the early part of July, 1902, it came to my knowledge that Mr. Marconi had left England for Cronstadt, Russia, for the purpose of carrying out certain experiments on the "Carlo Alberto", in the Baltic Sea, a ship belonging to the Italian Navy, and loaned to Mr.

Marconi by the Italian Government. It was expected in America that as soon as Mr. Marconi completed his experiments he would sail for America for the purpose of establishing a long-distance transmission station.

On the 21st day of August, 1902, a letter was addressed to this office by Mr. H. Cuthbert-Hall, Managing Director of Marconi's Wireless Telegraph Company, Ltd., of London, which letter was duly received, and with this letter was received a copy of a letter bearing date of August 16, 1902, addressed to the Marconi Wireless Telegraph Company of America, which letter contained the following information:

"You may possibly have learned from announcements in the press that Mr. Marconi is going to the Mediterranean next week on the 'Carlo Alberto', and will probably take the opportunity of making further experiments with the Poldhu Station over land and sea combined.

"We have thought that you might be surprised that any engagement should now be entered into which tends further to postpone the proposed trans-Atlantic transmission. This engagement has, however, been entered into in the interests not only of this Company, but of all the Marconi Companies. * * *

"* * * It is hoped that he" (Mr. Marconi) "will return to England about the first week in September; he will then proceed to Cape Breton, and after communication has been established between that Station and Poldhu, he will then go on to Cape Cod and start the service there".

This letter, though it informed me that Mr. Marconi [fol. 3647] would not be in this country so early as I had expected, led me to believe that he would be available for a personal interview not later than the 1st of October, 1902, and it also informed me that he would be, in the meantime, traveling from place to place on the "Carlo Alberto," and I knew that it would be practically impossible to communicate with him, or to secure any technical information from him.

Mr. Marconi did not, in fact, complete these experiments on the "Carlo Alberto" and leave England for Cape Breton until the middle of October, but during all the time from the 1st of June until he actually sailed from England it was represented to us that he was about to come to this country, and we knew that he was steaming from place to

place on the "Carlo Alberto", and that it was well nigh impossible to communicate with him.

Mr. Marconi did not arrive at Cape Breton until about the 1st of November, 1902. I am informed and believe that the exact date was the 31st day of October, 1902. In my affidavit, executed the 22nd day of October, 1903, in support of the petition to revive this application, I stated that Mr. Marconi did not arrive in Cape Breton until December, 1902. This date should have been "until November, 1902", and the date December, 1902, was included in my prior affidavit by mistake.

My partner, Mr. Frederic H. Betts, was at this time a director in the Marconi Wireless Telegraph Company of America, of which Company Mr. Marconi was, and still is, also a director, and in order to show that our office was kept informed as to Mr. Marconi's movements, and that [fol. 3648] we had good reason to expect him in New York immediately, I will state that the regular meeting of the Board of Directors of the Marconi Wireless Telegraph Company of America was postponed on October 28, 1902, for a period of two weeks, in the expectation that Mr. Marconi would be in this country at the end of that time.

Under date of November 13, 1902, we received a letter as follows:

New York, November 13, 1902.

Frederic H. Betts, Esq.,
120 Broadway, City.

DEAR SIR:

The regular meeting of the Board of Directors of Marconi Wireless Telegraph Company of America which was postponed on October 28th, 1902, for the farther period of two weeks, or pending the arrival of Mr. Marconi, was not held November 11th, 1902, there being no quorum.

It is now desired that the Directors consent to a further postponement of the said meeting for three weeks, pending the arrival of Mr. Marconi in New York.

Yours respectfully,

MARCONI WIRELESS TELEGRAPH
COMPANY OF AMERICA,
By C. J. STEEDMAN,
Secretary and Treasurer."

Under date of November 28, 1902, we received a second letter, as follows:

"November 28, 1902.

Frederic H. Betts, Esq.,
120 Broadway, City.

DEAR SIR:

By telegram dated November 23d, we are advised that Mr. Marconi will be detained at Glace Bay until about the 6th prox. Kindly signify on enclosed postal whether you prefer that the meeting of the Board of Directors be further adjourned until, say, December 9th, or indefinitely postponed to be held upon special call on Mr. Marconi's arrival here.

Yours very truly,
MARCONI WIRELESS TELEGRAPH
CO. OF AMERICA,
By J. BOTTOMLEY,
Secretary."

The information contained in these letters was communicated to me, and being thus in almost weekly expectation of the arrival of Mr. Marconi in New York, and believing, [fol. 3649] as I did, that it was of the utmost important that the very technical questions presented by the Patent Office action of June 3, 1902, should be discussed at a personal interview with Mr. Marconi, because of his peculiar knowledge of the subject-matter involved, I did not, at this time, write to Mr. Marconi asking for this information. In fact, during the time from June, 1902 to January, 1903, it appeared that Mr. Marconi would be in New York City about as soon as it would be possible to communicate with him by letter, because, since he was abroad travelling on the "Carlo Alberto", I knew that letters to him would necessarily be very greatly delayed and would perhaps not reach him at all, and after he arrived at Cape Breton he expected to leave there at any moment.

However, in view of the repeated postponements of his departure from Cape Breton, I finally wrote to him there, under date of January 5, 1903, asking him for the desired information in regard to this Application No. 36,010, although we still had six months to amend the same. On

January 10, 1903, I received from him a telegraphic request for copies of the papers in this case, as follows:

"Glace Bay N. S. Jan. 10.

Mirage New York

Send set papers 36010 addressed to Cape Cod station.

Marconi."

These copies were sent to him the same day, with a letter reading as following:

"January 10, 1903.

Guglielmo Marconi, Esq.,

Cape Cod Station, Marconi's Wireless Tel. Co., Ltd.,

Cape Cod, Mass.

DEAR SIR:

Your telegram of January 10th from Glace Bay, has been received.

In accordance therewith, we send to you herewith complete set of papers in the matter of your Application No. 36,010.

[fol. 3650] "Will you please let us have your views in relation to this case at your earliest convenience.

Yours very truly,

B., B., S. & B."

About the middle of January, Mr. Marconi finally left Cape Breton for Cape Cod, and arrived there, as I am informed and believe, on January 16th, and on January 23rd, he arrived in New York City. He remained here several days, and at that time discussed with me this application No. 36010, and informed me that he would not be able to furnish the desired information without consulting his papers stored in London. I accordingly reduced to writing a statement of the information and papers which we desired, in the form of a letter to Mr. Marconi, bearing date of January 27, 1903. This letter was dispatched to Mr. Marconi, on January 27, 1903.

Later, on March 20th, our firm wrote *both* to Mr. Marconi and to Marconi's Wireless Telegraph Company, Ltd., urging that the information referred to, together with the papers, be sent as soon as possible. These letters read as follows:

"Guglielmo Marconi, "March 20, 1903.

c/o Marconi's Wireless Tel. Co., Ltd.

18 Finch Lane, London, England.

DEAR SIR:

Referring to your United States Application, serial No. 36,010 (for tuning the circuits at both the transmitting and receiving stations), you will recollect that, when you were here, we called your attention to the fact that the Examiner had rejected your Claims on the Tesla United States Patents, on the ground that you used the Tesla form of oscillator in connection with your wireless telegraph system. At that interview, you gave us, offhand, some of the reasons which distinguish your apparatus from that of Tesla, and you were to send us more information on this point. Accordingly, we asked you in our letter of January 27, 1903 (see page 4), to give us a full explanation, in detail, of the radical difference between your system and Tesla's.

[fol. 3651] "We have not heard from you in connection with this matter, and should be pleased to receive your views at the earliest day. The Application should be hurried as much as possible, having remained pending in the Patent Office for two and a half years. Another reason why this matter should be disposed of now, is that the Patent Office Examiner has, in connection with Dr. Fleming's Application, raised the point that he also uses the Tesla oscillator. Dr. Fleming, of course, uses your form, and the same reasons given in connection with your Application No. 36,010, will also be pertinent in connection with the reply to be filed in Dr. Fleming's case.

"If unable to send the desired information now, will you kindly indicate when you hope to do so.

Yours very truly,

BETTS, BETTS, SHEFFIELD & BETTS,

W. H. B."

"March 20, 1903.

"Marconi's Wireless Telegraph Co., Ltd.
18 Finch Lane, London, England.

DEAR SIRS:

Referring to Mr. Marconi's Applications Nos. 36,010 and 82,856, for United States Patents, and which have been pending since November, 1900, and November, 1901, respectively, we wrote to Mr. Marconi under date of January 27, 1903 (see copy of letter enclosed), asking him to consider certain positions taken by the Examiner in the United States Patent Office, in reference to the second-named Ap-

plication, and to send us an affidavit by himself, and possibly one by Dr. Fleming, pointing out fully the theory of operation of the apparatus of said Application, and also distinguishing the oscillator employed by him from that described by Tesla in the United States Patent sent with our letter. We now enclose a copy of the said Tesla Patent.

"We have not heard from Mr. Marconi in response to our letter, and are very anxious that the matters referred to should have early attention. Will you please, therefore, ask Mr. Marconi, at his earliest convenience, to give our letter of January 27, 1903, his complete considera'ion, and to have his views, as well as those of Prof. Fleming, sent to us in the form of affidavits.

"There is need for haste in prosecuting both of said Applications, especially in the case of No. 82,856, in which we may be able to file certain claims, somewhat broadly covering the employment of a single aerial with a plurality of transmitting or receiving branches connected thereto, thus bringing on an Interference which will decide priority of invention as between Mr. Marconi and other claimants.

Kindly acknowledge receipt of this letter.

Yours truly,

BETTS, BETTS, SHEFFIELD & BETTS,

W. H. B."

[fol. 3652] These were the only letters we wrote to either of these parties on that date, and in reply we received, on or about April 11th, the following letter:

"London, 4th April, 1903.

Messrs. Betts, Betts, Sheffield & Betts,
120 Broadway, New York.

DEAR SIRS:

In connection with your letter of March 20th I have this morning wired to Mr. Marconi who is at present at Poldhu, asking him if the affidavits sent with your letter of Jan. 27th had been attended to and returned. Mr. Marconi wires in reply "Yes affidavits despatched by Notary".

Yours faithfully,

MARCONI'S WIRELESS TELEGRAPH CO., LTD.,
HENRY W. ALLEN,
Secretary & Asst. Manager."

These papers or affidavits were never received by us.

After waiting a reasonable time for the receipt of these papers, which were necessary in connection with Application No. 36,010, we again wrote to Marconi's Wireless Telegraph Company, Ltd., on May 13, 1903, in which we said:

"May 13, 1903.

"Marconi's Wireless Telegraph Company, Ltd.,
18 Finch Lane, London, England.

GENTLEMEN:

Referring to our two letters to Mr. Marconi under date of March 20th, and to our letter to your Company of the same date, will you please let us know when we may expect to have the affidavits or statements by Mr. Marconi relative (1) to the differences between the Marconi system and the Tesla system, and (2) relative to the system which employs one aerial for the reception or transmission of several messages simultaneously.

"As we wrote you at that time, two of Mr. Marconi's United States Applications are being held up awaiting these affidavits or reports, and we are also delaying action in the matter of the two applications filed on behalf of Prof. Fleming.

Yours very truly,

BETTS, BETTS, SHEFFIELD & BETTS,
W. H. B."

[fol. 3653] And again, in a fourth letter, dated June 5, 1903, we wrote as follows:

"June 5, 1903.

Marconi's Wireless Telegraph Company, Limited,
18 Finch Lane, London, England.

DEAR SIRS:

Referring to our two letters dated March 20, 1903, to Mr. Marconi, and our letter of the same date to you, we have not received the affidavits, arguments or instructions referred to therein.

As we have already stated, the two applications of Mr. Marconi and the two applications of Prof. Fleming, are

being held up until we receive the information requested in said letters.

Will you please have the answers to said letters forwarded to us as soon as possible?

Yours very truly,

BETTS, BETTS, SHEFFIELD & BETTS,

W. H. B."

In answer we received the following cablegram, dated July 3, 1903:

"July 3, 1903.

Mirage, New York.

"Affidavits Multiple Patents Delayed by Marconi's illness. Hope to send twentieth.

"HALL".

Upon receipt of this information, that Mr. Marconi had been ill, we took immediate steps to prepare a petition to the Commissioner of Patents, asking that he declare that the case had not become abandoned, since we believed that the delay in the case was such a delay as the Commissioner would be warranted in declaring "unavoidable", under the provisions of section 4894 of the Revised Statutes.

On July 8th, this petition, accompanied by an affidavit executed by myself, was forwarded to our representative in Washington, Mr. Thomas E. Robertson, of No. 605 Seventh Street. In a letter of July 9th, Mr. Robertson stated that this petition must be accompanied by an amendment, since the Commissioner of Patents had declared that he had no power to grant such a petition unless it was accompanied by an amendment. It was impossible for us to prepare this amendment without the necessary information from Mr. [fol. 3654] Marconi, and we were therefore compelled to await the arrival of the necessary papers.

On August 29, 1903, we received certain papers, but no remarks from Mr. Marconi. These papers did not convey sufficient information to enable us to make a full and complete response to the Office action of June 3rd. We were aware that Mr. Marconi intended to be in New York sometime during the month of September, 1903. Mr. Marconi was first in New York from September 28th to October 3rd, and we then secured from him the desired information. We thereupon prepared an amendment and argument in

reply to the last Office action on this application, which amendment, with the argument relating thereto, covers fifteen large typewritten pages, and is completely responsive to the last Office action. This amendment was forwarded to Mr. Robertson, in Washington, on October 6, 1903, and on October 12th the amendment and petition were filed in the Patent Office.

On December 2, 1903, the Commissioner of Patents denied this petition, and a copy of his decision was received by us on December 3rd. On December 5th we forwarded to Marconi's Wireless Telegraph Company, Ltd., at London, a copy of this decision, together with a copy of the petition, affidavits and brief, and asking that they ascertain if Mr. Marconi could make a satisfactory showing to explain the delay on his part, which delay the Commissioner of Patents had, in his decision, remarked upon as fatal to the petition. In this letter to the Marconi Company we also asked for further instructions in regard to this case. Under [fol. 3655] date of December 30, 1903, Mr. Marconi wrote us in regard to this application, saying that he would prepare a statement showing that the papers which he sent us in April, 1903, were the papers which we desired for use in this application, and also showing that he was unable to attend to business on account of illness during a considerable portion of the Spring of 1903. This statement was forwarded to us under date of January 6, 1904, and was received by us in due course. On January 22nd we forwarded to Mr. Marconi a letter accompanied by a draft form of affidavit which we desired him to execute, and which was based on the information contained in his statement. This affidavit, duly executed, was received by us on the 15th day of February, 1904.

L. F. H. BETTS.

Subscribed and sworn to before me this 29th day of February 1904.

[SEAL.] JAMES COSGROVE,
Notary Public,
New York Co.

[NOTARIAL SEAL.]

[fol. 2656] In the United States Patent Office

In Re Application of Guglielmo Marconi, Serial No. 36,010. Filed November 10, 1900. Apparatus for Wireless Telegraphy.

District of Columbia,
County of Washington, ss:

Thomas E. Robertson, of Washington, in the District of Columbia, being duly sworn, deposes and says:

On the 9th day of July, 1903, I received from Messrs. Betts, Betts, Sheffield & Betts, of 120 Broadway, New York City, a petition, accompanied by a verified showing of Mr. L. F. H. Betts, for the revival of the above entitled application of G. Marconi; that this petition was forwarded to me with instructions to file in the Patent Office; that as no amendment accompanied the petition, I consulted the Law Clerk of the Patent Office regarding the matter and was informed that no matter how good the reasons for revival, the Commissioner invariably rules that under the law he has no power to revive any case in which an amendment is not presented;

That in view of the interview with the Law Clerk, the petition, with its verified showing, was not filed, but on the same day (July 9, 1903) I replied to the attorneys in [fol. 3657] fact informing them that an amendment would have to be filed with the petition.

A few days after this, on July 17, I received a letter from the attorneys in fact acknowledging the receipt of my letter and stating that they would re-forward the petition, with the amendment, as soon as the information arrived which they were expecting from Mr. Marconi who was then in Europe.

THOS. E. ROBERTSON.

Subscribed and sworn to before me this 24th day of February, 1904.

WM. H. DeLACY,
Notary Public.

[fol. 3658]

Paper No. 16

Serial No. 36010

Brief

Filed March 3, 1904

Docket Clerk, U. S. Patent Office, Mar. 3, 1904

United States Patent Office

In the Matter of Application of Guglielmo Marconi. Serial No. 36,010. Filed November 10, 1900. For Improvements in Apparatus for Wireless Telegraphy.

Brief on Request for Reconsideration of Petition to Revive

Hon. Commissioner of Patents,
Washington, D. C.

SIR:

This Application was rejected on the 3rd day of June, 1902. On the 12th day of October, 1903, a petition was filed, asking that the case be declared a pending application, under the authority vested in your Honor by the provisions of section 4894 of the Revised Statutes.

On December 2, 1903, this petition was denied on the ground that the attorneys made no attempt to consult the inventor for seven months after the rejection, and on the ground that when the inventor was consulted he failed to reply, and has failed to explain why he did not reply.

We ask for a reconsideration of this decision, in view of the additional showing contained in the affidavits of Mr. [fol. 3659] Marconi and Mr. L. F. H. Betts, attached to the request for reconsideration.

We believe that if the exact circumstances which controlled the proceedings in this case are presented to your Honor, as they present themselves to us, your Honor will be satisfied that the delay was "unavoidable" in the sense in which that term is used in section 4894 of the Revised Statutes.

From a consideration of section 4894 of the Revised Statutes, and of the decisions interpreting that section, and particularly of the decisions rendered by your Honor, we believe that it will be held that this application is not

abandoned, if it can be shown that during the whole period from June 3, 1902, to June 3, 1903, the applicant, and his attorneys, were using such diligence in the prosecution of this application as is generally used and observed by prudent and careful business men in relation to their most important affairs, and that the failure to file the amendment within the year was caused by happenings beyond the control of the applicant or his attorneys (Ex parte Pratt, C. D. 1887, p. 32; Ex parte Hiene, C. D. 1893, p. 196; Ex parte Stuckgold, 106 O. G., p. 544).

We believe that such a showing can be made, and is made, by the affidavits accompanying the request for reconsideration.

In the decision of December 2, 1903, your Honor said:

[fol. 3660] "This showing attempts to excuse the failure of the attorneys to act, by the statement that it was necessary to consult the inventor, but no effort whatever was made to consult the inventor for seven months after the Office Action."

Your Honor further, referring to the supplemental affidavit filed, and the showing therein of the movements of Mr. Marconi during the Summer and Fall of 1902, said:

"The movements of Mr. Marconi before coming to this country might be pertinent if they were what prevented the attorneys from communicating with him, but that does not appear to have been the case. No effort seems to have been made to communicate with him. It seems clear that the consultation might have been conducted by correspondence and that in fact seems to have been the intention after the interview of January 27, 1903."

We believe that the affidavits attached to the request for reconsideration will show that Mr. Marconi's movements were exactly what prevented his attorneys from communicating with him.

On the 18th day of June, 1902, Mr. Marconi began his experiments on the "Carlo Alberto," and from that time to the 1st of November, he was continuously occupied with these experiments. We were aware that he was traveling from place to place, at sea, and that communications addressed to him had very slight chance of reaching their destination.

It is true that Mr. Marconi twice returned to England during the time from June to November of 1902. It is also true that if letters had been addressed to him there they might have reached him, provided they had been held by the Marconi Company, Limited, pending his arrival, and not forwarded to him, and so followed him from place to place.

His attorneys, however, had been led to believe, and did believe, that as soon as Mr. Marconi arrived in England [fol. 3661] he would immediately sail for America. This was certainly Mr. Marconi's intention when he left England on the "Carlo Alberto." Influenced by this belief, his attorneys felt that it would be useless to address a communication to him in London, since they supposed that such a communication would, at best, be handed to him as he was about to sail for this country, and would, therefore, not secure for them the desired information any sooner than such information would be secured by awaiting his arrival in New York.

It thus appears that the most expeditious, as well as the most satisfactory, way to communicate with Mr. Marconi was to await his arrival in New York.

Acting on this information, and using their best judgment, his attorneys refrained from writing to Mr. Marconi. They did not, of course, at any time suppose that the delay would extend over more than a week or so.

The attorneys watched with considerable interest the subsequent postponements of Mr. Marconi's arrival in New York, but each time his arrival was postponed it still appeared that he would leave for New York before a letter could reach him.

Finally, alarmed by the repeated postponements, his attorneys wrote him, in January, 1903, at Cape Breton, with the results set forth in the affidavits attached to this request.

It thus appears that during the whole time from June, 1902, to January, 1903, there was no period in which this case was put aside and intentionally delayed.

[fol. 3662] It is submitted that the affidavits show that during this period, the attorneys for Mr. Marconi, though they did not actually write any letter in this case, were, nevertheless, exercising the greatest care and diligence in its prosecution, because the case was under constant consideration and everything was being done that the most careful person would do in the prosecution of his most important

business affairs. The attorneys for Mr. Marconi were at all times in possession of information which indicated to them that the most expeditious procedure possible was to await the arrival of Mr. Marconi in New York.

In the decision of December 2nd, and discussing the conduct of Mr. Marconi, your Honor said:

"He was consulted in January, 1903, however, and assuming that he was the one then called upon to act, there is no satisfactory explanation why he did not furnish the information desired. The suggestion is made that he was very busy upon other matters which he seems to have regarded as more important, but that is not a sufficient excuse for inaction. It does not appear that he was any more busy than at any other time. It appears merely that he was a busy man, and by choice devoted his attention to other matters instead of this."

The affidavits filed in connection with this petition show that Mr. Marconi left this country after the 27th of January, 1903. He could not have arrived in London earlier than the 4th of February. Prior to the 4th of April he had prepared and despatched the papers necessary in this case. It is thus seen that these papers were prepared within two months.

It is *now* shown that Mr. Marconi did actually act in this case, two months before the year elapsed, but his efforts came to naught as we never received the papers Mr. Marconi sent.

[fol. 3663] When it is considered that it was necessary for Mr. Marconi to look up records, and to prepare carefully drawn papers, in connection with this very technical subject, and when it is further remembered that this period was one in which the wonderful developments of wireless telegraphy, due to the efforts of Mr. Marconi, were in their most active stage; that Mr. Marconi was engaged in attending to the numerous experiments which were being carried on under his direction, over all Europe and in America and was also necessarily giving his personal attention to the organization of commercial companies to carry on the practical development of his system; and that, as the foremost figure in this new art, his personal services were demanded by many large interests, it is not believed that it can be said that he was negligent in requiring the space of two months to prepare these papers.

In view of this showing, it is not believed that your Honor will hold that in thus delaying for so short a time the forwarding of these papers, Mr. Marconi was guilty of negligence.

It must be remembered that Mr. Marconi had until the 3rd of June to amend his application. We do not, of course, contend that this would justify him in *intentionally* postponing action, but in preparing these papers within two months, Mr. Marconi certainly gave the matter as much attention as a prudent and careful business man would give to his most important business affairs.

[fol. 3664] These papers, which were despatched early in April, did not reach their destination; they were lost in transmission in some manner which has never been, and probably can never be, accounted for.

During the period immediately following the despatch of these papers by Mr. Marconi, when he supposed they were on their way to his attorneys and would arrive in due course, and his attorneys, relying on the information contained in the letter received April 19, 1903, in reply to their letter of March 20, 1903, also supposed that these papers were on their way and would arrive in due course, certainly no one can be blamed for negligence.

The attorneys for Marconi waited for these papers until May 13th, and again wrote to England urging that the papers be despatched immediately.

In the decision of December 2nd, your Honor said:

"The cablegram as to Marconi's illness was after the application was abandoned and thereafter (therefore) it does not appear that the illness had anything to do with the failure to act within the year."

It is believed that the affidavits *now* filed with this request show that Mr. Marconi's illness begun in the middle of April and thus prevented the filing of the amendment within the year.

The letter from the attorneys, of May 13th, was received by Marconi's Wireless Telegraph Company, Limited, on May 22nd. At that time Mr. Marconi was ill in Italy and unable to attend to business, and he did not recover sufficiently to attend to business until the middle of June. In the meantime, or on June 3rd, the year allowed by law, terminated.

[fol. 3665]

It is believed that it has been shown that during this whole year everything had been done to forward the prosecution of this case that could in reason be asked. The case had been under constant consideration by the persons interested in its prosecution. All of these persons were certainly aware of the important interests involved, and were using the greatest care to see that these interests were properly and adequately protected.

The repeated and unexpected postponements of Mr. Marconi's visit to America, caused the postponement of a ion for seven months, but these postponements could not have been anticipated and there was no reason to suppose that the delay would be of any such length.

The fact that Mr. Marconi could not furnish the desired information without consulting his records in London, caused a further unexpected and unavoidable postponement of action.

Notwithstanding all this, papers were prepared which, but for their loss in the mail, would have made it possible to amend the case within the year.

Finally, at the very end of the year, when the loss of the papers was discovered, Mr. Marconi was incapacitated by a serious illness, and it became impossible to make the necessary amendment.

[fol. 3666] Immediately after the expiration of the year, on June 5, 1903, the attorneys for Marconi wrote a further letter to Marconi's Wireless Telegraph Co., Ltd., to ascertain why the necessary papers had not been sent. In reply to this letter they received a cablegram, dated July 3, 1903, saying that Mr. Marconi had been ill and that for this reason the papers had not been sent. The attorneys for Marconi then immediately took steps to protect his rights by preparing a petition, asking your Honor to declare that the case was not abandoned.

This petition was sent to Mr. Thomas E. Robertson, of 605 7th Street, Washington, on July 8th, and the attorneys for Marconi were informed by him that the petition must be accompanied by an amendment. They were, therefore, compelled to await the receipt of the information from Mr. Marconi.

On August 21, 1903, certain papers were received from Mr. Marconi, but these papers were insufficient to enable his attorneys to make the necessary amendment, and they were

compelled to await his arrival in New York, in the latter part of September, 1903. Upon his arrival, he was consulted in regard to this application, and on October 12th the proper amendment and petition were filed.

It will be noticed that the second time Mr. Marconi undertook to prepare these papers, it again required a period of two months. Even at this time, when Mr. Marconi knew that the papers should be furnished immediately, it was impossible for him to prepare them in less time.

[fol. 3667] On December 2nd, your Honor's decision, denying the petition, was rendered, and a copy of this decision was sent to Mr. Marconi by the first steamer leaving New York. Mr. Marconi immediately replied with a statement in regard to his illness during the period from the middle of April to the middle of June, 1903, and instructing his attorneys to ask for a reconsideration of the petition, in view of the additional showing which he could make, and which your Honor had indicated, in the last paragraph of the decision of December 2nd, was necessary.

Mr. Marconi's attorneys, by the next steamer, sent to him an outline of the affidavit desired, and he immediately drew up the necessary affidavit and returned it to his attorneys, by whom it was received on the 15th day of February 1904. The affidavit, together with a supplemental affidavit of Mr. Betts, and a request for reconsideration, were forwarded to Washington on February 20th.

In the prosecution of this application, the failure to file the necessary amendment was undoubtedly caused by a loss of papers in the mail, that is, by an accident beyond the control of the applicant, and unavoidable.

There have been a number of cases in the history of the Patent Office, and even during your Honor's administration, in which failure to file the necessary amendment has been caused directly by an unavoidable accident occurring near the end of the period allowed by law, and in which cases it has been held that the delay was not "unavoidable" within [fol. 3668] the meaning of that term as used in section 4894 of the Revised Statutes.

In each of these cases, however, there has been some period through the year in which the application was deliberately laid aside with the intention of postponing action for some purpose or other, or else, the actions which were taken by the applicant have not been bona fide attempts to further the prosecution of the applications.

In the present case, there has never been any such period of intentional delay, and there has never been taken any action which was not a bona fide attempt to further the prosecution.

We have been unable to find any case which has been held to be abandoned where there has been, during the whole year, a bona fide attempt to amend the application as soon as possible.

It is believed that it has been shown that in this case there has been such a bona fide attempt.

Favorable action on the petition is respectfully asked.

Respectfully submitted,

BETTS, BETTS, SHEFFIELD & BETTS,

Attorneys for Marconi.

Ex parte Guglielmo Marconi.

Apparatus for Wireless Telegraphy.

Petition.

Application filed November 10, 1900, No. 36,010.

Messrs. Betts, Betts, Sheffield & Betts and Mr. T. E. Robertson for applicant.

This is a petition for a reconsideration of the question of abandonment of the above-entitled application.

In the decision dated December 2, 1903, it was held that the application must be regarded as abandoned in the absence of a more complete showing of the reasons for the delay than that included in the affidavits then filed. The present petition is supported by an affidavit of the inventor and by affidavits of one of the principal attorneys and an associate.

It appears that the inventor was traveling during many months immediately after the last office letter, and that it was difficult to communicate with him. By reason of the character of the invention, it was necessary for the attorneys to obtain his advice and assistance in replying to the examiner's action, and since he was constantly expected to come to this country, the attorneys postponed action until his arrival. Various circumstances interfered with his plans to visit this country, and his visit was postponed from [fol. 3671] time to time. When he did arrive, in January, 1903, he was consulted about this application, but found it necessary to refer to his papers in London before giving his instructions. This was five months before the year allowed by law expired. Upon returning to London the inventor prepared the papers, giving his attorneys instructions, and left them with a notary early in April, 1903, to be forwarded, but they were never received by the attorneys. It is not clear what became of them. For two months after April 15, 1903, the inventor was incapacitated for business by illness, and although the attorneys were active in seeking the

information to be used as the basis for a reply to the examiner's action, the inventor was unable to furnish it. Upon his recovery, he again prepared his instructions to his attorneys and forwarded the papers to them, and upon a second trip to this country gave them oral advice. Responsive action was then taken in the case.

Under all of the circumstances, it must be held that reasonable diligence was exercised in preparing a response to the last office action and that the delay was unavoidable.

The petition is granted.

F. I. ALLEN,
Commissioner.

Please find below a communication from the Examiner in charge of [the]* your application [of]* 36,010, filed November 10, 1900, for Apparatus for Wireless Telegraphy.

F. I. ALLEN,
THOMAS EWING,
Commissioner of Patents.

[*Words and figures enclosed in brackets erased in copy.]

This application having been revived by the Commissioner, applicant's amendment of October 12, 1903, has been entered as corrected by his amendment of October 24, 1903. The following action is taken:

The claims are all allowed except claims 4, 5, 6 and 7, which are rejected on the patent to Stone, 714,756, December 2, 1902, application filed February 8, 1900.

Stone shows in Fig. 5 a transformer M whose secondary L_2 is connected to an open circuit including a radiating conductor V at one end and a capacity E at the other and whose primary L_1 is connected to a condenser circuit discharging through a spark gap, viz., the circuit C s L_1 L. These circuits are in "electrical resonance with each other",—see lines 16-20, page 2. It is not stated how the elevated conductor is given a natural period equal to that of the oscillations impressed upon it but it is well-known by all skilled in this art that this may be accomplished by adjusting the length of the elevated conductor, thereby adjusting the distributed capacity and the distributed inductance of the same until the natural period of such conductor is equal to the [fol. 3673] natural period of the condenser circuit C sL_1 L. =36,010.

[fol. 3673] When this is done "the frequency impressed upon the elevated conductor" is "the same as the natural period or fundamental of such conductor", to quote from the Stone patent.

Applicant discloses another means whereby the same result may be effected, viz., by including a "variable inductance" in the elevated conductor. All claims which include this element are considered allowable over the Stone patent.

In regard to claim 7 it may be said that Stone states that the operator at each station may at will adjust his apparatus in such way as to place himself in communication with any other station (page 4, lines 28-36) and that he also states that this result may be effected by making the coil L of the condenser circuit adjustable (page 6, lines 76-81). Inasmuch as the period of an oscillating circuit depends upon the capacity of the condenser in the same way that it depends upon the inductance of the coil, it is held that it is not patentable to make the condenser e of applicant's oscillating circuit adjustable for the same purpose as Stone makes the coil L of his oscillating circuit adjustable.

Claims 4, 5, 6 and 7 will be allowed if amended by inserting the words *a variable inductance and* after the word "including" in line 3 of each claim.

In claim 8, line 6, the words "said circuit" are repeated and should be canceled.

CAMPBELL,
Examiner, Division XVI.

Amendment

New York,
May 28, 1904.

Hon. Commissioner of Patents,
Washington, D. C.

Sir:

We authorize and request the following amendment of the Specification of this Application:

In line 10 of page 1, after "tions," insert "or electric waves."

In line 12, same page, after "oscillations", insert "or electric waves."

In line 13, same page, before "selected", insert "one."

In line 1 of page 2, cancel "only."

In line 19 of same page, insert before "a spark producer", the words

F'. "a producer of Hertzian oscillations or electric waves shown in the form of."

In the same line, insert "an" before "induction coil."

Same page, at the end of line 24, insert "a device responsive to electric waves, such as."

In line 13 of page 3, change "Ruhmkorff" to "induction."

In line 17, same page, insert before "oscillation producer," the words electric wave or."

In lines 23 and 24 of same page, substitute "induction" for "Ruhmkorff."

[fol. 3675] After the end of line 28 of same page, insert

F². "It is obvious that instead of the induction coil and associated parts for producing the electric waves or oscillations, I may use any other proper means for producing such waves or oscillations, such, for instance, as a generator of alternating electric currents."

In line 15 of page 4, substitute "induction" for "Ruhmkorff."

In line 23, same page, after "radiated," insert "in the form of electric waves."

5

Exr. In line 10 of page [4]*, ^ before "oscillations", Insert "waves or."

Before the paragraph beginning in line 11 of page 5, insert a paragraph as follows:

F³. "As a responder to electric waves, I may use at the receiving station any of the now well known forms of such devices such as those which depend for their action on the reduction of the resistance of a metallic microphone by the action of electric waves, or 'coherers', one form of which is disclosed in my patent No. 586,193; or I may employ one which depends for its action on the increase of the resistance of the device under the influence of the electric waves, or 'anti-coherers', such as described by Branly in 'La Lumiere Electrique' of June 13, 1891; or I may use those which depend upon the action of an electric

[*Words and figures enclosed in brackets erased in copy.]

wave as a magnetizing or demagnetizing agency, such as I have disclosed in my application No. 132,974, filed November 28, 1902; or I may use various other well known devices such as the electrolytic, electro-[fol. 3676] thermal, electromagnetic or electro-dynamic responders."

In lines 22, 23 and 25 of page 5, cancel "pending application, serial No. — filed February 21, 1901, for "and insert after "United States," "No. 676,332," unless this has *already been done*.

In line 15 of page 6, change "detector" to "wave responsive device."

On the same page, cancel the paragraph beginning at line 16 and ending in line 23, and substitute therefor the following:

F⁴. "The capacity and self-induction of the four circuits—i. e., the primary and secondary circuits at the transmitting station and the primary and secondary circuits at any one of the receiving stations, in a communicating system—are each and all to be so independently adjusted as to make the product of the self-induction multiplied by the capacity, the same in each case, or multiples of each other, that is to say, the electrical time periods of the four circuits are to be the same, or octaves of each other."

On page 7, line 7, cancel "the" and substitute "any or all of the four."

Cancel claims 4 and 5 and substitute therefor the following:

F⁵. "4. In a system of syntonic wireless telegraphy, a circuit so arranged as to form a persistent oscillator, a circuit so formed as to constitute a good radiator in inductive relation thereto, means for inducing in the oscillator circuit electric undulations of a predetermined period, and means for attuning the natural [fol. 3677] period of vibration of each of said circuits to the period of the undulations so induced.

F⁶. 5. An element of an apparatus employed in a system of telegraphy by electric waves or oscillations of high frequency, comprising a conductor elevated at

one end and connected to capacity at the other end, said conductor including a variable inductance and an element having appreciable capacity."

In claim 6, line 8, insert "each of" before "the two circuits."

Cancel claim 7 and substitute therefor:

F[6]. "7. An element of an apparatus employed in a system of telegraphy by electric waves or oscillations of high frequency, comprising an open circuit so arranged as to constitute a radiator of such waves or oscillations, and means for varying at will the natural period of vibration of the said circuit."

In claim 11, lines 5 and 6, cancel "sparking device" and substitute "producer of electric waves of high frequency."

In claim 12, line 5, cancel "sparking device" and substitute "producer of electric waves of high frequency."

In claim 19, line 9, cancel "imperfect contact" and substitute "wave responsive."

In claim 20, line 5, cancel "oscillations" and substitute "electric waves."

[fol. 3678] Remarks

The claims now presented, all include an elevated conductor, or a circuit which is a good radiator of electric waves or oscillations, and means for adjusting the tune of such elevated conductor or radiating circuit. It is believed that the Examiner recognizes the fact that the Stone Patent does not show such an arrangement, and an early allowance is requested.

Respectfully submitted,

Guglielmo Marconi, Assor.

c. T. S. Robertson,

City

SIR:—Your APPLICATION for a patent for an IMPROVEMENT IN

Apparatus for Wireless Telegraphy

Filed Nov. 10, 1900, has been examined and ALLOWED.

The final fee, **Twenty Dollars**, must be paid, and the Letters Patent bear date as of a day not later than SIX MONTHS from the time of this present notice of allowance.

If the final fee is not paid upon that period the patent will be withheld, and your only relief will be by a renewal of the application, with additional fees, under the provisions of Section 4897, Revised Statutes. The Office aims to deliver patents upon the day of their date, and on which their term begins to run; but to do this properly applicants will be expected to pay their final fees at least TWENTY DAYS prior to the conclusion of the six months allowed them by law. The printing, photolithographing, and engrossing of the several patent parts, preparatory to final signing and sealing, will consume the intervening time, and such work will not be done until after payment of the necessary fees.

When you send the final fee you will also send, DISTINCTLY AND PLAINLY WRITTEN, the name of the INVENTOR, and TITLE OF INVENTION AS ABOVE GIVEN, DATE OF ALLOWANCE (which is the date of this circular), DATE OF FILING, and, if assigned, the NAMES OF THE ASSIGNEES.

If you desire to have the patent issue to ASSIGNEES, an assignment containing a REQUEST to that effect, together with the FEE for recording the same, must be filed in this Office on or before the date of payment of final fee.

After issue of the patent uncertified copies of the drawings and specifications may be purchased at the price of 5 cents each. The money should accompany the order. Postage stamps will not be received.

Respectfully,

F. I. Allen,

Commissioner of Patents.

After allowance, and prior to payment of the final fee, applicants should carefully scrutinize the description to see that their statements and language are correct, as mistakes not incurred through the fault of the office, and not affording legal grounds for reissues, will not be corrected after the delivery of the letters patent to the patentee or his agent.

IN REMITTING THE FINAL FEE GIVE THE SERIAL NUMBER AT THE HEAD OF THIS NOTICE.

If payment is made by check or draft, the credit allowed is subject to the collection of the same.

$ 20- RECEIVED

UNITED STATES PATENT OFFICE.

GUGLIELMO MARCONI, OF LONDON, ENGLAND, ASSIGNOR TO MARCONI'S WIRELESS TELEGRAPH COMPANY, LIMITED, OF LONDON, ENGLAND.

APPARATUS FOR WIRELESS TELEGRAPHY.

SPECIFICATION forming part of Letters Patent No. 763,772, dated June 28, 1904.

Application filed November 10, 1900. Serial No. 36,010. (No model.)

To all whom it may concern:

Be it known that I, GUGLIELMO MARCONI, electrician, a subject of the King of Italy, residing and having a post-office address at 18 Finch Lane, Threadneedle street, in the city of London, England, have invented certain new and useful Improvements in Apparatus for Wireless Telegraphy, of which the following is a specification.

My invention relates to apparatus for communicating electrical signals without wires and by means of Hertz oscillations or electric waves; and the object of the invention is to increase the efficiency of the system and to provide new and simple means whereby oscillations or electric waves from a transmitting-station may be localized when desired at any one selected receiving station or stations out of a group of several receiving-stations.

In my prior United States patent No. 586,193 (Reissue No. 11,913, dated June 4, 1901) I have shown and described the combination at a transmitting-station of an oscillation-producer, such as an induction-coil, having one end of its secondary coil connected to one contact of a spark-producer and to the earth and having the other end of the said secondary connected to the opposite contact of the spark-producer and to a vertical wire or elevated plate, and I have further shown at a receiving-station an imperfect contact connected in circuit with a vertical receiving-wire and with the earth. According to the present invention the system includes at the transmitting-station the combination, with an oscillation-transformer of a kind suitable for the transformation of very rapidly alternating currents, of a persistent oscillator, and a good radiator, one coil of said transformer being connected between the aerial wire or plate and the connection thereof to earth, while the other coil of the transformer is connected in circuit with a condenser, a producer of Hertzian oscillations or electric waves shown in the form of a spark-producer, and an induction-coil (constituting the persistent oscillator) controlled by a signaling instrument. The complete system also includes at a receiving-station an oscillation-transformer one coil whereof is included between the aerial receiving-wire and earth, constituting a good absorber of electrical oscillations, while a device responsive to electric waves, such as an imperfect contact or a device for operating the same, is included in a circuit with the other coil of said transformer. The system also requires as essential elements thereof the inclusion in the lines (at both stations) from the aerial conductor to the earth of variable inductances and the use at both stations of means for varying or adjusting the inductance of the two circuits at each station to accord with each other. By this arrangement of apparatus I am able to secure a perfect "tuning" of the apparatus at a transmitting-station and at one or more of a number of receiving-stations.

Referring to the accompanying drawings, Figure 1 indicates diagrammatically the arrangement of apparatus at a transmitting-station. Fig. 2 indicates diagrammatically the arrangement of apparatus at a receiving-station. Figs. 3 and 4 are views, plan and side, of the preferred form of transformer at the transmitting-station. Figs. 5, 6, 7, and 8 are diagrammatic views of forms of transformers at the receiving-station.

The transmitting-station is provided under my present invention with a source *a* of current electrically connected in circuit with the primary of an induction-coil *c* and with a circuit-closing key *b* or otherwise controlled by a signaling instrument. In the secondary circuit of said induction-coil the spherical terminals or other contacts of a spark-producer or other electric-wave or oscillation producer are included with a shunt therefrom, in which shunt is included the primary coil *d* of an oscillation-transformer, such as *d'*. A condenser *e*, preferably one provided with two telescoping metallic tubes separated by a dielectric and arranged to readily vary the capacity by being slid upon each other, is included in one connection from the induction-coil to the transformer-winding *d*. The secondary coil *d'* of the transformer is connected (at one end) to the earth E and at its other end to a vertical wire A or an elevated plate *f*.

It is obvious that instead of the induction-

coil and associated parts for producing the electric waves or oscillations I may use any other proper means for producing such waves or oscillations—such, for instance, as a generator of alternating electric currents.

The illustrated arrangement of parts at a transmitting-station enables much more energy to be imparted to the radiator *f*, the approximately closed circuit of the primary being a good conserver and the open circuit of the secondary being a good radiator of wave energy. My experiments have demonstrated that the best results are obtained at the transmitting-station when I use a persistent oscillator—an electrical circuit of such a character that if electromotive force is suddenly applied to it and the current then cut off electrical oscillations are set up in the circuit which persist or are maintained for a long time in the primary circuit and use a good radiator—*i. e.*, an electrical circuit which very quickly imparts the energy of electrical oscillations to the surrounding ether in the form of waves—in the secondary circuit.

In operation the signaling-key *b* is pressed, and this closes the primary of the induction-coil. Current then rushes through the transformer-circuit and the condenser *c* is charged and subsequently discharges through the spark-gap. If the capacity, the inductance, and the resistance of the circuit are of suitable values, the discharge is oscillatory, with the result that alternating currents of high frequency pass through the primary of the transformer and induce similar oscillations in the secondary, these oscillations being rapidly radiated in the form of electric waves by the elevated conductor.

For the best results and in order to effect the selection of the station or stations whereat the transmitted oscillations are to be localized I include in the open secondary circuit of the transformer, and preferably between the radiator *f* and the secondary coil *d*, an inductance-coil *g*, Fig. 1, having numerous coils, and the connection is such that a greater or less number of turns of the coil can be put in use, the proper number being ascertained by experiment.

At the receiving-stations employing my present invention I prefer to use a receiver such as those described in my several United States Patents, Nos. 586,193, 627,650, 647,007, 647,008, 647,009, and 668,315, capable of being affected by electrical waves or oscillations of high frequency.

As a responder to electric waves I may use at the receiving-station any of the now well-known forms of such devices, such as those which depend for their action on the reduction of the resistance of a metallic microphone by the action of electric waves or "coherers," one form of which is disclosed in my Patent No. 586,193, or I may employ one which depends for its action on the increase of the resistance of the device under the influence of the electric waves or "anticoherers," such as described by Branly in *La Lumiere Electrique* of June 13, 1891, or I may use those which depend upon the action of an electric wave as a magnetizing or demagnetizing agency, such as I have disclosed in my application Serial No. 132,974, filed November 28, 1902, or I may use various other well-known devices, such as the electrolytic, electrothermal, electromagnetic, or electrodynamic responders.

Referring to Fig. 2, *f'* indicates a plate or cylinder (not essential at either transmitter or receiver) at the upper end of an elevated conductor A, which is connected to the primary coil *j'* of a transformer or induction-coil and thence to earth E. In a shunt around said primary *j'* I usually place a condenser *h*, preferably similar in construction and operation to the condenser *c*. An inductance-coil *g'* of variable inductance is interposed in the primary circuit of the transformer, being preferably located between the cylinder *f'* and the coil *j'*, and the inductance of said coil may be adjusted in accordance with the method described by me in my Letters Patent of the United States No. 676,332 to harmonize with the inductance of coil *g* at the transmitting-station, Fig. 1 of the accompanying drawings, or with that of the coil or coils at one or more of the transmitting-stations included in the communicating system.

The secondary coil *j''* of the transformer is wound in two parts, preferably as described in my United States Letters Patent No. 668,315, dated February 19, 1901, and the outer ends of said coil are connected in certain cases through one or more interposed inductance-coils *g''*, preferably of variable inductance, with the terminals of a coherer T or other detector of electrical oscillations. The inner ends of the split secondary coil are connected to the plates of a condenser *j''*. A condenser *h'* is sometimes included in a shunt around the detector T. B is a battery, and R a relay connected to the condenser *j''* and controlling a telegraphing instrument or a printing device. *c'* and *c''* are choking-coils preventing oscillations from the secondary *j''* running into the battery-circuit and thereby confining them to the wave-responsive device.

The capacity and self-induction of the four circuits—*i. e.*, the primary and secondary circuits at the transmitting-station and the primary and secondary circuits at any one of the receiving-stations in a communicating system—are each and all to be so independently adjusted as to make the product of the self-induction multiplied by the capacity the same in each case or multiples of each other—that is to say, the electrical time periods of the four circuits are to be the same or octaves of each other.

In employing this invention to localize the

transmission of intelligence at one of several receiving-stations the time period of the circuits at each of the receiving-stations is so arranged as to be different from those of the other stations. If the time periods of the circuits of the transmitting-station are varied until they are in resonance with those of one of the receiving-stations, that one alone of all of the receiving-stations will respond, provided that the distance between the transmitting and receiving stations is not too small.

The adjustment of the self-induction and capacity of any or all of the four circuits can be made in any convenient manner and employing various arrangements of apparatus, those shown and described herein being preferred. In practice I have found the following preferred details of arrangements of apparatus to work well: The aerial conductors A at all stations and the conductor for the transformer-windings at the receiving-stations are composed of seven strands of copper wire .889 millimeters in diameter. The transformer at the transmitting-station may be of any of the following forms:

1. Around a block or core d', preferably a square block—say .17 meters wide—of insulating material is wound a primary coil d in length .946 meters, while the secondary d' consists of two turns or squares, one lying on each side of the primary. (See Figs. 3 and 4.) The insulation of both primary and secondary consists of 1.25 millimeters of rubber and one millimeter of jute, making a total thickness of 2.25 millimeters.

2. A transformer in all essential respects similar to 1, but with a primary of 1.93 meters and the core or block on which both primary and secondary are wound, is .3048 meters wide.

3. A transformer having a cylindrical core 10.16 centimeters in diameter and with a primary having ten turns wound thereon; over this, but separated by two millimeters of paper or other insulant, the secondary, also of ten turns.

Various forms of transformers, &c., which may be employed by me are described in my British Patent No. 7,777 of 1900.

The inductance-coils g and g' are preferably of copper wire 6.25 millimeters in diameter, wound on a cylinder 10.64 centimeters in diameter, with an interval of 2.28 millimeters between adjacent turns. The inductance-coils g^3 at the receiving-station are preferably of silk-covered copper wire .19 millimeter diameter wound upon cylinders 3.7 centimeters in diameter.

Various forms of induction-coils j'' j^3 may be used. Figs. 5, 6, 7, and 8 show details of different forms. The figures show diagrammatically greatly-enlarged longitudinal sections not strictly to scale. Instead of showing the section of each coil or layer of wire as a longitudinal row of dots or small circles, as it would actually appear, it is for simplicity shown as a continuous longitudinal straight line.

Referring to Fig. 5, the primary j'' preferably consists of 3.046 meters of silk-covered copper wire, say, and seventy-one millimeters in diameter wound in one layer on a core of ebonite or other insulating material 2.9 centimeters in diameter. Insulating material is wound over and on each side of this, so as to make a cylindrical core, say, 3.13 centimeters in diameter, on which is wound the secondary, each half of which consists of 6.4 meters of silk-covered copper wire .19 millimeter in diameter joined to 13.41 meters of silk-covered copper wire .37 millimeter in diameters wound in the same sense as the primary, the thinner wire being over the primary and the thicker being beyond the ends thereof.

The form of induction-coil shown in Fig. 6 has a primary of one hundred turns of copper wire .037 centimeters in diameter wound on a core j (2.9 centimeters in diameter) with a single silk covering and coated with paraffin-wax. The secondary j^3 is of copper wire .019 in diameter, insulated with a single silk covering, and is wound over the primary, commencing in the middle and in the same way as the primary. Each half of the secondary is in layers of the following number of turns: first layer, seventy-seven turns; second layer, forty-nine turns; third layer, forty-six turns; fourth layer, forty-three turns; fifth layer, forty turns; sixth layer, thirty-seven turns; seventh layer, thirty-four turns; eighth layer, thirty-one turns; ninth layer, twenty-eight turns; tenth layer, twenty-five turns; eleventh layer, twenty-two turns; twelfth layer, nineteen turns; thirteenth layer, sixteen turns; fourteenth layer, thirteen turns; fifteenth layer, ten turns; sixteenth layer, seven turns; and seventeenth layer, three turns, making five-hundred turns in all.

A third form of induction-coil (shown in Fig. 7) has a primary of 3.048 meters of silk-covered copper wire .19 millimeter in diameter and a secondary of 30.48 meters of silk-covered copper wire .1 millimeter in diameter wound in one layer on a core four centimeters in diameter, the primary being in one layer outside of the secondary.

The fourth form of induction-coil is shown in Fig. 8. Its primary consists of 3.048 meters of silk-covered copper wire .37 millimeter in diameter wound on a core 2.9 centimeters in diameter and inserted in a tube j^4 of four centimeters external diameter, on which is wound the secondary of 27.432 meters of silk-covered copper wire .12 millimeter in diameter, the break at the middle of the secondary being over the middle of the primary.

Other forms of transformers which may be employed by me are described and claimed in my British Patent No. 7,777 of 1900.

The following tables give preferred adjustments, those details opposite any tune in the transmitting-station table being of course used in connection with those opposite the same tune in the receiving-station table:

Transmitting-Station.

Tune	Aerial conductor	Transformer *d d'*	Inductance number of turns of *g* included	Capacity microfarads *e*	Length of spark in millimeters.
No. 1	38.578 meters of cable	No. 1.	None.	.0[illegible]984	3
No. 2	do	No. 1.	45	.016888	4
No. 3	do	No. 2.	None.	.004112	3
No. 4	do	No. 2.	100	.010849	4
No. 5	Zinc cylinder 9.144 meters long, 1.524 meters in diameter, and hoisted 8.048 meters above ground.	No. 2.	None.	.021600	12.5
No. 6	30.48 meters of cable.	No. 2.	None.	.000873	4

Receiving-Station.

Tune	Induction-coil.	Capacity in microfarads of—		Inductance introduced in—	
		A.	A'	*g'*. Number of turns.	*g*³.
No. 1.	No. 1.	Omitted.	Omitted.	None.	None.
No. 2.	No. 1.	Omitted.	.0[illegible]04	45	None.
No. 3.	No. 2.	.0046	Omitted.	Up to 21 may be inserted.	None.
No. 4.	No. 2.	.0046	Omitted.	100	2 coils of 15.24 meters at each end of secondary.
No. 5.	No. 3.	Omitted.	Omitted.	None.	None.
No. 6.	No. 4.	Omitted.	Omitted.	None.	None.

It will be observed that both the transmitter and the receiver are the same for tunes 1 and 2 and that when the capacity of the condenser *e* is varied the two stations can be brought into tune by including forty-five turns of each of the coils *g g'* and by introducing a condenser *k* of small capacity in parallel with the coherer T. Similarly the transmitter and receiver are the same for tunes 3 and 4, and when the capacity of *e* is varied the stations are tuned by including one hundred turns of each of the coils *g* and *g'* and by also including the coils g^3.

While I have herein shown and described details of construction and of arrangement found by me to be useful, yet I do not wish to be understood as confining my claims thereto. Obviously modifications which are within my invention will readily suggest themselves to skilled persons.

What I claim is

1. At a station employed in a wireless-telegraph system, a signaling instrument comprising an induction-coil, the secondary circuit of which includes a condenser discharging through a means which automatically causes oscillations of the desired frequency; an open circuit electrically connected with the oscillation-producer aforesaid and a variable inductance included in the open circuit, substantially as and for the purpose described.

2. At a station employed in a wireless-telegraph system, an oscillation-receiving conductor, a variable inductance connected with said conductor; a wave-responsive device electrically connected with said conductor and in circuit with a condenser, substantially as and for the purpose described.

3. At a station employed in a wireless-telegraph system, a signaling instrument comprising an induction-coil, the secondary circuit of which includes a condenser discharging through a means which automatically causes oscillations of the desired frequency, and the

primary circuit of which includes a generator; means for varying the primary circuit; an open circuit electrically connected with the oscillation-producer aforesaid, and a variable inductance included in the open circuit, substantially as and for the purpose described.

4. In a system of syntonic wireless telegraphy, a circuit so arranged as to form a persistent oscillator, a circuit so formed as to constitute a good radiator in inductive relation thereto, means for inducing in the oscillator-circuit electric undulations of a predetermined period, and means for attuning the natural period of vibration of each of said circuits to the period of the undulations so induced.

5. An element of an apparatus employed in a system of telegraphy by electric waves or oscillations of high frequency, comprising a conductor elevated at one end and connected to capacity at the other end, said conductor including a variable inductance and an element having appreciable capacity.

6. At a transmitting-station employed in a wireless-telegraph system, the combination of a transformer whose secondary is connected to an open circuit including a radiating-conductor at one end and capacity at the other end, and whose primary is connected to a condenser-circuit discharging through a means which automatically causes oscillations of the desired frequency, and means for adjusting the oscillation period of each of the two circuits connected with the transformer to bring them into accord with each other, substantially as described.

7. An element of an apparatus employed in a system of telegraphy by electric waves or oscillations of high frequency, comprising an open circuit so arranged as to constitute a radiator of such waves or oscillations, and means for varying at will the natural period of vibration of the said circuit.

8. At a transmitting-station employed in a wireless-telegraph system, the combination of a transformer whose secondary is connected to an open circuit including a radiating-conductor at one end and capacity at the other end, a variable inductance being included in said circuit, and whose primary is connected to a condenser-circuit discharging through a means which automatically causes oscillations of the desired frequency, substantially as described.

9. At a transmitting-station employed in a wireless-telegraph system, the combination of a transformer whose secondary is connected to an open circuit including a radiating-conductor at one end and capacity at the other end, a variable inductance being included in said circuit, and whose primary is connected in series with an adjustable condenser and with a means which automatically causes oscillations of the desired frequency, substantially as described.

10. A system of wireless telegraphy, in which the transmitting-station and the receiving-station each contains an oscillation transformer, one circuit of which is an open circuit and the other a closed circuit, the two circuits at each station being in electrical resonance with each other and in electrical resonance with the circuits at the other station, substantially as described.

11. In apparatus for communicating electrical signals, the combination, with an oscillation-transformer, at a transmitting-station, of an induction-coil; an electric circuit containing the secondary of said coil, a condenser and the primary coil of the oscillation-transformer; a producer of electric waves of high frequency electrically connected with the secondary of the induction-coil: a signaling instrument in circuit with the primary of the induction-coil; the secondary coil of the oscillation-transformer electrically connected, at one end to capacity and, at the other end, to an inductance, and an aerial conductor connected to the inductance, substantially as and for the purpose described.

12. In apparatus for communicating electrical signals, the combination, with an oscillation-transformer, at a transmitting-station, of an induction-coil; an electric circuit containing the secondary of the said coil, a condenser and the primary coil of the oscillation-transformer; a producer of electric waves of high frequency connected with the secondary of the induction-coil; a signaling instrument in circuit with the primary of the induction-coil; the secondary coil of the oscillation-transformer electrically connected, at one end, to capacity and, at the other end, to a variable inductance, and an aerial conductor connected to the variable inductance, substantially as and for the purpose described.

13. At a receiving-station employed in a wireless-telegraph system, the combination of an oscillation-transformer, an open circuit connected with one coil of said transformer, said circuit including an oscillation-receiving conductor at one end and capacity at the other end, a variable inductance being included in said circuit, a wave-responsive device electrically connected with the other winding of the oscillation-transformer, and a condenser in circuit with the wave-responsive device, substantially as described.

14. At a receiving-station employed in a wireless-telegraph system, the combination of an oscillation-transformer, an open circuit connected with one coil of said transformer, said circuit including an oscillation-receiving conductor at one end and capacity at the other end, a wave-responsive device electrically connected with the other winding of the oscillation-transformer, and means for adjusting the two transformer-circuits in electrical resonance with each other, substantially as described.

15. At a receiving-station employed in a wireless-telegraph system, the combination of an oscillation-transformer, an open circuit connected with one coil of said transformer, said circuit including an oscillation-receiving conductor at one end and capacity at the other end, a condenser located in said circuit between the coil and the capacity, a wave-responsive device electrically connected with the other winding of the oscillation-transformer, and means for adjusting the two transformer-circuits in electrical resonance with each other, substantially as described.

16. At a receiving-station employed in a wireless-telegraph system, the combination of an oscillation-transformer, an open circuit connected with one coil of said transformer, said circuit including an oscillation-receiving conductor at one end and capacity at the other end, an adjustable condenser in a shunt connected with the open circuit and around said transformer-coil, a wave-responsive device electrically connected with the other coil of the oscillation-transformer, and means for adjusting the two transformer-circuits in electrical resonance with each other, substantially as described.

17. At a receiving-station employed in a wireless-telegraph system, the combination of an oscillation-transformer, an open circuit connected with one coil of said transformer, said circuit including an oscillation-receiving conductor at one end and capacity at the other end, a wave-responsive device electrically connected with the other winding of the oscillation-transformer, and means included in each of said transformer-circuits, for adjusting said circuits in electrical resonance with each other, substantially as described.

18. At a receiving-station employed in a wireless-telegraph system, the combination of an oscillation-transformer, an open circuit connected with one coil of said transformer, said circuit including an oscillation-receiving conductor at one end and capacity at the other end, a variable inductance being included in said open circuit, a wave-responsive device electrically connected with the other winding of the oscillation-transformer, and a variable inductance included in circuit with the wave-responsive device, substantially as described.

19. In a system of wireless telegraphy, the combination at a receiving-station, of an oscillation-transformer; an open circuit comprising, in part, an aerial conductor connected with one end of the primary coil of the oscillation-transformer; a connection from the other end of said coil to capacity; a variable inductance in said open circuit; and electrical connections from the secondary coil of the oscillation-transformer to a receiving instrument, battery, condenser, wave-responsive device and a variable inductance, substantially as and for the purpose described.

20. In a system of wireless telegraphy, a transmitting-station containing an oscillation-transformer, the primary of which is connected to a condenser-circuit discharging through a spark-gap which automatically causes electric waves of the desired frequency, the secondary of said transformer connected to an open circuit including a radiating-conductor, and with a capacity and a coil for charging the condenser aforesaid; a receiving-station containing an oscillation-transformer, the primary of which is connected with an oscillation-receiving conductor and with a capacity, a wave-responsive device connected with the secondary of said transformer, and a receiving instrument connected with the wave-responsive device, all in combination with means for bringing the four transformer-circuits, two at each station, into electrical resonance with each other, substantially as described.

UNITED STATES PATENT OFFICE.

GUGLIELMO MARCONI, OF LONDON, ENGLAND, ASSIGNOR TO THE WIRELESS TELEGRAPH AND SIGNAL COMPANY, LIMITED, OF SAME PLACE.

APPARATUS EMPLOYED IN WIRELESS TELEGRAPHY.

SPECIFICATION forming part of Letters Patent No. 627,650, dated June 27, 1899.

Application filed January 5, 1899. Serial No. 701,251. (No model.)

To all whom it may concern:

Be it known that I, GUGLIELMO MARCONI, electrician, a subject of the King of Italy, residing at 28 Mark Lane, in the city of London, England, have invented certain new and useful Improvements in Apparatus Employed in Wireless Telegraphy, of which the following is a specification.

In the specification of a former patent granted to me, No. 586,193, I described a receiver in which the ends of an imperfect contact in a local circuit were connected one to earth and the other to an insulated conductor.

According to this invention the conductor is no longer insulated, but is connected to a capacity, which may be the earth, through the primary of an induction-coil, while the ends of the imperfect contact are connected to the ends of the secondary one of the connections, being through a condenser.

The induction-coil preferably consists of a few turns of insulated wire. Over or under this first winding, which constitutes the primary, is wound a secondary winding, which constitutes the secondary.

In order to obtain the best effects, it is essential that the induction-coil should be of very thin wire. It is desirable that the primary and secondary windings of the coil should be close to each other and that the windings of each should be in a single layer. It is desirable that the induction-coil should be in tune or syntony with the electrical oscillation transmitted, the most appropriate number of turns and most appropriate thickness of wire varying with the length of wave of the oscillation transmitted.

The capacity of the condenser on the connection between the imperfect contact and the secondary of the coil should be varied (in order to obtain best effects) if the length of wave is varied.

It is desirable that the conductor connected should offer a large surface, and therefore the use of such materials as broad wire-netting in lieu of wire is desirable. It is also desirable to employ thick conductors or netting or its equivalents at the transmitting end. The introduction of the coil in the conductor not only improves the signals, but also prevents to a great extent any interference due to atmospheric influences, as any atmospheric electricity collected by the aerial conductor escapes to earth through the primary of the coil, thus preventing a charge from accumulating and discharging itself through the imperfect contact. Any stray interference can be further minimized by substituting a suitable capacity for the earth.

I have used a condenser of about one-fourth microfarad capacity for the above purpose.

Figure 1 is a diagram of the arrangement I prefer. Fig. 2 shows a modification. Fig. 3 shows the induction-coil.

In Fig. 1, A is a long conductor suspended in the air by insulators, and E is a connection to earth or other suitable capacity. B is a local battery, and R is a relay working a signaling or other instrument. p is the primary of the induction-coil or transformer, which is inserted between A and E. k is a condenser placed across the sensitive imperfect contact and the secondary winding of the induction-coil or transformer. c c^2 are choking-coils, their object being to prevent the oscillations generated in the winding p^2 from running into the battery connections at b and d, which would weaken the effect of the oscillations on the sensitive imperfect contact T.

Fig. 2 shows a somewhat similar arrangement, which, however, does not give such good results as Fig. 1. In this case the condenser k is omitted.

I have obtained good results by employing an induction-coil or transformer constructed as follows: The primary p of the said induction-coil or transformer is wound on a glass tube f about .635 centimeter in diameter. The said primary winding consists of two parallel windings of two hundred turns each of copper wire .012 centimeter in diameter insulated by a single covering of silk. The resistance of these two windings in parallel is about 3.1 ohms. The secondary winding p^2 of the induction-coil or transformer consists of about eight hundred turns of a similar but thinner wire .005 centimeter in di-

ameter wound over or under the primary winding. The resistance of the secondary winding is about one hundred and forty ohms.

The condenser K, which I preferably use, is composed of six tin-foil or copper plates connected to each terminal, each plate being five centimeters by three centimeters, the plates being insulated by paraffined paper .017 centimeter thick.

When using the above-described induction-coil or transformer, I employ as insulated conductor at each station a conductor formed of seven strands of about one-millimeter-diameter copper wire one hundred and forty feet long, the top of the conductor being one hundred and twenty feet from the ground. In some cases I use in lieu of the above-described conductor a galvanized-iron netting about two feet broad and one hundred and thirty feet long, the top of the netting being about one hundred and ten feet above the ground. In the latter case I obtain good results when using an induction-coil or transformer constituted as follows: secondary winding of three hundred and seventy-five turns of copper wire .005 centimeter in diameter insulated with one covering of silk, and wound on a glass tube .777 centimeter in diameter. Over this is wound the primary winding of one hundred and seventy-five turns of a similar wire .012 centimeter in diameter. The resistance of the primary winding is about 7.1 ohms and that of the secondary about 79 ohms.

What I claim is—

1. In a receiver for electrical oscillations, the combination of an imperfect electrical contact, a local circuit through it, an induction-coil, a capacity, a conductor connected to one end of the primary of the coil, a connection between the other end and the capacity, connections between the ends of the imperfect contact and the ends of the secondary of the coil and a condenser in one of the latter connections.

2. In a receiver for electrical oscillations, the combination of an imperfect electrical contact, a local circuit through it, a local battery and relay included in the local circuit, choking-coils respectively included in said circuit between the terminals of the imperfect electrical contact and the battery and relay, an induction-coil, a capacity, a conductor connected to one end of the primary of the coil, a connection between the other end and the capacity, connections between the ends of the imperfect contact and the ends of the secondary of the coil, and a condenser in one of the latter connections.

3. In a receiver for electrical oscillations, the combination of an imperfect electrical contact, a local circuit through it, an induction-coil, the primary and secondary of which consist of a single layer only, a capacity, a conductor connected to one end of the primary of the coil, a connection between the other end and the capacity and connections between the ends of the imperfect contact and the ends of the secondary of the coil.

4. In a receiver for electrical oscillations, the combination of an imperfect electrical contact, a local circuit through it, an induction-coil, the primary and secondary of which consist of a single layer only, a capacity, a conductor connected to one end of the primary of the coil, a connection between the other end and the capacity and connections between the ends of the imperfect contact, the ends of the secondary of the coil and a condenser in one of the latter connections.

5. In a receiver for electrical oscillations, the combination of an imperfect electrical contact, a local circuit through it, an induction-coil, the primary and secondary of which consist of a single layer only, and in which the primary consists of a number of parallel wires connected at their ends, a capacity, a conductor connected to one end of the primary of the coil, a connection between the other end and the capacity and connections between the ends of the imperfect contact and the ends of the secondary of the coil.

6. In a receiver for electrical oscillations, the combination of an imperfect electrical contact, a local circuit through it, an induction-coil, the primary and secondary of which consist of a single layer only, and in which the primary consists of a number of parallel wires connected at their ends, a capacity, a conductor connected to one end of the primary of the coil, a connection between the other end and the capacity and connections between the ends of the imperfect contact, the ends of the secondary of the coil and a condenser in one of the latter connections.

7. In a receiver for electrical oscillations, the combination of an imperfect electrical contact, a local circuit through it, an induction-coil, the primary and secondary of which are both of wire not exceeding one-fiftieth of a centimeter in diameter, a capacity, a conductor connected to one end of the primary of the coil, a connection between the other end and the capacity and connections between the ends of the imperfect contact and the ends of the secondary of the coil.

8. In a receiver for electrical oscillations, the combination of an imperfect electrical contact, a local circuit through it, an induction-coil, the primary and secondary of which are both of wire not exceeding one-fiftieth of a centimeter in diameter, a capacity, a conductor connected to one end of the primary of the coil, a connection between the other end and the capacity and connections between the ends of the imperfect contact, the ends of the secondary of the coil and a condenser in one of the latter connections.

UNITED STATES PATENT OFFICE.

NIKOLA TESLA, OF NEW YORK, N. Y.

APPARATUS FOR TRANSMISSION OF ELECTRICAL ENERGY.

SPECIFICATION forming part of Letters Patent No. 649,621, dated May 15, 1900.

Original application filed September 2, 1897, Serial No. 650,343. Divided and this application filed February 19, 1900. Serial No. 5,780. (No model.)

To all whom it may concern:

Be it known that I, NIKOLA TESLA, a citizen of the United States, residing at the borough of Manhattan, in the city of New York, county and State of New York, have invented certain new and useful Improvements in Apparatus for the Transmission of Electrical Energy, of which the following is a specification, reference being had to the drawing accompanying and forming a part of the same.

This application is a division of an application filed by me on September 2, 1897, Serial No. 650,343, entitled "Systems of transmissions of electrical energy," and is based upon new and useful features and combinations of apparatus shown and described in said application for carrying out the method therein disclosed and claimed.

The invention which forms the subject of my present application comprises a transmitting coil or conductor in which electrical currents or oscillations are produced and which is arranged to cause such currents or oscillations to be propagated by conduction through the natural medium from one point to another remote therefrom and a receiving coil or conductor at such distant point adapted to be excited by the oscillations or currents propagated from the transmitter.

This apparatus is shown in the accompanying drawing, which is a diagrammatic illustration of the same.

A is a coil, generally of many turns and of a very large diameter, wound in spiral form either about a magnetic core or not, as may be desired. C is a second coil formed by a conductor of much larger size and smaller length wound around and in proximity to the coil A.

The apparatus at one point is used as a transmitter, the coil A in this case constituting a high-tension secondary, and the coil C the primary, of much lower tension, of a transformer. In the circuit of the primary C is included a suitable source of current G. One terminal of the secondary A is at the center of the spiral coil, and from this terminal the current is led by a conductor B to a terminal D, preferably of large surface, formed or maintained by such means as a balloon at an elevation suitable for the purposes of transmission. The other terminal of the secondary A is connected to earth, and, if desired, to the primary also, in order that the latter may be at substantially the same potential as the adjacent portions of the secondary, thus insuring safety. At the receiving-station a transformer of similar construction is employed; but in this case the longer coil A' constitutes the primary, and the shorter coil C' the secondary, of the transformer. In the circuit of the latter are connected lamps L, motors M, or other devices for utilizing the current. The elevated terminal D' connects with the center of the coil A', and the other terminal of said coil is connected to earth and preferably, also, to the coil C' for the reasons above stated.

The length of the thin wire coil in each transformer should be approximately one-quarter of the wave length of the electric disturbance in the circuit, this estimate being based on the velocity of propagation of the disturbance through the coil itself and the circuit with which it is designed to be used. By way of illustration, if the rate at which the current traverses the circuit including the coil be one hundred and eighty-five thousand miles per second then a frequency of nine hundred and twenty-five per second would maintain nine hundred and twenty-five stationary waves in a circuit one hundred and eighty-five thousand miles long and each wave would be two hundred miles in length.

For such a low frequency, which would be resorted to only when it is indispensable for the operation of motors of the ordinary kind under the conditions above assumed, I would use a secondary of fifty miles in length. By such an adjustment or proportioning of the length of wire in the secondary coil or coils the points of highest potential are made to coincide with the elevated terminals D D', and it should be understood that whatever length be given to the wires this requirement should be complied with in order to obtain the best results.

It will be readily understood that when the above-prescribed relations exist the best conditions for resonance between the transmit-

ting and receiving circuits are attained, and owing to the fact that the points of highest potential in the coils or conductors A A' are coincident with the elevated terminals the maximum flow of current will take place in the two coils, and this, further, necessarily implies that the capacity and inductance in each of the circuits have such values as to secure the most perfect condition of synchronism with the impressed oscillations.

When the source of current G is in operation and produces rapidly pulsating or oscillating currents in the circuit of coil C, corresponding induced currents of very much higher potential are generated in the secondary coil A, and since the potential in the same gradually increases with the number of turns toward the center and the difference of potential between the adjacent turns is comparatively small a very high potential impracticable with ordinary coils may be successively obtained.

As the main object for which the apparatus is designed is to produce a current of excessively-high potential, this object is facilitated by using a primary current of very considerable frequency; but the frequency of the currents is in a large measure arbitrary, for if the potential be sufficiently high and the terminals of the coils be maintained at the proper elevation where the atmosphere is rarefied the stratum of air will serve as a conducting medium for the current produced and the latter will be transmitted through the air, with, it may be, even less resistance than through an ordinary conductor.

As to the elevation of the terminals D D', it is obvious that this is a matter which will be determined by a number of things, as by the amount and quality of the work to be performed, by the condition of the atmosphere, and also by the character of the surrounding country. Thus if there be high mountains in the vicinity the terminals should be at a greater height, and generally they should always be at an altitude much greater than that of the highest objects near them. Since by the means described practically any potential that is desired may be produced, the currents through the air strata may be very small, thus reducing the loss in the air.

The apparatus at the receiving-station responds to the currents propagated from the transmitter in a manner which will be well understood from the foregoing description. The primary circuit of the receiver—that is, the thin wire coil A'—is excited by the currents propagated by conduction through the intervening natural medium from the transmitter, and these currents induce in the secondary coil C' other currents which are utilized for operating the devices included in the circuit thereof.

Obviously the receiving-coils, transformers, or other apparatus may be movable—as, for instance, when they are carried by a vessel floating in the air or by a ship at sea. In the former case the connection of one terminal of the receiving apparatus to the ground might not be permanent, but might be intermittently or inductively established without departing from the spirit of my invention.

It is to be noted that the phenomenon here involved in the transmission of electrical energy is one of true conduction and is not to be confounded with the phenomena of electrical radiation which have heretofore been observed and which from the very nature and mode of propagation would render practically impossible the transmission of any appreciable amount of energy to such distances as are of practical importance.

What I now claim as my invention is—

1. The combination with a transmitting coil or conductor connected to ground and to an elevated terminal respectively, and means for producing therein electrical currents or oscillations, of a receiving coil or conductor similarly connected to ground and to an elevated terminal, at a distance from the transmitting-coil and adapted to be excited by currents caused to be propagated from the same by conduction through the intervening natural medium, a secondary conductor in inductive relation to the receiving-conductor and devices for utilizing the current in the circuit of said secondary conductor, as set forth.

2. The combination with a transmitting coil or conductor having its ends connected to ground and to an elevated terminal respectively, a primary coil in inductive relation thereto and a source of electrical oscillations in said primary circuit, of a receiving conductor or coil having its ends connected to ground and to an elevated terminal respectively and adapted to be excited by currents caused to be propagated from the transmitter through the natural medium and a secondary circuit in inductive relation to the receiving-circuit and receiving devices connected therewith, as set forth.

3. The combination with a transmitting instrument comprising a transformer having its secondary connected to ground and to an elevated terminal respectively, and means for impressing electrical oscillations upon its primary, of a receiving instrument comprising a transformer having its primary similarly connected to ground and to an elevated terminal, and a translating device connected with its secondary, the capacity and inductance of the two transformers having such values as to secure synchronism with the impressed oscillations, as set forth.

4. The combination with a transmitting instrument comprising an electrical transformer having its secondary connected to ground and to an elevated terminal respectively, and means for impressing electrical oscillations upon its primary, of a receiving instrument comprising a transformer having its primary similarly connected to ground and to an elevated terminal, and a translat-

ing device connected with its secondary, the capacity and inductance of the secondary of the transmitting and primary of the receiving instruments having such values as to secure synchronism with the impressed oscillations, as set forth.

5. The combination with a transmitting coil or conductor connected to ground and an elevated terminal respectively, and means for producing electrical currents or oscillations in the same, of a receiving coil or conductor similarly connected to ground and to an elevated terminal and synchronized with the transmitting coil or conductor, as set forth.

6. The combination with a transmitting instrument comprising an electrical transformer, having its secondary connected to ground and to an elevated terminal respectively, of a receiving instrument comprising a transformer, having its primary similarly connected to ground and to an elevated terminal, the receiving-coil being synchronized with that of the transmitter, as set forth.

7. The combination with a transmitting coil or conductor connected to ground and to an elevated terminal respectively, and means for producing electrical currents or oscillations in the same, of a receiving coil or conductor similarly connected to ground and to an elevated terminal, the said coil or coils having a length equal to one-quarter of the wave length of the disturbance propagated, as set forth.

8. The combination with a transmitting coil or conductor connected to ground and to an elevated terminal respectively, and adapted to cause the propagation of currents or oscillations by conduction through the natural medium, of a receiving-circuit similarly connected to ground and to an elevated terminal, and of a capacity and inductance such that its period of vibration is the same as that of the transmitter, as set forth.

9. The transmitting or receiving circuit herein described, connected to ground and an elevated terminal respectively, and arranged in such manner that the elevated terminal is charged to the maximum potential developed in the circuit, as set forth.

10. The combination with a transmitting coil or conductor connected to ground and to an elevated terminal respectively of a receiving-circuit having a period of vibration corresponding to that of the transmitting-circuit and similarly connected to ground and to an elevated terminal and so arranged that the elevated terminal is charged to the highest potential developed in the circuit, as set forth.

UNITED STATES PATENT OFFICE.

FERDINAND BRAUN, OF STRASSBURG, GERMANY.

SPACE TELEGRAPHY.

No. 797,169. Specification of Letters Patent Patented Aug. 15, 1905

Application filed February 6, 1899. Serial No. 704,805.

To all whom it may concern.

Be it known that I, FERDINAND BRAUN, a subject of the German Emperor, and a resident of Strassburg, Alsace, German Empire, have invented a new and useful Improvement in Space Telegraphy, of which the following is a specification.

My invention relates to the transmission of electric signals without connecting-wires and comprises the improvements hereinafter described.

Electrical vibrations, although similar in their physical nature, may be classified for practical purposes into three groups. The first group includes vibrations which are created by the relative mechanical movements of magnets, coils, wires and so on. These are exemplified in the well-known ordinary alternating currents, as used for electric light and transmission of power. Their frequency will obviously be limited by the physical conditions of machinery.

A second group of electrical vibrations consists of oscillations which are produced by the discharge of Leyden jars, or condensers, with or without inductance-coils in circuit. The frequency of these oscillations, which is considerably higher than the frequency of the former group, can be calculated by well-known relations between capacity and inductance.

A third group of vibrations or oscillations is that first studied experimentally by the late Dr. Hertz, and in the production of these the capacity and inductance are not obtained by means of specially-provided Leyden jars, or condensers, and inductance-coils, but the capacity and inductance of ordinary conductors are used.

Hitherto the attention of inventors, occupied with the transmission of signals without the use of connecting-wires, by means of Hertzian or electromagnetic ether waves, has been principally confined to the use of such waves produced by the oscillations of the last-mentioned group, and one object has been to increase the frequency of these waves as much as possible. This is exemplified by the use of the Righi transmitter. For the transmission of such short waves it is essential, however, that the transmitting and receiving stations should be, so to speak, visible to each other; as stated by Hertz in one of his earlier papers concerning the transmission of electromagnetic ether waves and by subsequent experiments, it has been shown, that various material objects, such as sails, smoke, trees, buildings and the like, interposed between the two stations, weaken or in some cases entirely prevent communication between them. My invention is intended to obviate this inconvenience and I do this by making use of electrical oscillations belonging to the second group above mentioned which have only a small frequency compared with the frequency of the oscillations of the third group. By this means, owing to the greater length of the waves produced, these latter are able to pass through conductors if these are but of moderate thickness. Furthermore, obstacles in the path of waves will not project such sharply-defined shadows, the waves passing around them in a manner similar to that which sound-waves pass round obstacles. Another advantage in using slower vibrations or oscillations is that their potential and amplitude, and thereby the energy transmitted, are more easily increased. When the higher-frequency waves are used, produced by the oscillations of the third group above mentioned, there is a certain length of spark which must not be exceeded if the circuit is required to excite vibrations or oscillations; otherwise the vibrations or oscillations would be damped too much; but this means that the effective potential is limited, which, if oscillations of the second group are used either does not occur, or can be very easily avoided.

I have found by experiments that the oscillations produced by the discharge of Leyden jars of usual size in a circuit having moderate inductance, are very convenient for the purpose of transmitting signals.

In carrying out my invention, I make use of the well-known upwardly-projecting transmitting-wire, and receiving-wire connected to the coherer in the receiving-station. It is well understood in the art that the function of the former wire, which projects upwardly and to a considerable height, is to spread out or radiate the electromagnetic ether waves through the air, and of the latter wire to collect these waves and to conduct them to the coherer.

As the object of my invention is to use the waves created by the oscillations produced by the discharge of Leyden jars or other condensers, it is essential for my invention that the transmitting-wire be so related to the oscillation-circuit containing the Leyden jars that oscillations will be created in the transmitting-wire by the oscillations in said circuit. For this purpose the transmitting-wire

3701

is in accordance with the present invention connected conductively to the oscillation-circuit, as illustrated diagrammatically in the drawings.

A form of appanatus in which the transmitting-wire is not conductively connected to the oscillation-circuit but is inductively connected thereto is described and claimed in my application Serial No. 157,728, filed May 18, 1903, as a division of this application.

An oscillation-circuit comprising a Leyden jar or condenser and spark-gap, with or without an inductance-coil, is, and for a long time has been, well known to be a persistently-oscillating circuit, or a circuit in which its electrical equilibrium having once been disturbed, vibrations or oscillations continue for a considerable length of time. In other words, this circuit is a source of maintained or sustained electrical oscillations. This circuit I have likened to a "reservoir of energy," a portion of which is radiated from the transmitting-wire for every oscillation until there is no more energy left and the circuit ceases to vibrate.

In order that my invention may be clearly understood, I have shown in the accompanying drawings by way of example, some arrangements of circuits for transmitting signals by means of the electric oscillations above described.

Figure 1 illustrates diagrammatically a transmitting apparatus constructed in accordance with the invention. Fig. 2 shows a modified arrangement of the same.

In Fig. 1 a Leyden jar indicated at F has its inner and outer coatings connected through the spark-gap *a*, a coil P of small self induction or inductance being included in the oscillation-circuit which increases the normal inductance of such circuit. The inner coating is connected to the transmitting-wire M. It is well understood that the transmitting-wire may be of any suitable size. The jar is charged in the usual manner by means of an influence-machine, inductorium or other suitable means.

In place of one jar, two or more can be used connected in parallel or series. Fig. 2 for example shows two jars arranged in series, or as commonly called in "cascade."

The invention is not limited to the precise arrangements of circuits shown in the drawings, as these can be varied very considerably, and electric oscillations of low frequency suitable for transmitting signals according to my invention can be produced in various other ways.

Leyden jars have been used heretofore in connection with wireless telegraphy, but never before have the oscillation-circuits been conductively connected to the transmitting-wires so that the oscillations in said circuits create oscillations in the transmitting-wires which latter create and cause to radiate therefrom electromagnetic ether waves.

What I claim is—

1. In a transmitter for wireless telegraphy, the combination with an oscillation-circuit containing a condenser, of a transmitting-wire connected conductively with said circuit, substantially as and for the purpose stated.

2. In a transmitter for wireless telegraphy, the combination with an oscillation-circuit containing a condenser and a spark-gap, of a transmitting-wire connected conductively with said circuit, substantially as and for the purpose stated.

3. In a transmitter for wireless telegraphy, the combination with an oscillation-circuit containing a condenser and an inductance means for increasing the normal inductance of said circuit, of a transmitting-wire connected conductively with said circuit, substantially as and for the purpose stated.

4. In a transmitter for wireless telegraphy, the combination with an oscillation-circuit containing a condenser and a spark-gap and an inductance means for increasing the normal inductance of said circuit, of a transmitting-wire connected conductively with said circuit, substantially as and for the purpose stated.

5. In a transmitter for wireless telegraphy, a transmitting-wire provided with a spark-gap, a condenser connected across the spark-gap, and a source of electrical energy connected to the terminals of the spark-gap.

6. In a transmitter for wireless telegraphy, a transmitting-wire provided with a spark-gap, a condenser connected across the spark-gap, and a source of periodically-varying electromotive force connected to the terminals of the spark-gap.

7. In a transmitter for wireless telegraphy, a transmitting-wire provided with a spark-gap, a plurality of condensers connected across the spark-gap, and a source of periodically-varying electromotive force connected to the terminals of the spark-gap.

8. In a transmitter for wireless telegraphy, a transmitting-wire connected conductively with a closed oscillation-circuit.

9. In a transmitter for wireless telegraphy, a transmitting-wire connected conductively with a persistently-oscillating circuit.

10. In a system of wireless telegraphy, a transmitting-wire connected conductively with a source of persistent electrical oscillations.

11. In a system of wireless telegraphy, means for radiating electromagnetic waves of low frequency, comprising a transmitting-wire conductively connected with a source of persistent low-frequency electric oscillations.

In testimony whereof I have hereunto set my hand in presence of two subscribing witnesses.

UNITED STATES PATENT OFFICE.

FERDINAND BRAUN, OF STRASSBURG, GERMANY.

SPACE TELEGRAPHY.

No. 797,544. Specification of Letters Patent. Patented Aug. 15, 1905.

Original application filed February 6, 1899. Serial No. 704,605. Divided and this application filed May 18, 1903. Serial No. 157,728.

To all whom it may concern:

Be it known that I, FERDINAND BRAUN, a subject of the German Emperor, and a resident of Strassburg, Alsace, German Empire, have invented a new and useful Improvement in Space Telegraphy, of which the following is a specification.

My invention relates to the transmission of electric signals without connecting-wires and comprises the improvements hereinafter described.

The invention is a part of that for which an application, Serial No. 704,605, was filed by me February 6, 1899. In said application the advantage is shown which is arrived at by using Hertzian or electromagnetic ether-waves of lower frequency than the Hertzian and Righi waves mainly used before, and said application shows and describes the use of oscillations produced by the discharge of a Leyden jar or condenser with or without an inductance-coil in the oscillation-circuit, and a transmitting-wire conductively connected to the oscillation-circuit so that oscillations in said circuit create oscillations in the transmitting-wire, which latter create and cause to radiate therefrom electromagnetic ether-waves. This divisional application relates to apparatus in which the transmitting-wire is inductively connected with the oscillation-circuit.

An oscillation-circuit comprising a Leyden jar or condenser and spark-gap, with or without an inductance-coil, is, and for a long time has been, well known to be a persistently-oscillating circuit, or a circuit in which, its electrical equilibrium having once been disturbed, vibrations or oscillations continue for a considerable length of time. In other words, this circuit is a source of maintained or sustained electrical oscillations. This circuit I have likened to a "reservoir of energy," a portion of which is radiated from the transmitting-wire for every oscillation until there is no more energy left and the circuit ceases to vibrate.

The invention is illustrated by the accompanying drawings by way of example.

Figure 1 shows diagrammatically a transmitting apparatus according to the present invention. Fig. 2 illustrates a modification thereof.

In Fig. 1, F is a Leyden jar preferably of the usual size. An oscillation-circuit is provided containing said Leyden jar F, an air-gap *a* and the primary P of a suitable transformer, which primary coil will also act as an inductance-coil. One end of the secondary S of this transformer is connected to any point of the oscillation-circuit, as for example between the air-gap and the outer coating of the Leyden jar, and the other end to the upwardly-extending transmitting-wire M. By dimensioning properly the Leyden jars, the transformers, the coils &c. the most favorable results will be obtained.

In Fig. 2 an oscillation-circuit is provided containing two Leyden jars connected in series for reducing the capacity, and a primary coil P of a transformer, which also acts as an inductance-coil. One end of the secondary coil of the transformer S is connected with the transmitting-wire M, and the other end is shown prolonged and ending in an arrow to indicate that it may be prolonged by adding a suitable length of insulated wire or connected to some other suitable capacity area.

The use of the electric connection by means of a transformer between the oscillation-circuit and the transmitting-wire enables the potential to be obtained which is most fit for the production of electromagnetic waves. Experience has shown that transformed oscillations are very useful. Experience has shown also that the action of oscillating energy can be essentially increased by the invention, so that it is possible to overcome longer distances than it has been before.

The invention is not limited to the precise arrangements of circuits shown in the drawings, as these can be varied considerably. Therefore I do not limit myself to the particular arrangements shown, but

What I claim is—

1. In a transmitter for wireless telegraphy, the combination with an oscillation-circuit containing a condenser and the primary of a transformer, of a transmitting-wire connected with the secondary of the transformer, the other end of said secondary being connected to one plate of said condenser.

2. In a transmitter for wireless telegraphy, the combination with an oscillation-circuit

3702b

1093

containing a condenser and the primary of a transformer, of a transmitting-wire connected with the secondary of the transformer, the other end of said secondary being connected to a capacity area other than earth and having no direct connection with earth.

In testimony whereof I have hereunto set my hand in presence of two subscribing witnesses.

FERDINAND BRAUN.

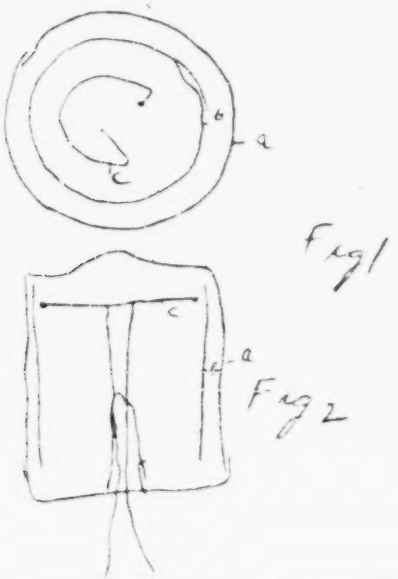
DEFENDANT'S EXHIBIT Q 6

Sketch made by Weagant at R. 1542



DEFENDANT'S EXHIBIT S-6

another instance of what was well known, the enormous use that medical skill and science was in promoting sympathetic relations between Europeans and Orientals. A medical man could set aside politics and religion, and establish himself in communication with the people of the country in a way which no one else could. It was a remarkable fact that they should be that evening in the centre of London, listening with interest to an account of a wild country in the centre of Asia. Could there be a stronger instance of the immense width of the English dominion and English interests? We had very strong interests in Afghanistan; it was not exactly within our frontiers; but its frontiers we had undertaken to protect, the line having been laid down by agreement between the two great European powers, which were both making for themselves empires in Asia—England and Russia. It was for that reason that those who sat at home, safe behind their sea-washed barriers, were responsible for the maintenance of the frontier, and the welfare of people at such a distance. There was no doubt the Amir was one of the most powerful and successful monarchs, perhaps, in Asia, and his was one of those curious kingdoms which had been left standing, notwithstanding the agglomerations of the great empires of Russia, China, Persia, and India. The people of Afghanistan were an agglomeration of tribes, but beyond that they were an assemblage of free men who, like ourselves, considered liberty one of the noblest gifts. They had always fought gallantly against the foreigner, and were determined, if possible, to have their country for themselves. We could all sympathise with people of that sort, and for that reason he cordially echoed the wish the Chairman had expressed that we should use every exertion to preserve the liberties of the Afghan people, and maintain its independence and integrity.

Colonel E. T. THACKERAY, R.E., C.B., V.C., said, one interesting feature of Afghanistan was the system of subterranean canals, or underground channels, which were made for connecting together the shafts sunk wherever water was expected to be found. Some of these canals were carried to a length of about 20 miles. These canals were supposed to have been originated by King Hushung, who was also supposed to have built the seven great cities of Afghanistan, besides Kabul. Earthquakes were extremely common in that country.

A vote of thanks to Mr. Gray for his interesting paper was carried unanimously, and briefly acknowledged.

FOREIGN & COLONIAL SECTION.

Tuesday, February 20, 1894; Sir ALBERT KAYE ROLLIT, LL.D., M.P., Vice-President of the Society, in the chair.

The paper read was "The Arts and Industries of Belgium, and the Antwerp Exhibition, 1894," by Edouard Séve.

The paper and discussion will be printed in the next number of the *Journal*.

TWELFTH ORDINARY MEETING.

Wednesday, Feb. 21, 1894; Sir RICHARD WEBSTER, Q.C., M.P., Chairman of the Council, in the chair.

The following candidates were proposed for election as members of the Society:—

Kent, Walter G., 199, High Holborn, W.C.
Niven, David Coats, Oriental Gas Company, Calcutta.
Walker, Ernest Octavius, C.I.E., Brook-hill-house, Teignmouth, Devon.
Walton, Joseph, Zetland-buildings, Middlesbrough.
Williamson, S. H., Mayor of Worcester

The following candidate was balloted for and duly elected a member of the Society:—

Bruff, Charles Clarke, Coalport, Shropshire.

The paper read was—

ELECTRIC SIGNALLING WITHOUT WIRES.

BY W. H. PREECE, C.B., F.R.S.

What is electricity? Few venture to reply boldly to this question, first, because they do not know; secondly, because they do not agree with their neighbours, even if they think they know; thirdly, because their neighbours do not agree among themselves, even as to what to apply the term. The physicist applies it to one thing, the engineer to another. The former regards his electricity as a form of ether, the latter as a form of energy. I cannot grasp the concept of the physicist, but electricity as a form of energy is to me a concrete fact. The electricity of the engineer is something that is generated and supplied, transformed and utilised, economised and wasted, meted out and paid for. It produces motion of matter, heat, light, chemical decomposition, and sound; while these effects are reversible, sound, chemical decomposition, light, heat, and motion reproduce those effects which are called electricity.

Faraday's immortal researches, Clerk-Maxwell's prophetic investigations, and Hertz's convincing experiments, have definitely and conclusively proved the existence of one medium throughout all space, called the

JUN 6 1933

ether, through which waves of energy, called radiations, are propagated with the same velocity, but in different forms and with different frequencies, although all of the same character. At one end of the scale we have actinic disturbances producing photographic impressions; at the other end of the scale electric waves producing electromagnetic disturbances while the intermediate radiations give light and heat. Actinic waves are extremely minute and number many millions per second, electric waves are very long and may number only hundreds per second. Like light waves, they are propagated in straight lines, they obey the laws of reflection, they are refracted, they are subject to interference, and they may be even polarised.

We have to consider electric waves to-night, and I want to show you how we are gradually, by patient plodding, creeping along towards the period when I hope we shall be able to make real practical use of such electromagnetic disturbances.

If we take a conductor through which a rapidly alternating current is being supported by any means, it throws the ether which surrounds it into oscillations. Energy is thus radiated away in electric waves. These electric waves spread out in all directions, as do waves of light, and if they fall on similar conductors properly placed and sympathetically prepared, these waves of energy are transformed back again into alternating currents which give evidence of their presence. Their presence is indicated by a telephone if the frequency of the alternating currents is brought within the range of the ear. Hertz and his followers experimented with waves of much shorter length, and with sparks in air, but all my experiments have been made with telephones and with waves comparable in frequency with those of sound.

The prime source of energy has been either a steam-engine or a galvanic battery. This has produced, by suitable machinery, rapidly intermittent or alternating currents, which have been transmitted through a primary circuit. At some distance away from this circuit there has been a secondary telephone circuit, and between these two circuits the only connecting medium has been the ether, which has been thrown into electric oscillation, and it has been across this space that I have been signalling without wires. In all cases, the primary currents were of such a frequency as to produce a musical note in the telephones fixed in the secondary circuit, which could easily be read, if sent in the dots and dashes of the Morse code.

Signalling through space is very fascinating. I have now for ten years been steadily investigating the subject. In 1884, messages sent through insulated wires, buried in iron pipes in the streets of London, were read upon telephone circuits erected on poles 80 feet away on the housetops. It was imagined this must have been due to accidental connections, or to earths, or to any other cause but the true one, namely, electromagnetic induction, or the influence which one conductor conveying currents exercises on another parallel to it, when separated by a dielectric, or by mere space, that is, by the ether.

It is very difficult to convert the human mind from one mode of thought to another. We have been so trained to regard currents of electricity as something flowing in one complete unbroken circuit, that their temporary condition as waves of energy in space is difficult to realise. One irresistibly endeavours to trace them to earth conduction, to leakage, to contact, or to some more well-known cause. Ten years of unremitting experiment have, however, proved the effects I am bringing before you to be due, primarily, to radiation, and not to conduction.

In 1885, a very exhaustive series of experiments was made for me by Mr. A. W. Heaviside, in the neighbourhood of Newcastle, to find out how far the distance between the wires affected the results. Ordinary telegraph working currents produced disturbances at a distance of 2,000 feet, while effects on parallel lines of telegraph, 10½ miles apart, between Durham and Darlington, were perceptible. Distinct speech was carried on through a distance of one quarter of a mile. We even obtained indications of current between the east and west coasts, 40 miles apart, but these observations were vitiated by conduction through the large network of telegraph wires between those two places. I brought the subject before the British Association at their meeting in Birmingham in 1886. The district between Gloucester and Bristol, along the banks of the River Severn, was then selected, where for a length of 14 miles, and at an average distance apart of 4·5 miles, no intermediate disturbing conductors existed. I was able to experiment with complete metallic circuits, the return wires passing far inland, in the one case through Monmouth, and, in the other, through Stroud. Weak disturbances were detected. These experiments

11032

were repeated, with more experience and greater success, in 1889. Similar experiments were conducted along the valley of the Mersey. A new trunk line of copper wires that was being erected between London and the coast of North Wales was then experimented upon, and some interesting results were obtained in the district between Shrewsbury and Much Wenlock, and between Worcester and Bewdley.

An admirable series of experiments were made for me in the same year, by Mr. Gavey near Porthcawl, in South Wales. There we have a wide expanse of sand well covered by the tide and giving the opportunity to observe the effects in water as well as in air. Squares of insulated wire, 1,200 yards long, were laid side by side at various distances apart, and smaller squares were suspended above each other on scaffold poles. The effects were observable equally in air and water. The results were absolutely conclusive that we were working with the so-called electro-magnetic induction, and all subsequent experience has confirmed this conclusion.

These further experiments were brought before the British Association at Manchester in 1887.

Thus the theory of the thing had been thoroughly threshed out, and it only waited for some convenient opportunity to give it a practical test.

When the Royal Commission to inquire into electric communication between the shore and lighthouses and light vessels was appointed in June, 1892, the question was started. Here was the opportunity. My proposal to test this means of communication in a practical way was submitted by the Postmaster-General to the Treasury. The expenditure was sanctioned, and the experiment made. The results were submitted by me to the Electric Congress which was held in Chicago in August in 1893.

The Bristol Channel proved a very convenient locality to test the practicability of communicating across a distance of three and five miles. Two islands, the Flat Holm and the Steep Holm, lie off Penarth and Lavernock Point, near Cardiff, the former having a lighthouse upon it. On the shore two copper wires weighing 400 lbs. per mile, forming one conductor, were suspended on poles for a distance of 1,267 yards, the circuit being completed by the earth. Experience justified the assumption that the earth acts as a conductor, and that it practically replaces the fourth side of the rectangle used in the previous experiments. We have not yet determined the actual position of the resultant line of this earth side, but further experiments are being made. On the sands at low water mark, 600 yard from this primary circuit and parallel to it, two ordinary gutta-percha covered copper wires and one bare copper wire were laid down, their ends being buried deep in the ground by means of bars driven in the sand.

One of the gutta-percha wires was lashed to an iron wire to represent a cable. These wires were periodically covered by the tide which rises here at springs to 33 feet. On the Flat Holm, 3·1 miles away, another gutta-percha covered copper wire was laid for a length of 600 yards.

There was also a small steam launch having on board several lengths of gutta-percha covered wire. One end of such a cable, half a mile long, was attached to a small buoy, which acted as a kind of float to the end, keeping the wire suspended upon or near the surface of the water while the launch slowly steamed ahead against the tide. It was paid out and picked up in several positions between the primary circuit and the islands.

The apparatus used on shore was a 2 horse-power portable Marshall's steam-engine, working a Pike and Harris's alternator, sending 192 complete alternations per second at a voltage of 150, and of any desirable strength up to a maximum of 15 ampères. These alternating currents were broken up into Morse signals by a suitable key and sent along the primary circuit. The signals received on the secondary circuit produced sound and were read on a pair of telephones—the same instruments being used for all the experiments.

The object of the experiments was not only to test the practicability of signalling between the shore and the lighthouse, but to differentiate the effects due to earth conduction from those due to electromagnetic induction, and to determine the effects in water.

It was possible to trace, without any difficulty, the region where the signals ceased to be perceptible from currents, due to earth conduction, and where they commenced to be solely due to electric waves. This was found by allowing the paid-out cable, suspended near the surface of the water, to sink. Near the shore, no difference was perceptible, whether the cable was near the surface or lying on the bottom, but a point was reached where all sounds ceased as the cable sank, but were recovered again when the cable came to the surface.

The total absence of sound in the submerged cable rather surprised me, and it leads to the conclusion, either that the waves of energy are dissipated in the sea water, or else that they are reflected away from the surface of the water like rays of light. I believe implicitly in the latter explanation. Subsequently, experiments on the sands in the Conway Estuary showing the relative transparency of air and water to these electric waves, tend to support the latter deduction, for if waste of energy took place in the water, the difference would be more marked than was actually found to be the case. It was 6 per cent. only. As it is, we have ample evidence that the electric waves are transmitted to considerable distances through water, though how far remains to be found out.

There was no difficulty in communicating between the shore and Flat Holm. Messages were read. Mr. Gavey, who was making the experiment on the island, wrote me, "There was then a somewhat lengthened pause, due to a slight derangement of the machinery on the mainland, but at 2 p.m. I heard clearly and distinctly the following, 'Here Haskayne' (one of his assistants) 'with a message from Mr. Preece for Mr. Gavey.'" I was in London that day. "Then followed the announcement of the sad and sudden death of Mr. Graves, which cast a gloom over the success of the experiment. It seemed an extraordinary fact, that the first readable message transmitted for such a distance by such means should announce the death of the head of the Technical Department."

The distance between the two places was 3½ miles. The attempt to speak between Lavernock and Steep Holm was not so successful. The distance was 5¾ miles, but though signals were perceptible, conversation was impossible. There was distinct evidence of sound, but it was impossible to differentiate the sounds into Morse signals. We were just on the limit of audibility, and we were using our available maximum power. If either line had been longer, or the primary currents stronger, we should have spoken as was done at Flat Holm.

As the laws governing these effects were by no means so clear and conclusive as such probing and enquiring deserved, Mr. Gavey and Mr. Kempe conducted for me a very careful series of experiments near Frodsham, on the estuary of the Dee, which was found to be a more convenient locality than Conway, and the very satisfactory results obtained will shortly be published. The [illegible] so clear that, given the [illegible] which it is desired to communicate, [illegible] mere matter of calculation to show what [illegible] to be done. It would be quite easy to [illegible] between France and England, or [illegible] Straits of Dover.

There happens to be a very convenient [illegible] accessible loch in the highlands—Loch Ness [illegible] —forming part of the route of the Caledonian Canal between Inverness and Hanoaver—having a line of telegraph on each side of it. Five points on each side of this loch were taken and so arranged that any fractional length of telegraph wire on either side could be taken for trial. Ordinary, and not special apparatus was employed, sending messages, as before, by Morse signals, and speaking by telephone across a space of one and a quarter miles was found practical, and in fact, easy. Indeed, the sounds were so loud, that they were found sufficient to form a call for attention.

The following apparatus was in use on each side of the loch for the transmission of Morse signals.—A set of batteries consisting of [illegible] dry cells, giving a maximum voltage of [illegible] rapidly revolving rheotome which broke [illegible] current into a musical note; a Morse key by which these musical notes could be transformed into Morse signals; resistance coils and ampères meters to vary the primary current; two bell telephones joined in multiple arc to act as receivers. For the transmission of actual speech simple granular carbon microphones, known as the Dieckert's, were used as transmitters, and a current of 2 ampères was maintained through these and two Bell telephones in circuit with the line wire.

Any lingering fear that earth conduction had principally to do with these results was removed by making the earth's terminals on the primary circuit at one end at Inverness nine miles away, and at the other end in two directions in a parallel glen about six miles away. The early experiments of 1897, in the valley of the Severn, had placed this question of earth interference beyond the region of doubt, but earth conduction, as a main factor in the results, is still believed in by critics. The function performed by the earth has been thoroughly developed in the Frodsham experiments, and will be discussed subsequently.

One very interesting fact observed at Loch Ness was that there was one particular frequency in the primary circuit that gave a decided maximum effect upon the telephones in the secondary circuit. This proves the pre-

3101

sence of resonance, and is, of itself, a fact sufficient alone to prove the effects as being due to the transformation of electric waves into electric currents.

It is well known that every telephone has one particular note—the natural note of the disc—to which it responds better than to any other, but this resonant effect far exceeded in magnitude any difference due to the natural pitch of the disc. It was not the natural note.

Conversation by telephone, though possible, was not however practical. Still, it is something to have transmitted speech by electricity across an air space of 1½ miles. We had this curious condition, that at some intermediate point the energy of the human voice was found side by side in two different forms—sonorous vibrations in the air, and electric waves in the ether.

There is now no difficulty in communicating with outlying islands if the conditions are favourable. The Northern Commissioners of Lights are anxious to establish electrical communication with the Muckle Flugga Lighthouse, at the extreme north of the Shetland Islands, but the place is so inaccessible that, though the conditions are favourable and signalling without wires is possible and simple, it would be more prudent to adopt the more expensive plan of a submerged cable. I would rather inaugurate the system nearer home, where it could be watched, nursed, and improved. Anyhow, it is something to be able to report that we have now acquired a practical system of signalling across space without the necessity of using wires.

Although this short paper is confined to a description of a simple practical system of communicating across terrestial space, one cannot help speculating as to what may occur through planetary space. Strange, mysterious sounds are heard on all long telephone lines when the earth is used as a return, especially in the calm stillness of night. Earth currents are found in telegraph circuits, and the Aurora Borealis lights up our northern sky when the sun's photosphere is disturbed by spots. The sun's surface must, at such times, be violently disturbed by electrical storms, and if oscillations are set up and radiated through space, in sympathy with those required to affect telephones, it is not a wild dream to say that we may hear on this earth a thunderstorm in the sun.

If any of the planets be populated with beings like ourselves, having the gift of language and the knowledge to adapt the great forces of Nature to their wants, then if they could oscillate immense stores of electrical energy to and fro in telegraphic order, it would be possible for us to hold commune by telephone with the people of Mars.

DISCUSSION.

Mr. PREECE, in answer to a question, stated that the experiments described were performed during the severe weather of last week, and that the wind had no effect upon the results.

Mr. W. GRANVILLE said he was not yet converted to the belief that the effects described were produced by induction, or radiation through space, and not by conduction or leakage; but there was one test which would decide the question. An induced current was only capable of producing a temporary action, whereas a current set up by conduction remained permanent as long as the primary current acted. When, in 1842, Professor Morse bridged a river in America by a somewhat crude method, resembling that shown on the diagram, the apparatus then used was only capable of responding to currents of a certain duration, certainly not to those of such small duration as would be produced by induction. Somewhat later Mr. Preece succeeded in bridging the Solent by a similar method, and he took it the instruments then in vogue were such as would only respond practically to currents of somewhat long duration; and there, again, there was simply the effect of conduction. Some years ago, in conjunction with the late Mr. Willoughby Smith, he had the satisfaction of carrying out a series of experiments at Yarmouth, where they succeeded in communicating from the shore to a small boat about a quarter of a mile off by means of two earth plates carried out to sea, but remaining at a distance of a quarter mile from the boat. Those signals were clearly produced by conduction, for they placed a galvanometer in the circuit, and found that, just as long as the battery current remained on, was it deflected, so that the result could not possibly be produced by induction. There had also been experiments by the Telegraph Construction and Maintenance Company, with a view to communicating with lighthouses; and at Alum Bay they communicated with the Needles through a non-continuous cable, bridging a distance of some 60 yards. In that case, a vibrator and telephone was first tried, but afterwards they substituted for it an ordinary galvanometer; and there they ascertained that the effect was produced by a permanent current, and, therefore, by conduction. With regard to the distance one could signal by means of induction through air, it was found, as the result of a large number of experiments, that if they took two spirals similar to those on the table, the sound fell off very rapidly, as the distance increased, and that with a very strong battery current

3710

4105

it was impossible to bridge a greater distance than about 100 yards. The same result was noticeable in the experiment shown that evening. He therefore must remain unconverted until Mr. Preece was able to inform them of the fact that he had placed a galvanometer in the circuit.

Mr. ALEXANDER SIEMENS said Mr. Preece had the great advantage over most of those present that he had conducted experiments on this most interesting subject, while they had not. He understood him to say that in one of his experiments he used two metallic circuits, so that there could be no doubt as to their being real induction, and not conduction currents which he was dealing with. There was one point to which particular attention should be called, viz., that in one case he had succeeded in calling up the other party. In some of the experiments the difficulty was that you had, by means of a boat, or in some other way, to fix the time at which the experiment was going to be made, in order that the man at the other side might be on the watch, but, in communicating with a lighthouse, it was very important to be able to call to your correspondent when you wanted him. If it was necessary, first, to send an ordinary telegram to say you were going to send a message, you might as well send it all at once. No doubt this method of signalling would be much further developed in the able hands in which it was, and a good deal might be expected from it in future.

Major-General FESTING, F.R.S., said he did not quite gather whether the result of the experiments in the Bristol Channel was to show that the two wires would respond to each other if they were both in the water. He understood that they would, if they were both in the air, or both in the water, but that if one were in the air and the other in the water, they would not.

Lieut.-Col. CUNNINGHAM, R.E., said Mr. Preece seemed to lay great stress on the fact that this inductive effect took place through the ether, and that it would probably take place equally in a vacuum. All the experiments were made across water, but he did not catch whether the wires were on both sides up in the air, or on one side in the air, and on the other in the water. He would also ask if there was any advantage in the long wires being parallel to each other, and further, what was the function of the cable paid out by the steam-launch.

Mr. CHARLES BRIGHT said it was a question at a recent meeting of the Society whether submarine cables or land lines were preferable, and the majority of speakers seemed in favour of land lines. He did not agree in that, but these experiments of Mr. Preece's seemed to point to another method of getting out of the difficulty in cases where a submarine cable was not sufficiently durable, as for instance for communication between lightships and the shore, owing to the continual chafing of the cable on the bottom and against the moorings. In conclusion, he would ask those studying this subject in future to change the title, and he did so in the interest of shareholders and cable contractors, who might think their occupation was gone. It was not really telegraphing without wires, because it appeared that considerable lengths of wire were necessary.

Mr. PREECE, in reply, said he was sorry Mr. Granville should have suggested that he was such a poor electrician as not to have tried the experiment he suggested. One of the first experiments he ever took part in was in the year 1853, when he assisted Mr. Lindsay in endeavouring to communicate across rivers by means of conduction currents. They made a tank to represent a river, and produced very capital results. He had often experimented in that direction, and, as Mr. Granville said, they succeeded in communicating across the Solent, through a broken cable from Hurst Castle, by means of those currents. He did not suppose anybody—unless it were Mr. Granville himself, or Mr. W. Smith—had devoted more attention to conduction currents through water or earth than he had. But there was as much difference between communicating by current through the air and by means of radiation as there was between having a room illuminated by electricity and taking hold of a red-hot poker. All his experiments had been verified by some such system as that adopted on Loch Ness, or by the use of metallic circuits, as was done in London, and also on the Severn and Conway lines. It was quite impossible to conceive that when you had two coils in the air, which were kept wide apart, that there could be any earth action of any sort. Mr. Granville drew attention to the fact that with the two coils he had shown, the sound diminished very rapidly as they were separated. That was so with coils, but if, instead of coils, the wires had been stretched out in straight lines, the distance through which you could communicate increased with the length of the wire; so that if Mr. Granville could communicate with coils 100 yards apart, the probability was that if the same wire had been stretched out straight the distance would have increased to a mile or more. Mr. Siemens had called attention to an important point. The one great difficulty in the earlier experiments was that there was no means of calling attention, but at Loch Ness the sound was so loud at 1¼ mile distance that it amounted to a call. The loudness was simply dependent on the materials and means used. With regard to the effects in air and in water on the South Wales coast, and also in the Conway estuary, the sounds were all reproduced in water as well as in air. When the conditions were the same, the effect would be the same. At Lavernock Point, the wires were on 20 feet

3711

4106

poles on the top of a cliff about 70 feet above high-water mark; in this case the electric waves did not pass through the water, they struck the water at a very low angle, which was probably for those waves the angle of total reflection, and the absence of any effect when the cable was sunk, was to him a proof that the waves did not penetrate the water. Had the primary wires been under water there would have been an effect on the submerged cable. He had not experimented in a vacuum, but always either in air or water. How far the air or water took any part in the transmission he could not say, but he had no doubt that the effects would all be traced to the same agency as operated in the case of light and heat, viz., the oscillations of the ether. It was essential to the effect that the wires should be parallel. If the wire on the Flat Holm were perpendicular to the one on Lavernock point he did not think any effect would be produced. The whole theory had been worked out; it was rather complicated and difficult, but he hoped before long to be in a position to write another paper on it. The object of the cable from the launch was first of all to see how far the effects of the earth currents extended, and where the effect of radiation alone appeared. They found that close in shore it made no difference whether the wire was on the surface or submerged, but when they got to a certain distance the difference between the effect of flotation and submersion became evident, and at length submersion caused the effect to disappear entirely. They experimented in that way inland as well as at sea, and inland they were able to plot out the earth currents; they had been plotted, not only there, but for Liverpool, London, and several other places. The object of having the cable suspended was to endeavour to differentiate between the radiations which were evident on the surface, and the earth currents which must have been evident on the surface as well as at the bottom of water. He must admit that the title of the paper was somewhat misleading, but he hoped he had made amends in the concluding particulars in which he had referred to hearing a thunderstorm in the sun, and that he had established some claim to the 300,000 francs which were now lying somewhere in Paris, having been offered as a premium to the man who first showed how to communicate with the inhabitants of Mars.

The CHAIRMAN, in proposing a hearty vote of thanks to Mr. Preece, said the paper had been to him quite a revelation as to matters of which he had hardly ventured to dream as possible. He thought the objection to the title of the paper was rather hypercritical, because ordinary people always understood telegraphing by wire as meaning through the wires going from one station to the other, and these parallel wires not connected would rather be looked upon as the sending and receiving instruments. He hoped, therefore, that the same name would be adhered to in any further development of the subject. He was interested in Mr. Granville's observations, but he, at once, thought of the answer which Mr. Siemens gave as being probably the correct one, and that where there were two complete insulated metallic circuits, the effects could not be due to leakage. He could not help thinking, also, having regard to what was known about induced currents, that the fact that no appreciable current was apparent in the receiving wire when it was perpendicular to the sending wire, would seem to indicate that the effect was produced by radiation or induction. He hoped on some future occasion they would have the privilege of hearing from Mr. Preece of the further development of this subject; one branch of it at least deserved further investigation, and that was the suggestion that the electric waves were reflected from the surface of the water. It was obvious that that would account for the fact that there was no apparent transmission from air to water, or from water to air, while at the same time there was transmission when both wires were either in air or in water. Possibly, also, the theory that the medium of transmission was what was understood as ether, was capable of further investigation.

The vote of thanks was carried unanimously, and the meeting adjourned.

Correspondence.

MODERN DEVELOPMENT OF ILLUSTRATED JOURNALISM.

MR. JOHN LEIGHTON, F.S.A., writes:—Mr. Townsend seems to have ignored the early stages of process, where the artist became his own engraver, and laid his own lines before photography and chemistry engraved them for him. I well remember that it was early in the forties that one of the Fourdriniers—a son of the inventor of the paper-making machine—had a method that he called gypsograph, it was a drawing with a point made through a surface of plaster down to a plate, and into which lines a stereotype cast entered, producing a relief block, that when bold was effective. Then there was the *Procédé Comte* by which many handsome works were done in Paris, and one has only to instance *L'Art pour tous* and the very large natural history subjects by Karl Bodmer, of Barbeson, that were first published in "*L'Illustration*" to see how the artist's touch was maintained, as in an etching. Then, again, there was "*La Vie Moderne*," an imitation of "*The Graphic*," only it was all process. A system that I employed in my "Suggestions in Designs," consisting of 1,100 designs, done in Paris by the Frères Comte and published about 1878, and printed on a tint, in a belief that it would defy photographic reproduction,

UNITED STATES PATENT OFFICE.

LEE DE FOREST, OF NEW YORK, N. Y., ASSIGNOR TO DE FOREST RADIO TELEPHONE AND TELEGRAPH COMPANY, OF NEW YORK, N. Y., A CORPORATION OF DELAWARE.

RADIOSIGNALING SYSTEM.

Application filed September 23, 1915. Serial No. 52,176.

To all whom it may concern:

Be it known that I, LEE DE FOREST, a citizen of the United States, residing in the city of New York, county of Bronx and State of New York, have made a certain new and useful Invention in Radiosignaling Systems, of which the following is a specification.

This invention relates to radio signaling systems.

The object of the invention is to provide a radio signaling system which is simple and efficient in operation.

Further objects of the invention will appear more fully hereinafter.

The invention consists substantially in the construction, combination, location and relative circuit arrangements all as will be more fully hereinafter set forth, as shown in the accompanying drawing and finally pointed out in the appended claims.

Referring to the drawing, Figs. 1, 2, 3, all show various circuit arrangements embodying my invention.

In accordance with my present invention, I propose to employ an evacuated vessel with hot and cold electrodes therein, known as the audion, together with suitable circuit connections to cause the audion to operate as a generator of undamped oscillations, and to so arrange the circuit connections to cause the audion to operate as a generator of undamped oscillations, and to so arrange the circuit connections referred to so as to allow such a generator to also be employed as a detector. The underlying principle of my present invention as will be more fully described, is the association, preferably by inductive coupling means, of the circuits of the cold electrodes of the audion.

In Fig. 1 I have shown a simple circuit arrangement for accomplishing the objects of my invention wherein D is the exhausted vessel, F the hot or filament electrode, and A is the battery for heating the same in the usual and well known manner and controlled by the resistance R_1 as shown in Fig. 4, if desired. G designates the grid or "input" electrodes and W the wing or "output" electrodes. Preferably, and as shown, though I do not desire to be limited in this respect, the wing and grid electrodes are arranged in pairs, both grids and both wings being connected in parallel. The input electrodes G are connected to one side of the filament F by a circuit including therein one coil of a transformer L_1. The output electrodes W are likewise connected to the filament F by a circuit including the coil L_2 of the transformer, and the usual source of voltage such as battery B or other direct current source with its positive terminal connected to the cold electrodes W through the telephone or signal indicating device T, as shown.

In series with the grid or input electrodes G and in the circuit thereof I propose to place a stopping condenser C, and to shunt around this condenser a high and preferably non-inductive resistance R, of from 25,000 to 100,000 ohms.

The transformer whose coils are L_1 L_2 may be a "telephone transformer" as shown, with the coils having several thousands turns each surrounding an iron core I, in which case the system will oscillate at "audio" or low frequencies, or the windings may contain only a few hundreds of turns each, of several milli-henries inductance, and the coils more or less spatially separated or "loosely coupled" in which case the system will oscillate at high or "radio" frequencies.

In the first case, that is, when the system is oscillating in "audio" frequencies the system becomes a "siren" and will generate powerful telephonic currents having a clear musical note heard in the telephone receiver T. The pitch of this note can be varied by altering the inductance of either of the coils L_1 L_2 in any well known manner, or by altering their coupling as by withdrawing from the transformer the iron core I, or by varying the distributed capacity of the winding or the spatial relation of the windings, or the capacity of the condenser C, the value of the resistance R, or the potential of the battery B, or the brightness of the filament F in any manner well known in the art.

When such an oscillating system as shown in Fig. 1, is employed for generating radio frequencies, the capacity of the ordinary telephone wires leading to the telephone receiver or signaling device T is usually sufficient to form a by-path around the high impedance and high resistance of this device. The impedance of source B to the

3738

radio frequency oscillations, I have found to be insufficient to materially dampen the same. My invention as defined in the claims is not to be limited in this respect however, for other expedients will readily suggest themselves to those skilled in the art.

If the system described is to be employed as a generator of high frequency oscillations for transmission purposes the signal device T may be a trans-mitter if desired. An alternative arrangement is shown in Fig. 2 wherein a key indicated at K is inserted in the antenna earth system. As it is obvious that my invention applies to either transmitting or receiving systems, I wish it to be understood that by the term "signal device," as used throughout the specification, I mean broadly either a transmitter or a receiver of signals.

When an audion with its cold electrodes associated or inter-linked as shown, is used as a receiving system its ordinary sensitiveness as a detector is many times increased by virtue of the "kick back" or progressively amplifying effect of the received signal impulses.

In Fig. 2 I have illustrated a "compound audion" containing two insulated grid members G_1 and G_2, and two insulated wing members W_1 and W_2, each of the four electrodes being connected to the filament F by a circuit containing inductances L_1, L_3, L_2, and L_4, respectively. The coils L_1, L_2, may be inductively associated as shown, and likewise inductances L_3, L_4, may be inductively associated, so as to allow reaction of the one upon the other in each pair.

As shown, I prefer to associate the grid nearest one wing with the current of the wing lying furthest away, usually on the opposite side of the filament, as thereby I find that the reaction of the circuits upon each other is the most violent. Each wing W_1 W_2, has, preferably, its own source of electro motive force as indicated at B_1, B_2, respectively, although I am not to be limited in this respect as it is obvious that a common source may be employed. In the circuit of the sources B_1 and B_2, I employ telephone receivers T_1, T_2, preferably, one receiver for each ear of the operator. I employ the usual stopping condensers C_1 and C_2 in the circuits of the grids G_2 and G_1, respectively, and the variable capacities C_3 and C_4, shunted around the coils L_1, L_3, to render the grid circuits oscillatory. The coils L_1, L_2, and L_3, L_4 of the two oscillating circuits are associated inductively or otherwise to the same antenna-earth system comprising the usual elements N, L_5, C_5, L_6, and E, as shown, whether the arrangement be used for receiving or transmitting signals.

When using the arrangement shown in Fig. 2, as a generator of alternating currents the sources of the wing currents, B_1 and B_2, respectively, should be of high voltage, as for example, direct current generators of from 600 to 1200 volts.

In the antenna-earth system, I show a transmitting key K connected directly therein. I also employ a hand operated switch S shunted around the same to cut the key K out when the system is used as a receiving system. The periodicities of the oscillating circuits L_1, C_3 and L_3, C_4, should be made the same, or nearly the same by properly adjusting their respective capacities or inductances. If the natural rates of oscillation of these two circuits are not quite the same, beats or interferences are set up in the antenna, resulting in a harmonic variation of amplitudes of the radiated wave train which may be of practical value when signaling to receiving stations where the receiver can give audible responses only to interrupted or intermittent trains of waves.

It will be noted that in accordance with my invention, the connection of the terminals of the wing and grid coils is important. I have found that the oscillations set up are much more intense when one end of one of these coils is connected to the grid or plate as the case may be, than when the opposite end of that coil is thus connected. In other words, by reversing coil L_2 relative to coil L_1, the oscillations set up may be found to be much more intense than before such reversal of connections. The principle here involved is that the phase of the two pulsating currents in the coils L_1 and L_2, shall be so displaced relative to each other that a positive charge or surge upon the wing electrodes shall be next followed by a negative charge or surge upon the grid, the effect of this being that thereby an increase of current through the coil L_2 to the wing results in a succeeding increase in the resistance of the gas path between the wing and the filament electrodes, and conversely, a diminution in the current from the wing to the filament electrodes results in a succeeding decrease in the resistance of the path. It is by these means that one circuit is enabled to react upon the other so that successively increasing pulsations are set up in the two associated circuits until the losses by resistance, leakage and load, are equal to the increment of energy supplied from the battery or source B B_1, B_2 whereupon a stable condition of oscillation or pulsation is attained.

In Fig. 3 I have shown a modified arrangement wherein the wing and grid circuits are inductively associated as in Fig. 1, through coils L_1 and L_2 around which are shunted capacities C and C_3, respectively. In this arrangement I prefer to associate the grid circuit with the antenna earth circuit through inductance L_5 of the antenna

system. In this instance I shunt a capacity C_2 around the inductance P as shown. The core I is also used in coupling between the oscillating circuits of the cold electrodes, and the reaction effect is secured between these circuits as hereinbefore described.

It will be understood that many other circuit arrangements will readily occur to those skilled in the art without departing from the broad scope of my invention as defined in the claims. Therefore, having set forth the objects and nature of my invention, and having shown and described various embodiments thereof, what I claim as new and useful and of my own invention and desire to secure by Letters Patent, is,—

1. In a radio signaling system, an evacuated vessel including hot and cold electrodes therein, said cold electrodes being located at relatively different distances from said hot electrode, separate circuits connecting each of the cold electrodes to the hot electrode, said circuits being inductively associated.

2. In a radio signaling system, an evacuated vessel containing hot and cold electrodes therein, said cold electrodes being located at relatively different distances from said hot electrode, separate oscillating circuits connecting each of said cold electrodes to said hot electrode, said circuits being inductively associated.

3. In a radio signaling system, an evacuated vessel including hot and cold electrodes therein, said cold electrodes being located at relatively different distances from said hot electrode, separate circuits connecting each of the cold electrodes to the hot electrode, said circuits being inductively associated, and an antenna system associated with said circuits.

4. In a radio signaling system, an audion including hot and cold electrodes therein, said cold electrodes being located at relatively different distances from said hot electrode, separate circuits connecting each of said cold electrodes to said hot electrode, and means to set up successively increasing pulsations in said circuits, and an antenna system inductively associated with said circuits.

5. In a radio signaling system, an audion including hot and cold electrodes therein, said cold electrodes being located at relatively different distances from said hot electrode, separate oscillating circuits connecting each of the cold electrodes to said hot electrode, said circuits being inductively coupled and an antenna system inductively associated with said coupling.

6. In a radio signaling system, an evacuated vessel containing hot and cold electrodes therein, said cold electrodes being located at relatively different distances from said hot electrode, separate circuits connecting each of said cold electrodes with said hot electrode, said circuits being inductively associated, a source of electromotive force and a signaling device being included in one of said circuits.

7. In a radio signaling system, an evacuated vessel containing hot and cold electrodes therein, said cold electrodes being located at relatively different distances from said hot electrode, circuits connecting each of said cold electrodes with said hot electrode, said circuits being inductively coupled, a source of electromotive force and a signaling device being included in one of said circuits and an antenna system inductively associated with said coupling.

8. In a radio signaling system, an evacuated vessel containing hot and cold electrodes therein, said cold electrodes being located at relatively different distances from said hot electrode, circuits connecting each of said cold electrodes with said hot electrode, said circuits being associated, a source of electromotive force and a signal indicating device being included in one only of said circuits and an antenna system associated with said circuits, and means for operating said radio signaling system as a transmitting station.

9. In a radio signaling system, an evacuated vessel containing hot and cold electrodes therein, circuits connecting each of said cold electrodes with said hot electrode, said circuits being inductively associated, a source of electromotive force and a signal indicating device being included in one of said circuits and an antenna system associated with said circuits, and means for operating said signaling system as a receiving station.

10. In a radio signaling system, an audion including hot and cold electrodes therein, said cold electrodes being located at relatively different distances from said hot electrode, separate circuits connecting each of said cold electrodes to said hot electrode, said circuits being inductively associated with each other.

11. In a radio signaling system, an evacuated vessel containing a hot electrode and a plurality of grid electrodes and a plurality of wing electrodes, circuits connecting each of said grid electrodes and said wing electrodes with said hot electrode, the circuits of the grid electrodes being inductively associated with the circuits of the wing electrodes.

12. In a radio signaling system, an evacuated vessel containing a hot electrode and a plurality of grid electrodes and a plurality of wing electrodes, circuits connecting each of said grid electrodes and said wing electrodes with said hot electrode, the circuits of the grid electrodes being associated with the circuits of the wing electrodes respec-

tively, and a signal indicating device included in each of the circuits of said wing electrodes.

13. In a radio signaling system, an evacuated vessel containing a plurality of wing electrodes and a plurality of grid electrodes, a filament electrode interposed between said grid electrodes and between said wing electrodes, circuits connecting each of said wing and grid electrodes with said filament electrode, the circuits of said grid electrodes being inductively associated with the circuits of said wing electrodes respectively.

14. In a radio signaling system, an evacuated vessel, containing a plurality of wing electrodes and a plurality of grid electrodes, a filament electrode interposed between said grid electrodes and between said wing electrodes, circuits connecting each of said wing and grid electrodes with said filament electrode, the circuit of each of said grid electrodes being inductively associated with the circuit of said wing electrode on the opposite side of said filament electrode.

15. In a radio signaling system, an evacuated vessel containing a plurality of wing electrodes, and a plurality of grid electrodes, a filament electrode interposed between said grid electrodes and between said wing electrodes, circuits connecting each of said wing and grid electrodes with said filament electrode, the circuits of said grid electrodes being inductively coupled with the circuits of said wing electrodes respectively.

16. In a radio signaling system, an evacuated vessel containing a plurality of wing electrodes and a plurality of grid electrodes, a filament electrode interposed between said grid electrodes and between said wing electrodes, circuits connecting each of said wing and grid electrodes with said filament electrode, the circuits of said grid electrodes being inductively coupled with the circuits of said wing electrodes respectively, and an antenna system inductively associated with said coupling.

17. In a radio signaling system, an evacuated vessel containing a plurality of wing electrodes, and a plurality of grid electrodes, a filament electrode interposed between said grid electrodes and between said wing electrodes, circuits connecting each of said wing and grid electrodes with said filament electrode, the circuits of said grid electrodes being inductively coupled with the circuits of said wing electrodes respectively, the circuit of each of said grid electrodes being inductively coupled with the circuit of said wing electrode on the opposite side of said filament.

18. In a radio signaling system, an evacuated vessel containing a plurality of wing electrodes, and a plurality of grid electrodes, a filament electrode interposed between said grid electrodes and between said wing electrodes, circuits connecting each of said wing and grid electrodes with said filament electrode, the circuits of said grid electrodes being inductively coupled with the circuits of said wing electrodes respectively, the circuit of each of said grid electrodes being inductively coupled with the circuit of said wing electrode on the opposite side of said filament, and an antenna system inductively associated with each said coupling.

19. In a system for generating oscillations, a work circuit, and means for generating and transmitting the generated oscillations comprising an oscillatory circuit having two electrodes in an exhausted receptacle, and a second circuit inductively coupled thereto having a conducting body interposed between said electrodes.

20. In a system for generating oscillations, a work circuit, and means for generating and transmitting the generated oscillations comprising an oscillatory circuit having two electrodes, a second circuit inductively coupled thereto and having a conducting body interposed between said electrodes.

21. In a system for generating oscillations, a work circuit, and means for generating and transmitting the generated oscillations comprising an oscillatory circuit having two electrodes, a second circuit inductively coupled thereto and having a conducting body interposed between said electrodes and means for varying the frequency of the produced oscillations.

22. In a system for generating oscillations, a work circuit, and means for generating and transmitting the generated oscillations comprising an oscillatory circuit having two electrodes means for producing a flow of current between said electrodes and a second circuit inductively coupled with the first circuit and having a conducting body interposed between said electrodes.

23. In a system for generating oscillations, a work circuit, and means for generating and transmitting the generated oscillations comprising an oscillatory circuit having two electrodes means for producing a flow of current between said electrodes and a second oscillatory circuit inductively coupled with the first oscillatory circuit and having a conducting body interposed between said electrodes.

24. The method of generating alternating currents which consists in causing current to flow in one of two inductively coupled circuits, and varying the flow of current in the first circuit by impressing the potential induced in the second circuit upon a conducting body interposed between two electrodes in the first circuit.

25. Means for producing sustained electrical oscillations comprising an oscillatory circuit having two electrodes in an exhaust-

ed receptacle and a second circuit coupled thereto having a conducting body interposed between said electrodes.

26. Means for producing sustained electrical oscillations comprising an oscillatory circuit having two electrodes, a second circuit coupled thereto having a conducting body interposed between said electrodes, and means for varying the frequency of the produced oscillations.

27. Means for producing sustained electrical oscillations comprising an oscillatory circuit having two electrodes, means for producing a flow of current between said electrodes, and a second circuit coupled with the first having a conducting body interposed between said electrodes.

28. The method of producing electrical alternating currents which consists in causing current to flow in one of two coupled circuits and varying the flow of current in the first circuit by impressing the potential induced in the second circuit upon a conducting body interposed between two electrodes in the first circuit.

29. In a system for generating electrical oscillations, a work circuit, and means for generating and transmitting the generated oscillations to said work circuit comprising an evacuated vessel having a hot electrode, a cold plate electrode and a cold grid electrode, said cold electrodes being electrically associated with each other, and a source of current for the hot electrode.

30. The method of producing high frequency alternating currents, which consists in causing current to flow in one of two associated circuits and varying the flow of current in the first circuit by impressing a charge induced in the second circuit upon an element in the space between the electrodes respectively included in said second circuit.

31. Means for generating high frequency oscillations, including an evacuated vessel having separated wing, grid and filament electrodes therein, circuits for said electrodes, and a source of current supply having its terminals respectively connected to two of said electrodes and operating to generate oscillations in one of said electrode circuits.

32. The combination with a work circuit and means for generating and transmitting the generated alternating currents to said work circuit, comprising an evacuated vessel having a hot and a plurality of cold electrodes therein, said cold electrodes being located at relatively different distances from said hot electrode, means to supply current to said electrodes, and circuit connections between said electrodes.

33. The combination with a work circuit and means for generating and transmitting the generated alternating current to said work circuit, comprising an evacuated vessel having a hot and a plurality of cold electrodes therein, said cold electrodes being located at relatively different distances from said hot electrode, a circuit connection between the cold electrodes, and means for impressing an electromotive force in the space between the cold and hot electrodes, and means to supply current to the hot electrode.

34. The combination with a work circuit and means for generating and transmitting the generated alternating currents to said work circuit, comprising an evacuated vessel having a hot and a plurality of cold electrodes therein, said cold electrodes being located at relatively different distances from said hot electrode, a circuit connection between the cold electrodes, a circuit connection between one of the cold electrodes and one side of the hot electrode, a source of current included in said last-mentioned circuit connection, and means for supplying current to the hot electrode.

35. A work circuit and means for generating and transmitting the generated oscillations to said work circuit, comprising an audion and its associated circuits.

36. The combination with a work circuit and means for generating and transmitting the generated oscillations to said work circuit, comprising an evacuated vessel having filament, grid and plate electrodes therein, means to supply current to said electrodes, and circuit connections between said electrodes.

37. In a system for generating electrical oscillations, an evacuated vessel having a hot electrode, a cold plate electrode and a controlling electrode, circuits connected to said cold plate electrode and said controlling electrode, respectively, and coupled with each other, and a source of current for the hot electrode.

38. The combination with a translating device, of means for generating and transmitting to said device the generated oscillations, comprising an evacuated vessel having filament, grid and plate electrodes, means to supply current to said electrodes, and circuit connections between said electrodes.

39. Means for producing sustained electrical oscillations, comprising an oscillatory circuit having two electrodes, one of said electrodes comprising an incandescent filament, a second circuit coupled to said oscillatory circuit and having a controlling grid electrode for regulating the discharge between said two electrodes.

40. Means for producing electrical oscillations comprising an oscillatory circuit having two electrodes, one of said electrodes comprising an incandescent filament, a second circuit coupled thereto having a con-

trolling grid electrode associated with said electrodes, and means for varying the frequency of the produced oscillations.

41. The method of producing electrical oscillations with an incandescent filament thermionic discharge device having two coupled circuits each connected to the incandescent filament thereof, which consists in causing current to flow in one of the said two coupled circuits and varying the flow of current in said first circuit by impressing the potential induced in the second circuit upon a controlling grid electrode regulating the current flow in the first circuit.

In testimony whereof I have hereunto set my hand in the presence of a subscribing witness, on this 18th day of September, A. D., 1915.

UNITED STATES PATENT OFFICE.

LEE DE FOREST, OF NEW YORK, N. Y., ASSIGNOR TO RADIO TELEPHONE & TELEGRAPH COMPANY, A CORPORATION OF DELAWARE.

WIRELESS TELEGRAPH AND TELEPHONE SYSTEM.

Application filed March 20, 1914. Serial No. 825,984.

To all whom it may concern:

Be it known that I, LEE DE FOREST, a citizen of the United States, residing at New York, in the county and State of New York, have made a certain new and useful Invention in Wireless Telegraph and Telephone Systems, of which the following is a specification.

This invention relates to wireless telegraph and telephone systems.

The object of the invention is to provide a wireless telegraph and telephone system which is simple and efficient and wherein provision is made for duplex operation whether for telegraphing or telephoning.

A further object is to provide a more perfect generator of high frequency oscillations of uniform amplitude.

A further object is to provide a system of the nature referred to employing an oscillation generator which combines detector functions with its functions as a generator and to utilize the combined functions thereof for duplex operation.

Other objects will appear more fully hereinafter.

The invention consists substantially in the construction, combination, location and relative arrangements of parts all as will be more fully hereinafter set forth, as shown in the accompanying drawings, and finally pointed out in the appended claims.

Referring to the drawings,—

Fig. 1 is a circuit diagram showing one arrangement embodying my invention wherein the device serves as a generator of continuous oscillations.

Fig. 2 is a circuit diagram showing an arrangement whereby the receiver is not affected by the energy being radiated from the home antenna.

Fig. 3 is a circuit diagram showing an arrangement wherein the same device serves as an oscillation generator and a detector.

Fig. 4 is a similar view showing a modified arrangement wherein a detector separate from the oscillation generator is employed.

Fig. 5 is a similar view of a modified form of detector employed in accordance with my invention.

In the drawing N designates the antenna for transmitting and receiving. Adjustably connected in the antenna circuit is an inductance S. The antenna circuit is connected to earth or other capacity E, and, where the apparatus is to be used for telephonic communication the antenna includes a microphone transmitter M. Where the apparatus is to be used for telegraphing a Morse telegraph key K is bridged across a portion of the inductance S. The inductance S is in the form of a coil with which is inductively associated, preferably in loose coupled relation, an inductance coil P, one terminal of which is connected to auxiliary or cold grid electrodes G, G, arranged within an evacuated bulb or vessel U. The other terminal of coil P is connected to the cold plates or electrodes W also arranged within the bulb U. Connected across the terminals of coil P is a variable capacity C_1. In series with the coil P and electrodes G, I place a blocking condenser C_3, and if desired, (see Fig. 3), in series with the coil P and electrode plates W, I place an inductance coil L, across the terminals of which is connected a variable capacity C_2. Contained in the bulb U is a hot electrode F, which is, in the form shown, a filament or glower, to which current is supplied from any convenient source indicated at A, the current supply being regulated by a rheostat R.

As above indicated the current source A may be of any desired form, such for instance as a battery, direct current generator, or an alternating current generator. Where an alternating current generator is employed, as indicated in Fig. 5, the frequency, for wireless telephone operation, should be above that of the essential frequencies of voice sounds, say fifteen hundred cycles per second, or higher. For wireless telegraph work the frequency of the generator may be very much lower, for example, five hundred per second.

A telephone receiver T is connected on one side in series with the plate electrodes W, and on the other side in series with the filament F. In circuit with the telephone T, is a source of current supply indicated at B, as a battery, the purpose of which is to impress an electro-motive-force between the cold plate electrodes W, and the filament F.

By reason of the arrangement above de-

scribed the device U with its associated electrodes and filaments and their associated circuits and connections, becomes a generator of alternating or pulsating electric currents or continuous oscillations of high frequency in the circuit of coil P, the frequency of which depends upon the spatial relation of the electrode members contained therein, the value of the electro motive force impressed across the electrodes, and the amount of inductance and capacity included in or associated with the circuit of said coil. In the arrangement shown in Fig. 3 the frequency of such oscillations may be varied by varying the capacity of condensers C_1 or C_2.

By reason of the relation of coils P and S, the oscillations in the circuit of coil P are impressed upon the antenna-earth system and with a natural period of oscillation in the antenna-earth system the same as that of the oscillations in the circuit of primary coil P.

The amplitude of the oscillations induced in the antenna earth system as above described may be varied by and in accordance with sound waves falling upon the microphone transmitter M, in the usual manner. Similarly, a telegraph key associated in the antenna earth system may serve to control the emission of wave trains in accordance with the telegraphic code, if desired, and as shown, if the key K is associated with the antenna-earth system in such a manner as to short circuit a portion of the inductance S, the wave length of the emitted wave trains may be altered in a manner well understood in the art.

It will be seen that, in the arrangement shown in Fig. 3, the device U, with its associated electrodes and filament and circuit arrangement therefore combines within itself the functions of a source of continuous oscillations and also those of a detector, like the audion detector, and its detector functions are in no way impaired by its simultaneous operation as an oscillation generator. Incoming electro-magnetic signals influence the circuits of the electrodes G and W, and produce an alteration in the conducting qualities of the medium between the plate and grid electrodes, and consequently any received signals when attuned to the proper wave length will be heard in the receiver T, during the pauses between the signals being made by the operation of the key K, or between the words spoken into the microphone transmitter M. By this simple arrangement, as described, I am enabled to secure duplex operation whether for telegraphing or telephoning, employing the same apparatus for transmitting and receiving.

It is obvious that provision may be made to protect the telephone receiver T in case large amounts of current are to pass across the space in the bulb U. Any suitable means may be employed for this purpose, as, for instance the usual high resistance telephone receiver may be employed, which, if desired, may be coupled to the circuit containing the battery B, electrodes W and filament F, in any suitable or well known manner.

In Fig. 4 I have shown an arrangement wherein a detector device independent of and separate from the oscillation generator is employed. In this arrangement I employ for the detector an evacuated bulb U_2 with a filament F_2, and a grid G_2 and a plate W_2 similar to corresponding parts above described with reference to bulb U, the filament circuit being supplied with current from a current source A_2, controlled by a rheostat R_2, the plate W_2 constituting one terminal of a circuit which contains the telephone receiver T_2 and current source B_2, the other terminal of said circuit being connected to one side of the filament circuit. One terminal of another circuit is connected to the grid G_2, the other terminal of said circuit being connected to the other side of the filament F_2. This last mentioned circuit is inductively associated with the oscillating circuit which contains the coil P, as for instance, through the coils L_1 L_2, the latter being shunted by a variable capacity C_2. By means of the variable condenser C_2 this secondary system can be accurately attuned to the frequency of the received oscillations. It is obvious that this secondary receiver circuit may be associated with the antenna earth system, or with the circuit of coil P, in any other suitable or well known manner.

Any suitable means may be employed to supply the necessary inertia to the circuit of battery B, such, for instance, as by including an impedance coil I, in said circuit.

Fig. 2 shows a "balanced antenna circuit" associated with the source of the oscillations S, and its inductances and capacity so proportioned relative to the capacity of the antenna itself that the total effect of the oscillations from the source S upon the receiver transformer L_1 L_2 is neutralized while at the same time impulses received on the antenna N, preferably of a slightly different frequency from that of the oscillations from S, are clearly received in the properly attuned receiving circuit L_2 C_3 and transmitted to the audion detector U and translated there into telephone currents in the circuit T B in the well known manner.

I am unable at the present time to give a complete explanation of the theory of action of the apparatus when operating as a generator. I have discovered, however, as hereinabove stated, that a system constructed as shown and described and energized from a suitable current source, becomes the seat of continuous high frequency oscilla-

tions. Undoubtedly the phenomena involved depends upon the effect of successively applied charges or surges of potential upon the grid and plate elements and having the power to effect momentarily the conductivity of the medium between the filament and plate electrodes in such manner that the current variations in the grid filament circuit produce corresponding variations in the plate filament circuit which are fed back to the grid filament circuit to add their effects to the initial variations, which latter, thus reinforced, create and form greater variations in the plate filament circuit which are, in turn, fed back to the grid filament circuit to still further amplify the variations in that circuit, and so on. The energy of the variations of each circuit reacts upon and increases that of the other circuit until a maximum sustained alternating current is finally produced, whose frequency can be controlled by varying the electrical constants of the associated circuits. In other words, the amplifying action incident to the feeding back of energy from the one circuit to the other increases until oscillations are produced which, once set up are self-perpetuating, analogous to the "whistling" or surging action observed when a telephone receiver and microphone transmitter, connected together in the same or coupled circuits, are so placed as to react one on the other mechanically and electrically.

From the foregoing description it will be observed that in its broad scope my invention lies in the discovery that when suitably connected and associated an audion becomes a generator of oscillating, alternating or pulsating electric currents which may be utilized for any purpose for which such currents are desired, and I have succeeded in securing remarkable results in the practical use and operation of an oscillation generator of this character particularly when applied to the generator of high frequency oscillations.

It is obvious that the principles of my invention may be embodied in various other arrangements, and that various changes in the details might readily occur to those skilled in the art, and still fall within the spirit and scope of my invention.

But having now set forth the objects and nature of my invention, and arrangements embodying the principles thereof, what I claim as new and useful, and of my own invention, and desire to secure by Letters Patent, is,—

1. In a system for generating electrical oscillations, a work circuit, and means for generating and transmitting the generated oscillations to said work circuit comprising an evacuated vessel having a hot electrode, a cold plate electrode and a cold grid electrode, an oscillating circuit, one side of said circuit being connected to the grid electrode and the other side to the plate electrode, and means for impressing an electromotive force in the space between the hot electrode and the plate electrode.

2. In a system for generating electrical oscillations, a work circuit, and means for generating and transmitting the generated oscillations to said work circuit comprising an evacuated vessel having a hot electrode, a cold plate electrode and a cold grid electrode, interposed between the hot and cold plate electrode, a source of current for the hot electrode, an oscillating circuit connecting said cold electrodes, and means for impressing an electromotive force between said hot electrode and said cold plate electrode.

3. In a system for generating electrical oscillations a work circuit, and means for generating and transmitting the generated oscillations to said work circuit including an evacuated vessel having hot and cold electrodes therein, circuits for said electrodes, one of said circuits being a series oscillating circuit and connected between said cold electrodes, and means for impressing an electromotive force in the space between two of said electrodes.

4. In a system for generating electrical oscillations a work circuit, and means for generating and transmitting the generated oscillations to said work circuit including an evacuated vessel having hot and cold electrodes therein, circuits for said electrodes, one of said circuits being a series oscillating circuit and connected between said cold electrodes, means for impressing an electromotive force in the space between two of said electrodes, and a telephone associated with one of said circuits.

5. Means for producing high frequency oscillations for transmission comprising a transmitting circuit associated therewith, an oscillatory circuit having two cold electrodes in an exhausted receptacle and a second circuit having a conducting electrode within said receptacle, one of said oscillating circuit electrodes being interposed between the other two, and means for impressing an electromotive force between one of said cold electrodes and said conducting electrode.

6. Means for producing high frequency oscillations for transmission comprising a transmitting circuit associated therewith, an oscillatory circuit having two cold electrodes, a conducting electrode, one of said cold electrodes being interposed between the other two, a circuit connection between the conducting and one of the cold electrodes, and means for varying the frequency of the produced oscillations.

7. Means for producing high frequency oscillations for transmission comprising a transmitting circuit associated therewith, an oscillatory circuit having two cold elec-

trodes a second circuit including a current source and a conducting electrode one of said cold electrodes being interposed between the other two electrodes and means for controlling flow of current through the space between said electrodes.

7. Means for generating high frequency oscillations for transmission including a transmitting circuit associated therewith, an evacuated vessel containing hot and cold electrodes, and a series oscillation circuit connecting said cold electrodes and a source of power associated with said circuit.

8. Means for generating high frequency oscillations for transmission including an evacuated vessel, a circuit including a transmitting circuit associated therewith, a current source and having its terminals within and sealed and separated from each other, and an oscillatory circuit including a conducting body interposed between said terminals.

10. The combination with a work circuit, and means for generating and transmitting the generated alternating currents to said work circuit, comprising an evacuated vessel having a hot and a plurality of cold electrodes therein, said cold electrodes being located at relatively different distances from said hot electrode, inductance and capacity connected between the cold electrodes, means for impressing electro-motive force in the space between one of the cold electrodes and the hot electrode, and means for supplying current to the hot electrode.

11. The combination with a work circuit, and means for generating and transmitting the generated alternating currents to said work circuit, comprising an evacuated vessel having a hot and a plurality of cold electrodes therein, said cold electrodes being located at relatively different distances from said hot electrode, an oscillating circuit connecting the cold electrodes, means for impressing an electro-motive force in the space between the cold and hot electrodes and means for supplying current to the hot electrode.

12. An audion having a plurality of grid electrodes, a plurality of wing electrodes, a hot electrode, a series oscillating circuit associated with the grid and wing electrodes, and means for impressing an electro-motive force between the wing and hot electrodes.

13. In a radio signaling system an evacuated vessel having separate electrodes therein, and circuit connections [illegible] to constitute a combined generator of high frequency oscillations and detector of high frequency oscillations.

14. In a radio signaling system an evacuated vessel having separate electrodes therein, and circuit connections [illegible] to constitute a combined generator of high frequency oscillations and a detector for received high frequency oscillations, and an antenna system associated therewith.

15. In a radio signaling system, an evacuated vessel including hot and cold electrodes therein, said cold electrodes being located at relatively different distances from said hot electrodes, circuits connecting each of said cold electrodes to said hot electrode, and means to set up successively increasing potentials in said circuits.

16. In a radio signaling system, an evacuated vessel containing hot and cold electrodes therein, circuits connecting each said cold electrode with said hot electrode, said circuits being associated, a source of electro-motive force, and a signal indicating device being included in said circuits, and an antenna system associated with said circuits, and means for operating said signaling system as either a transmitting or a receiving system.

17. In a radio signaling system, an audion including hot and cold electrodes therein, said cold electrodes being located at relatively different distances from said hot electrodes, circuits connecting each of said cold electrodes to said hot electrode, and means to cause said circuits to react upon each other.

18. In a radio signaling system, an audion including hot and cold electrodes therein, said cold electrodes being located at relatively different distances from said hot electrodes, circuits connecting each of said cold electrodes to said hot electrode, said circuits being associated to react upon each other.

19. In an electrical system, an evacuated vessel, hot and cold grid and plate electrodes therein, a circuit connecting each of said cold electrodes with said hot electrode, said circuits being associated to react upon one another.

20. In an electrical system, an evacuated vessel, a hot electrode within said vessel, cold grid and plate electrodes associated therewith, a circuit connecting each of said cold electrodes with said hot electrode, said circuits and electrodes being so associated that electrical variations in either circuit produce electrical variation in the other circuit.

21. In an electrical system, an audion including a hot electrode, a plate electrode and controlling electrodes, circuits connecting the plate electrode and controlling electrode with said hot electrode, and means for causing variations in the circuit of the plate electrode to react upon the controlling electrode.

In testimony whereof I have hereunto set my hand in the presence of the subscribing witnesses, on this 10th day of March A. D. 1914.

[fol. 3751] IN THE SUPREME COURT OF THE UNITED STATES,
OCTOBER TERM, 1942

No. 369

STIPULATION—Filed Jan. 5, 1943

It is hereby stipulated and agreed by and between counsel for the respective parties herein, subject to the approval of the Court, as follows:

(1) That the following and only the following exhibits shall be printed or reproduced for use on the argument of the above-entitled cause:

Plaintiff's exhibits: Nos. 7; 19; 20; 21; 22; 34; 35; 36; 46; 53; 59; 60; 69; 72; 74; 75; 77; 78 (1913 edition; Figs. 29a, 31, 33, 62, and 89; 1915 edition: Figs. 84 and 88); 79; 80; 84; 87; 91 (Figs. 36 and 37); 92 (Figs. 1, 3, 4, 6, 9, and 61; and page 110); 95; 99; 102; 103; 106; 107; 108; 109; 110; 111; 112; 113; 114; 116; 120′ (Interdepartmental Radio Board Preliminary Report); 120″ (Stone Canadian Society Lecture); 121′ (Stone U. S. Patent No. 767,984); 121″ (Interdepartmental Radio Board's Letter of April 16, 1921); 122; 142; 150; 151; 157; 158; 159; 160; 171; 203 (Fig. 45); 205 (Fig. 218; 211; 223; 225; 227; 228; 229; 230; 241; 242; 243; 244; 246; 248 (Figs. 2, 3, 4, and 5); 250; [fol. 3752] 258; 259; 260; 261; 262; 263; 264; 265; 266; 268; 269; 270; 273; 274; 275; 276; 282; 287; 289; 290; 298; 300; 301; 302; 315; 317; 318; 319; 322; 323; 324; 325; 326; 327; 335; 343; 344; 347; 348; 349; 363; 364; Waterman's Drawings Nos. 1, 2 and 3; 410; 413A; 419; 420; 440; 441; 453; 454; 455; 462; 472; 477A. (Note that 477A is the same as part of the April 6, 1942 findings of the Court of Claims and appears at page 142 of the printed record.)

Defendant's exhibits: Nos. A; B; C; D; I; J; K; L; M; N; O; P; S; T; U; V; W; X; Z; A-1; B-1; C-1; D-1; E-1; F-1; G-1; H-1; I-1; J-1; K-1; L-1; M-1; N-1; P-1; T-1; A-2; B-2; C-2; E-2; F-2; M-2; O-2; P-2; Q-2; R-2; U-2; V-2; W-2; X-2; Y-2; Z-2; A-3; B-3; D-3; E-3; F-3; G-3; H-3; I-3; K-3; N-3; P-3; Q-3; R-3; B-4; E-4; J-4; R-4; S-4; Z-4; A-5; B-5; C-5; D-5; E-5; F-5; G-5; N-5; O-5; Q-5; S-5; T-5; U-5; V-5; W-5; X-5; B-6; L-6; M-6; N-6; Q-6; S-6; V-6; W-6; Y-6; Z-6; JJ; KK; LL; MM; PP; BBB and UUU. (As to KK, it will be sufficient to note

that it is the same as Defendant's Exhibit U-2 to be reproduced. As to LL, Fessenden patent 706,735, it will be sufficient to reproduce it as part of Plaintiff's Exhibit 171 and note that LL is the same as such part of Exhibit 171.

(2) Whereas, through inadvertence, page 73 of plaintiff's exhibit No. 92 was included in the transcript of record certified to this Court from the Court of Claims herein instead of page 75 thereof, it is farther stipulated and agreed that the annexed copy of Fig. 62 of said exhibit (the same being a part of said page 75) shall be reproduced as a part of the record herein in lieu of Fig. 60 (which was a part of the erroneously-included page 73 of the said exhibit); and it is further stipulated and agreed [fol. 3753] that said Fig. 62 of said exhibit was a part of the printed record that was before the Court of Claims herein, and that certification thereof is therefore hereby waived.

Dated: December 31, 1942.

Richard A. Ford, Abel E. Blacknar, Jr., Counsel for Petitioner. Charles Fahy, Solicitor General of the United States. Clifton V. Edwards, Special Assistant to the Attorney General.

[fol. 4133] IN THE SUPREME COURT OF THE UNITED STATES,
OCTOBER TERM, 1942

No. 369

MARCONI WIRELESS TELEGRAPH COMPANY OF AMERICA

v.

UNITED STATES

STIPULATION AND ADDITION TO RECORD—Filed March 29, 1943

It is hereby stipulated between the respective parties by their attorneys, this Honorable Court consenting, that the attached reproduction of Defendant's Exhibit P-1 is a true copy of the said translation as it appeared in the printed record in the Court of Claims proceedings as to which certiorari has been granted, the illustrations in said attached reproduction having been inadvertently omitted in the transcript of record certified to this Court.

It is stipulated that the attached copy may be considered with like force and effect as though it were included in the printed transcript at the place designated, and that copies of said attached translation including the drawings may be substituted in lieu of the copy of said translation now appearing in Volume V, pages 3515-3518.

Dated March 23, 1943.

Abel E. Blacknar, Jr., Counsel for Petitioner.
Charles Fahy, Solicitor General of the United States.

1 DEFENDANT'S EXHIBIT P 1

(Translation of Defendant's Exhibit O-1). Physikalische Zeitschrift--Oct. 20, 1904, pp. 680-81. [1]Translation of Wehnelt article.

A Wehnelt (Erlangen), in Reference to the exit of Negative Ions from Incandescing Metallic Oxids and Phenomena Connected Therewith"

In a treatise with the same heading in Vol. 14, pp. 425–468 of the Annalen der Physik (1904) I have set forth a series of experiments and measurements which showed that certain metallic oxids, and in fact, especially the oxids of the earth alkali metals in an incandescing state, both under atmospheric pressure and also in a vacuum, emit numerous negative ions. (electrons)

[1] Read in Division 2 on the 21st of Sept. Exhaustive literary references are to be found in Annalen der Physik Vol. 14, p. 425 etc. 1904.

[1a] Vorgetragen in Abteilung 2 am 21 Sept. Ausführliche Litteraturangaben befinden sich Annalen der Physik 14, 425 etc. 1904.

In intimate connection with this quality stands the fact also discovered by me, that the cathode drop in a glimmer charge completely disappears on glowing oxid cathodes even under the deepest pressures, provided that the current density (current strength per square centimeter of incandescing oxid surface) remains below a value depending upon the temperature and increasing with this. That current density at which a cathode drop begins to show I have called the limit current density. It attains, under high incandescence of the oxid, values up to three amperes.

I wish today to first bring before you some experiments which explain that which has been said above, and then to show you a practical application of incandescing oxid cathodes.

Emission of Negative Ions by Incandescing Metallic Oxids.—A glass tube R (Fig. 1), exhausted to a moderate extent contains a brass cylinder C in the axis of which there is situated a thin platinum wire D covered with CaO. The wire can be heated to high temperatures by the current of two accumulators A. If I connect the wire D with the one pole, the cylinder C through a galvanometer G with the other pole, of a source of current B, then there only flows a current through the tube if D is connected with the negative pole of B. The experiment shows consequently that only negative ions are emitted from the incandescing oxid.

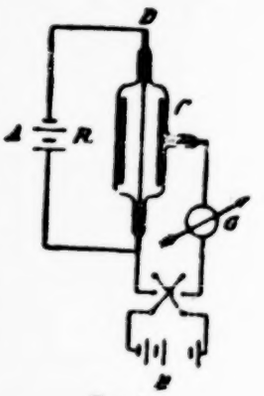

FIG. 1.

If I take another tube, which is otherwise exactly similar, but which contains a platinum wire carefully cleaned, and heat the same to the same temperature as previously the wire covered with CaO, then the current is under an equally high negative charge of the wire only exceedingly weak, and in fact, only about 1/1000 of that in the former experiment.

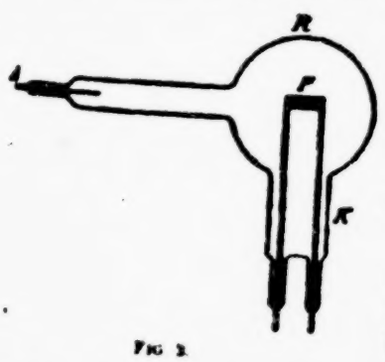

FIG. 2.

Incandescing Metallic Oxids as Cathodes in Discharge Tubes.—The tube R (Fig. 2) contains as cathode K a platinum sheet P covered with CaO which can be electrically heated red hot, and as an anode an iron wire A. The surface of the incandescing metallic used cathode amounting to several square centimeters, allows of sending through the tube considerable current strengths, even under deep pressures without there being present a cathode drop.

Since the anode drop constantly amounts to about 20 volts and the drop on the positive cells under strong currents and low pressures, as special measurements have shown, amounts to only one to two volts per centimeter, I can, by using the light conductor of

220 volts potential, send through the tube (Fig. 2) currents of several amperes strength. The incandescing oxid cathodes furnish us consequently with a means of investigating the processes in the positive column with any gas whatever and under any pressures however deep, up to very high current strengths. The remarkable brightness of the positive strata under high current strength promises to be serviceable to the spectro-analytical investigation of gas spectra. Quartz windows on the tube would also make the ultra violet portion of the light of the strata accessible to investigation.

3

Weak Cathode Rays.—If we exceed the limit current density either by increasing the current strength or decreasing the temperature of the incandescing oxid cathode, then we can impart to the cathode drop any desired value, and consequently produce cathode rays of any desired velocity.

The tube, Fig. 3, contains as cathode K a small platinum sheet P upon which there is located a small speck of calcium oxid.

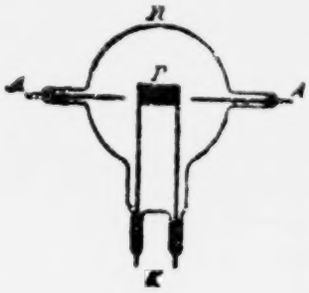

FIG. 3

A brass rod A serves as anode. If the sheet P is electrically brought to a glowing heat and the electrodes A, K, by throwing in a suitable resistance are connected with the light conductor of 220 volts potential, then the entire current goes only through the calcium oxid coating on the cathode sheet P, since here the cathode drop is much lower than on the clean platinum sheet, whereby there proceeds an intensely blue cathode beam of rays from the coating. By changing the temperature of the platinum sheet, there can be imparted to the cathode rays then any desired velocity, and this can then be measured according to well-known methods.

Application of Discharge Tubes with Glowing Metal Oxid Cathodes in Practice.—If in an exhausted discharge tube R (Fig. 4[1]) we push one or several metallic electrodes A close to the glowing metallic oxid electrode K (platinum sheet P covered with CaO) then the discharge potential, if A is anode and K is cathode, amounts to only about twenty volts. If we reverse the direction of current so that now A is cathode and K is anode, the discharge potential now amounts to some thousands of volts, since under deep pressures the cathode drop on metals takes on exceedingly high values. If, therefore, we connect the electrodes A and K with an alternating source of current, the potential of which lies below the value which the cathode drop on the metallic electrode A has, then the tube acts as an electric valve, in that it allows to pass through only one phase of the alternating current. The tube (Fig. 4) can consequently serve for the purpose of transforming alternating current into pulsating direct current.

4

[1] The cathode K is assumed to be turned 90° as regards the plane of the picture.

The maximum current strength to be sent through the tube (valve ...e depends as follows, from what has been said above, upon the ... of the glowing oxid surface. The efficiency of the valve tube ...ends upon the working potential employed, and ... rases with this, since the tube up to the strongest ...wable current strength, entirely independent of ... absorbs always only 20 volts potential. In ...plying a working potential of 120 volts alternating ...rent, taking into consideration the consumption ... watts for heating of the metal oxid cathode, the ...ciency of the valve tube amounted to about 65%. By using the well-known Graetz system of con... both phases of the alternating current can ...tilized. By using three metallic anodes, we ... as with a Hewitt transformer, also transform rotary current into ...ating direct current.

Petition for writ of certiorari	1
I. Summary statement of matter involved	2
II. The questions presented	7
III. Reasons relied on for the allowance of the writ of certiorari	7
Brief in support of petition	10
Opinions of the court below	10
Jurisdiction	10
Statement of the case	11
Specification of errors	12
Summary of argument	14
Argument	14
Point I. The Court of Claims, in holding that claims 1, 2, 3, 6, 8, 10 to 14, and 17 to 20 of Marconi patent No. 763,772 were invalid, has rendered a decision in conflict with the decisions of the Circuit Court of Appeals for the Ninth Circuit and the United States District Courts for the District of Washington and for the Eastern District of New York, on the same question and on substantially the same evidence, in Marconi Wireless Telegraph Company of America v. Kilbourne & Clark Manufacturing Co. (265 Fed. 644, affirming the decision of the Washington District Court, 239 Fed. 328), and in Marconi Wireless Telegraph Company of America v. National Electric Signalling Co. (273 Fed. 813), respectively	14
Point II.—The Court of Claims, in holding that claims 1 and 37 of Fleming patent No. 803,684 were not infringed, and in failing to hold that these claims were valid, has rendered a decision in conflict with the decision, rendered on the same questions and on substantially the same evidence, of the Circuit Court of Appeals for	

Page

the Second Circuit, in Marconi Wireless Telegraph Company of America v. DeForest Radio Telephone & Telegraph Co. (243 Fed. 560, affirming 236 Fed. 942), and the two subsequent decisions of the United States District Court for the Southern District of New York in the same case (memorandum opinion of July 11, 1917, not reported, and 261 Fed. 393) 21

Point III. The Court of Claims, in limiting petitioner's compensation, for the use by respondent of upwards of $40,000,000 worth of radio apparatus during the accounting period, to less than $80,000 plus additional compensation measured by interest), has rendered a decision which, in view of the prior recognized fundamental position of petitioner's patents in the radio art and in view of the proposed award to petitioner by the Interdepartmental Radio Board of upwards of $1,250,000, has resulted in a failure of justice as between the United States and one of its citizens 26

Point IV. The Marconi patent No. 763,772 was valid as to claims 1, 2, 3, 6, 8, 10 to 14, and 17 to 20 thereof, and the subject matter of said claims was used by respondent 27

A. Said claims of the patent were valid 27

B. The above-mentioned claims of the Marconi patent were infringed 29

Point V. The Fleming patent No. 803,684 was valid as to claims 1 and 37 thereof and the subject matter of said claims was used by respondent 30

A. The patent was infringed 30

B. The Fleming patent was valid 32

SUPREME COURT OF THE UNITED STATES
OCTOBER TERM, 1942

No. 369

MARCONI WIRELESS TELEGRAPH COMPANY OF AMERICA,

Petitioner,

vs.

THE UNITED STATES.

PETITION FOR WRIT OF CERTIORARI TO THE COURT OF CLAIMS.

To the Honorable the Chief Justice and Associate Justices of the Supreme Court of the United States:

Your petitioner, Marconi Wireless Telegraph Company of America, respectfully prays for a writ of certiorari, directed to the Court of Claims of the United States, to review the interlocutory and final judgments of that court rendered in this action on November 4, 1935,[1] and April 6, 1942,[2] respectively. The transcript of record in the case is being filed herewith in accordance with Rule 41 of this Court.[3]

[1] Findings and opinion reported in 81 C. Cls. 671.

[2] Not yet reported. The Findings of Fact, Conclusion of Law, and Opinion of the Court will be found at Court R., pp. 117-182.

[3] The record, as filed in this Court, includes a portion ("Other parts" R., pp. 2313-2522) which was included at respondent's request. This portion of the record is not material to the issues raised by this petition; it will be material to the case only in the event that respondent files a petition with respect to the Findings of the court below that claim 16 of Marconi patent No. 763,772 was valid and infringed.

I.

Summary Statement of Matter Involved.

Petitioner, at the time of instituting the present action, was the owner, among many other United States Letters Patent, of a reissued patent to Guglielmo Marconi, No. 11,913, the original of which had issued July 13, 1897; a patent to Sir Oliver Lodge, No. 609,154, which issued August 16, 1898; another patent to Marconi, No. 763,772, which issued June 28, 1904; and a patent to Sir John Ambrose Fleming, No. 803,684, which issued November 7, 1905. Each of these patents covered inventions in the then infant field of wireless or radio communication.

This action was brought by petitioner in the Court of Claims of the United States under the Act of Congress of June 25, 1910[4] (U. S. Code, Title 35, Section 68), to recover compensation for the use, by the respondent, the United States, of apparatus embodying the subject matter of one or more of the four patents above-mentioned. The original petition, filed July 29, 1916, claimed compensation in the sum of $1,000,000.

On July 1, 1918, the Act of June 25, 1910, was amended to permit the recovery of compensation where the subject matter of a patent had been used *or manufactured* by *or for* the United States; the amendment also took away the patent owner's right to seek compensation from parties who supplied the Government with infringing apparatus. Thereafter, the patentee's sole remedy was by suit against the United States in the Court of Claims for the recovery of his reasonable and entire compensation. *Richmond Screw Anchor Co.* v. *United States*, 275 U. S. 331, 343. In view of the changes in the statute and of the greatly increased use of wireless apparatus by the respondent as a result of

[4] Printed, as amended July 1, 1918, at page 37, *infra*, as Appendix A.

the World War of 1916-1918, petitioner filed, on May 21, 1919, a Supplemental Petition (Court R., pp. 1-6) claiming $5,000,000 additional compensation. The period covered by the claim extends from July 29, 1910, to the dates of expiration of the Marconi reissue and Lodge patents, and, as to the other two patents, to November 20, 1919, the date when petitioner assigned the patents to a third party, the claim against respondent being, however, reserved to petitioner.

The subject matter of the Marconi reissue patent (Plaintiff's Exhibit 19, included in exhibits certified as incorporated by reference in the 1935 findings of the court below; offered "Other parts" R. p. 190), as petitioner considered that it should be construed, was an elevated aerial or antenna for radio communication, one end of which was connected to the earth, or "grounded". The subject matter of the Lodge patent (Plaintiff's Exhibit 20, included in the exhibits incorporated in the findings of the court below; offered "Other parts" R. p. 190) was the insertion in the antenna circuit, of a radio transmitter or receiver or both, of an inductance coil (coil of wire) for the purpose of "tuning" the antenna circuit • • • *i. e.*, making it selectively responsive to a particular, desired wavelength or frequency. The subject matter of the second Marconi patent, No. 763,772 (Plaintiff's Exhibit 21, included in the exhibits incorporated in the findings of the court below; offered "Other parts" R. p. 190-1) was the utilization, at a radio transmitting or receiving station or both, of two circuits (one an "open" or antenna circuit, and the other a "closed" circuit), the two circuits being coupled to each other and both of them being tuned to the same wavelength or frequency. The subject matter of the Fleming patent (Plaintiff's Exhibit 22, included in the exhibits incorporated in the findings of the court below; offered "Other parts" R. p. 191) was a vacuum tube ("valve") for use with

radio, the tube containing a filament ("cathode"), adapted to be heated to incandescence, and another electrode or element ("cold" electrode or "plate"), the filament and plate being connected together by a circuit outside of the tube.[5]

Copies of the Marconi patent No. 763,772 and of the Fleming patent are annexed hereto for the convenience of the Court.

The four patents upon which petitioner's claim was based were the fundamental patents of the radio art and it was upon their disclosures that substantially all of the subsequent marvelous development of that art has been built.[6]

The Marconi reissue patent had been sustained by the District Courts for the Eastern and Southern Districts of New York.[7] The Court of Claims held that it had not been infringed (Court R. p. 117).

The Lodge patent has been sustained by all courts which have passed upon it, including the court below. The Court of Claims held that it was valid and infringed (Court R. p. 117) and has awarded to petitioner, for respondent's use of the subject matter thereof from March 8, 1913, to August 16, 1915, compensation amounting to $34,827.70 (plus additional compensation measured by interest) (Court R. p. 135).

The Marconi patent No. 763,772 had been held valid and infringed by the District Court for the Eastern District of

[5] This is the "Fleming valve" which was several times referred to by this Court in *DeForest Radio Co. v. General Electric Co.*, 283 U. S. 664. See, for example, this Court's references to "Fleming, the inventor of the Fleming valve" and to the Fleming patent above referred to, at page 680 of 283 U. S.

[6] Respondent's Interdepartmental Radio Board recognized that all four of these patents were fundamental (see brief, p. 12 *infra*).

[7] *Marconi Wireless Telegraph Co. of America* v. *National Electric Signalling Co.* 213 Fed. 815; *Same* v. *DeForest Co.*, 138 Fed. 657.

New York;[8] it had also been held valid, but not infringed, by the District Court for the District of Washington in a decision which was affirmed by the Circuit Court of Appeals for the Ninth Circuit.[9] Both of these decisions were rendered after strenuously contested trials, most of the testimony, in the latter case at least, having been taken in open court. The corresponding British Marconi patent had been twice sustained by the High Court of Justice, Chancery Division;[10] and the corresponding French patent had been sustained by the Civil Tribunal of the Seine.[11] The Court of Claims, however, on testimony taken before an Examiner, held that all claims in issue of the patent were invalid, except claim 16 (a very limited claim) which was held valid and infringed (Court R. p. 117).[12]

The Fleming patent had been held valid and infringed, after a strenuously contested trial in open court, by the District Court for the Southern District of New York, in a decision which was affirmed by the Circuit Court of Appeals for the Second Circuit.[13] The District Court also held, on a

[8] *Marconi Wireless Telegraph Co. of America* v. *National Electric Signalling Co.*, 213 Fed. 815. No appeal was taken, the defendant taking a license (Plaintiff's Exhibit 360, included in exhibits incorporated in the findings of the court below; offered "Other parts" R., p. 2101).

[9] *Marconi Wireless Telegraph Co. of America* v. *Kilbourne & Clark Mfg. Co.*, 265 Fed. 644, affirming 239 Fed. 328; decree, Pltf's Exh. 364 ("Other parts" R., pp. 2500-3, offered "Other parts" R., p. 2103).

[10] *Marconi* v. *British Radio Tel. & Tel. Co.*, (1911) 27 T. L. R. 274, 28 R. P. C. 181; the Judgment is Plaintiff's Exhibit 7 ("Other parts" R., pp. 1600-1640; offered "Other parts" R., p. 186). *Marconi* v. *Helsby Wireless Telegraph Co.*, (1914) 30 T. L. R. 688; 31 R. P. C. 399; the Judgment is Plaintiff's Exhibit 35 ("Other parts" R., pp. 1642-7; offered "Other parts" R., p. 202).

[11] *Societe Marconi* v. *Societe Generale, etc.*, Pltf's Exh. 36 ("Other parts" R., pp. 1648-1708; offered "Other parts" R., p. 202).

[12] Commissioner Johns, who reported on the issues of validity and infringement of petitioner's patents, had heard none of the testimony.

[13] *Marconi Wireless Telegraph Co. of America* v. *DeForest Radio Tel. & Tel. Co.*, 243 Fed. 560 affirming 236 Fed. 942.

contested motion to extend the decree, that certain additional apparatus infringed the Fleming patent (Pltf's Exh. 171; "Other parts" R. pp. 2104-5; offered "Other parts" R. p. 1346); and, after a trial in open court on Supplemental Bill, that still other apparatus also infringed the patent (261 Fed. 393). The Court of Claims, on testimony taken before an Examiner,[4] held that the patent had not been infringed, and indicated, in its opinion, that it considered the patent invalid (although not actually holding it invalid). (Court R. pp. 117, 165).

Although the patents have expired, the petitioner corporation has been kept alive for the purpose of prosecuting the present action in order to secure for its former stockholders a recovery for respondent's use of these important patents,—the claim against respondent being petitioner's sole remaining asset. (See Special Findings of Fact of the court below of November 4, 1935, Nos. VI and VII, together with the documents incorporated therein by reference; Court R. pp. 9-11.)

The present petition seeks a review of the decision of the Court of Claims only with respect to the Marconi patent No. 763,772 and the Fleming patent No. 803,684. As the Marconi reissue patent expired July 13, 1914, and as respondent's use of wireless apparatus up to that date was relatively small, no review is sought of the decision of the court below with respect to that patent.

As a result of the decision of the Court of Claims, petitioner, the owner of the four fundamental patents in the radio art (all previously sustained by courts of the United States), has been awarded less than $80,000 (plus additional compensation measured by interest) for respondent's purchase or manufacture and use, during the period covered by the claim, of upwards of $40,000,000 worth of radio

[4] See footnote 12, above.

apparatus.[15] We respectfully submit that this constitutes a substantial failure of justice for reasons set forth in our supporting brief (see p. 26, *infra*).

II.

The Questions Presented.

The questions presented are as to the validity and infringment of claims 1, 2, 3, 6, 8, 10 to 14, and 17 to 20 of the Marconi patent No. 763,772 and of claims 1 and 37 of the Fleming patent No. 803,684.

III.

Reasons Relied On for the Allowance of the Writ of Certiorari.

(1) Because the Court of Claims, in finding that the Marconi patent No. 763,772 was invalid as to claims 1, 2, 3, 6, 8, 10 to 14, and 17 to 20, and in failing to find that these claims were infringed by the apparatus described in its Special Findings of Fact XLVI, XLVIII, XLIX, and L of November 4, 1935, rendered a decision in conflict with the decisions of the Circuit Court of Appeals for the Ninth Circuit and the United States District Courts for the District of Washington and for the Eastern District of New York, on the same question and on substantially the same evidence, in *Marconi Wireless Telegraph Company of America* v. *Kilbourne & Clark Manufacturing Co.* (265 Fed. 644, affirming the decision of the Washington District Court, 239 Fed. 328), and in *Marconi Wireless*

[15] Other parts of R., p. 1957. The Interdepartmental Radio Board recommended to Congress that petitioner be awarded over $1,250,000 as compensation for respondent's use of the subject matter of the Lodge patent, the Marconi patent No. 763,772, and the Fleming patent (see brief, p. 20, *infra*).

Telegraph Company of America v. *National Electric Signalling Co.* (213 Fed. 815), respectively.[16]

(2) Because the Court of Claims, in finding that claims 1 and 37 of the Fleming patent No. 803,684 were not infringed and in failing to find that these claims were valid, rendered a decision in conflict with the decisions of the Circuit Court of Appeals for the Second Circuit and the United States District Court for the Southern District of New York, on the same question and on substantially the same evidence, in *Marconi Wireless Telegraph Company of America* v. *DeForest Radio Telephone & Telegraph Co.*[17] (243 Fed. 560, affirming the decision of the District Court, 236 Fed. 942); *Same* v. *Same* (memorandum opinion of the District Court; "Other parts" R., pp. 2104-5); and *Same* v. *Same* (261 Fed. 393, S. D., N. Y.).

(3) Because the Court of Claims, in limiting petitioner's compensation, for the use by respondent of upwards of $40,000,000 worth of radio apparatus during the accounting period, to less than $80,000 (plus additional compensation measured by interest), has rendered a decision which, in view of the prior recognized fundamental position of petitioner's patents in the radio art and in view of the proposed award to petitioner by the Interdepartmental Radio Board of upwards of $1,250,000, has resulted in a failure of justice as between the United States and one of its citizens.

[16] *The National Electric Signalling Co.* decision was followed by the District Court for the Southern District of New York, on a contested preliminary injunction motion, in *Marconi Wireless Telegraph Company of America* v. *DeForest, etc., Co.*, 225 Fed. 65; this decision was affirmed by the Circuit Court of Appeals for the Second Circuit, 225 Fed. 373. (See also Plaintiff's Exhibit 345, "other parts" R., pp. 2473-7; offered "Other parts" R., p. 2094).

[17] This decision was followed by the District Court for the District of Delaware, on a contested motion for a preliminary injunction, in *Marconi Wireless Telegraph Company of America* v. *Radio Audion Co.*, 278 Fed. 628.

WHEREFORE, your petitioner respectfully prays that a Writ of Certiorari be issued out of and under the seal of this Honorable Court, directed to the Court of Claims of the United States, commanding that court to certify and send to this Court on a day to be designated, a full and complete transcript of the record and all proceedings in this cause, in so far as the same are material to the errors herein assigned, to the end that this cause may be reviewed and determined by this Court; that the judgment of the Court of Claims of the United States be reversed in so far as errors therein have been assigned by your petitioner; and that petitioner be granted such other and further relief as may seem proper.

Dated, August 31, 1942.

ABEL E. BLACKMAR, JR.,
RICHARD A. FORD,
Counsel for Petitioner.

BRIEF IN SUPPORT OF PETITION FOR WRIT OF CERTIORARI.

Opinions of the Court Below.

The 1935 opinion of the Court of Claims of the United States on the issues of validity and infringement of the patents in suit is reported at 81 Ct. Cls. 741.

The 1942 opinion of the said court on the accounting proceeding is not yet reported, but will be found in the printed record at page 157.

Jurisdiction.

1. The final judgment of the Court of Claims, now sought to be reviewed, was rendered April 6, 1942 (Court R., p. 182).

2. By an order of the Chief Justice of this Court, dated May 21, 1942, petitioner's time to file its petition for writ of certiorari was extended to September 4, 1942.

3. The judgment was rendered in an action to recover compensation for the use or manufacture by or for the respondent, the United States, of apparatus embodying the subject matter of four letters patent of the United States; the action was brought under the Act of June 25, 1910, as amended July 1, 1918 (U. S. Code, Title 35, Section 68).

4. The jurisdiction of this Court is invoked under Sections 3 and 8 of the Act of February 13, 1925, as amended by the Act of May 22, 1939 (U. S. Code, Title 28, Sections 288 and 350).

5. Some of the cases believed to sustain the jurisdiction are:

Wilson & Co. v. *United States*, 311 U. S. 104;
United States v. *Pelzer*, 312 U. S. 399;
American Chicle Co. v. *United States*, — U. S. —, 86 L. Ed. 1106;
Standard Refrigerator Co. v. *Winters*, 280 U. S. 30;
Toledo Pressed Steel Co. v. *Standard Parts*, 307 U. S. 350;
Honolulu Oil Co. v. *Halliburton*, 306 U. S. 550.

Statement of the Case.

The facts, so far as this application is concerned, are stated in the petition. We wish, however, to add the following:

Both Senatore Guglielmo Marconi and Sir Ambrose Fleming, patentees of the two patents involved in this application, were widely recognized in the radio art as having made contributions of great value to the development thereof. Their patents which were involved before the Court of Claims in the present suit cover these contributions.

The two Marconi patents covered the fundamental features which made it possible for him to be the first to transmit intelligible messages across the Atlantic Ocean and which resulted in his becoming known as the "father of wireless". His position in the art of wireless telegraphy was recognized by Congress, when, on April 13, 1938,[1] it authorized and directed the Secretary of the Interior to grant permission to the Marconi Memorial Foundation, Inc., for the erection on public grounds of the United States in the District of Columbia, of a memorial "to the late Guglielmo Marconi, inventor of an apparatus for

[1] This was after the Court of Claims had held the Marconi reissue patent not infringed and all the broad claims of the second Marconi patent invalid.

wireless telegraphy", by the American people (Public Resolution No. 86, 75th Congress).[19]

Fleming likewise initiated, by the disclosure of the invention of his patent here in suit, a tremendous advance in the wireless art. His two-element tube or "valve" was the foundation upon which DeForest built his three-element tube or "audion" which opened up a multitude of new and unsuspected possibilities and which, in various improved forms, is in practically universal use to-day.

These facts have been judicially recognized not only in this country, but, as to the subject matter of Marconi patent No. 763,772, in England and France (see the cases referred to at page 5 of the Petition).

The fundamental character of petitioner's patents here in suit was also recognized by respondent's Interdepartmental Radio Board (the functions of which are described at pages 19-20, *ante*). The representative, on that Board, of the Department of Justice, said, before a Congressional committee, that "Those four patents are all fundamental."[20]

In considering these patents, it should be borne in mind that, as they expired considerably more than six years ago, no further claim for infringement of either of them can hereafter be made by petitioner or its assignee, either against respondent or anyone else.

Specification of Errors.

The errors which petitioner will urge, if the writ of certiorari is granted, are that the Court of Claims of the United States erred:

1. In holding that claims 1, 2, 3, 6, 8, 10 to 14, and 17 to 20 of Marconi patent No. 763,772 were invalid;

[19] A copy of the Resolution is appended hereto at page 37, *ante*, as Appendix B.

[20] Pltf's Ex. 122, [illegible] R., Vol. III, p. 1072.

2. In holding that the subject matter of said claims lacked invention;

3. In holding that the subject matter of said claims, or certain of them, was anticipated in the prior art;

4. In failing to hold that said claims of Marconi patent No. 763,772 involved invention, that they covered new and useful subject matter, and that Marconi was the first inventor of the subject matter thereof;

5. In failing to hold that said claims were valid;

6. In failing to make the ultimate finding of fact that said claims of Marconi patent No. 763,772 were infringed by the apparatus described in the Special Findings of Fact of the Court of Claims, Nos. XLVI, XLVIII, XLIX, and L, of November 4, 1935 (81 C. Cls. 705-710);

7. In failing to enter a judgment awarding to petitioner compensation for the manufacture and use by and for the respondent of apparatus utilizing the subject matter of claims 1, 2, 3, 6, 8, 10 to 14, and 17 to 20 of Marconi patent No. 763,772;

8. In failing to hold that claims 1 and 37 of Fleming patent No. 803,684 involved invention, that they covered new and useful subject matter, and that Fleming was the first inventor of the subject matter thereof;

9. In failing to hold that said claims of the Fleming patent were valid;

10. In holding that said claims of Fleming patent No. 803,684 were not infringed by the apparatus described in the Special Findings of Fact of the Court of Claims, Nos. LXXV, LXXVI, LXXVIII, and LXXIX, of November 4, 1935 (81 C. Cls. 735-740);

11. In failing to hold that said claims of the Fleming patent were infringed by the apparatus described in said find-

ings Nos. LXXV, LXXVI, and LXXIX, and that claim 1 of said patent was infringed by the apparatus described in said finding No. LXXVIII;

12. In failing to enter a judgment awarding to petitioner compensation for the manufacture and use by and for the respondent of apparatus utilizing the subject matter of claims 1 and 37 of Fleming patent No. 803,684.

Summary of Argument.

The various points or propositions which are set forth under the following captions summarize the argument.

ARGUMENT.

Point I.

The Court of Claims, in holding that claims 1, 2, 3, 6, 8, to 10, 14, and 17 to 20 of Marconi patent No. 763,772 were invalid, has rendered a decision in conflict with the decisions of the Circuit Court of Appeals for the Ninth Circuit and the United States District Courts for the District of Washington and for the Eastern District of New York, on the same question and on substantially the same evidence, in Marconi Wireless Telegraph Company of America v. Kilbourne & Clark Manufacturing Co. (265 Fed. 644, affirming the decision of the Washington District Court, 239 Fed. 428), and in Marconi Wireless Telegraph Company of America v. National Electric Signalling Co. (213 Fed. 815), respectively.

Prior to the decision of the Court of Claims, the Marconi patent No. 763,772 and the corresponding British and French patents had been sustained as valid by all courts to which that question had been presented.

The first decision, in point of time, was that of Mr. Justice Parker of the High Court of Justice, Chancery Di-

vision. Its judgment was delivered February 21, 1911.[21] Justice Parker held that Marconi's British patent No. 7,777 of 1900 (plaintiff's exhibit 34, included in exhibits certified as incorporated by reference in the court's findings; offered "Other parts" R. p. 202), corresponding to his patent here in suit No. 763,772, was valid and infringed, the invention covered thereby "producing an entirely new and useful result" ("Other parts" R. Vol. III, p. 1631).

In December, 1912, the Civil Tribunal of the Seine held that Marconi's corresponding French patent (No. 305,060; plaintiff's exhibit 142, "Other parts" R. Vol. IV, p. 2009; offered "Other parts" R. p. 532) was valid and infringed.[22] That court called the invention "a wonderful conquest" and said that "the Marconi patent stands out as an unassailable monument until new discoveries are made" ("Other parts" R. Vol. III, pp. 1663, 1690; see also "Other parts" R. Vol. III, pp. 1705-6).

The first decision in this country on Marconi patent No. 763,772, here in suit, was that of Judge Veeder in the *National Electric Signalling Co.* suit above referred to (213 Fed. 815). In that case, decided in 1914, the patent was held valid and infringed, Judge Veeder stating (213 Fed. 848) that Marconi had overcome the difficulties existent in prior art arrangements, and that:

> "In combination with the increased available energy in the transmitter, the distance over which messages could be sent was enormously increased. With this apparatus Marconi communicated across the Atlantic in 1901, and the claims in issue constitute the essential

[21] The judgment in this case, *Marconi* v. *British Radio Tel. Co.*, is reported in (1911) 27 T. L. R. 274, 28 R. P. C. 181; a copy is in evidence as plaintiff's exhibit 7 ("Other parts" R., Vol. III, pp. 1600-1640; offered "Other parts" R., p. 186).

[22] A translation of the judgment in this case, *Societe Marconi* v. *Societe generale, etc.*, is in evidence as plaintiff's exhibit 36, "Other parts" R., Vol. III, pp. 1648-1708; offered "Other parts" R., p. 202.

features of apparatus which has since made possible communication over a distance of 6,000 miles. It is used in more than 1,000 installations by Marconi, and is admittedly an essential feature of the wireless art as at present known and practiced."

Judge Veeder also referred to the subject matter of this Marconi patent as a "conspicuous advance in wireless telegraphy". (213 Fed. 858.)

Judge Veeder's decision was followed, on motion for preliminary injunction, by the District Court for the Southern District of New York in *Marconi Wireless Telegraph Co. of America* v. *De Forest, etc., Co.*, 225 Fed. 65. This decision was affirmed by the Circuit Court of Appeals for the Second Circuit (225 Fed. 373).

In July, 1914, the High Court of Justice, Chancery Division (Mr. Justice Eve), again held that Marconi's British patent No. 7,777 of 1900 was valid and infringed.[3]

In December, 1916, Marconi's American patent was again held valid, this time by the District Court for the District of Washington in the *Kilbourne & Clark Mfg. Co.* case above referred to (239 Fed. 328). Although the court there held that the patent had not been infringed, yet the decree (dated July 16, 1917) specifically held that Marconi patent No. 763,772 is "good and valid in law as to claims 1, 2, 3, 6, 8, 10, 11, 12, 13, 14, 16, 17, 18, 19, and 20" and that "Marconi was the first, true, original and sole inventor of the inventions described in said Letters Patent and claimed in the said claims" (plaintiff's Exhibit 364, ~~"Other parts"~~ Exhibit R., Vol. IV, pp. 2504-2; offered "Other parts" R., p. 2103). This District Court stated that what Marconi did "was a feat accomplishment" and that the ideas involved in the

[3] The judgment in this case, *Marconi* v. *Helsby Wireless Telegraph Co.*, is reported in (1914) 30 T. L. R. 633, 31 R. P. C. 399; a copy is in evidence as plaintiff's exhibit 35 (~~"Other parts"~~ Exhibit R., Vol. III, pp. 1642-7, offered "Other parts" R., p. 202).

patent "have proven of great value to the world." (239 Fed. 335, 342.)

The defendant, in the *Kilbourne & Clark* case, took a cross appeal from the adjudication of validity of the Marconi patent; on this appeal, the Circuit Court of Appeals for the Ninth Circuit considered the question of validity (see 265 Fed. 644, 661) and affirmed the degree of the District Court upholding the patent. In this respect, the Court of Claims was in error in stating (81 C. Cls. 762) that the validity of the Marconi patent was not passed upon in the *Kilbourne & Clark* case.[24]

In the face of this formidable array of decisions holding the Marconi patent valid, the Court of Claims, although stating in its 1937 Special Finding XLIV herein (81 C. Cls. 705) that

> "The invention of patent #763772 went into wide use in the United States and elsewhere. Apparatus embodying the invention of #763772 was employed in the first transatlantic radio signalling",

nevertheless held the patent invalid.

All of the prior art relied upon by the respondent in the present case with respect to this Marconi patent was admittedly involved in one or another of the prior American suits based on that patent (respondent's expert Loftin, "Other parts" R., p. 1068). For example, Marconi's prior patent No. 627,650 was discussed by Judge Veeder in the *National Electric Signalling* case, 213 Fed. 815, 859-860; the corresponding British patent was also discussed by Mr. Justice Parker ("Other Parts" R., Vol. III, p. 1609). The Tesla patent No. 645,576 was also discussed by Judge Veeder (213 Fed. 855-7) as well as by the French court ("Other Parts"

[24] Even though the Marconi patent was held not infringed in the *Kilbourne & Clark* case, the adjudication of validity "stands as an adjudication of one of the issues litigated." *Electrical Fittings Corp.* v. *The Thomas & Betts Co.*, 307 U. S. 241.

R., Vol. III, pp. 1685-1690). And the alleged 1899 correspondence between Stone and Baker was in evidence in the *Kilbourne & Clark* case and quoted, in part, in the opinion of the District Court (239 Fed. 339).

The prior American decisions were rendered after strenuously contested trials in which some or all of the testimony was taken in open court. In the Court of Claims, on the other hand, all of the testimony on the issues of validity and infringement was taken before an Examiner, usually a Notary Public; even the Commissioner who made the report on validity and infringement had heard none of the testimony.

Of course, the accomplishment of a patentee is measured by the advance made by him over the sum of human knowledge available at the time he made his invention. It is therefore important to appreciate that the decisions in all of the prior cases were rendered at a much earlier stage of the radio art, *i. e.*, at a time when the point of view of the witnesses, especially of the experts, more nearly reflected the point of view existent at the time the invention was made. The decision of the Court of Claims was rendered some thirty-five years after Marconi made the invention covered by his patent No. 763,772, after the phenomenal development of the art that started about 1916 as a result of the incentive of the World War of 1914-1918, and after years of advanced and intensive study and research which naturally made the original advances in the art seem, by comparison, simple and obvious. In other words, by 1935, when the first decision below was rendered, it had become extremely difficult, if not impossible, to recapture the point of view of 1900, whereas, in 1911-1916, when the prior decisions were rendered, comparatively little advance had been made in the art and the work of Marconi and other early inventors could be more easily seen in its true perspective. That which was made to the court below to appear, in 1935, to

have been obvious in 1900, did not appear to at least four courts, in 1911-1916, to have been obvious. Petitioner submits that this fact alone should lead this Court to scrutinize the decision of the Court of Claims in a review of this case.

In addition to the prior decisions mentioned above, consideration should also be given to the following facts:

In 1919, after the termination of the first World War, the Attorney General, the Secretary of the Navy, and the Secretary of War organized the Interdepartmental Radio Board, a group of representatives of these three departments. The function of the Board was to consider the claims of owners of various patents for inventions in the radio field for compensation for the use of the inventions by the United States during the war period, and to recommend the amount of compensation, if any, to which the claimants were entitled. ("Other parts" R., pp. 1099 *et seq.*)

The Board included a patent attorney of long experience in litigation involving radio patents, and a Naval officer (Lieutenant Commander Loftin, Chairman of the Board) who subsequently acted as the chief technical expert for respondent in the present case. The Board undertook "a very careful consideration of the whole situation"; it familiarized itself not only with the many patents on which claims were based but with the great mass of applicable prior patents and publications, possible prior uses where known, prior litigation involving the patents, and the structure and operation of such of respondent's apparatus as was asserted to infringe. Informal hearings were held. The Board determined whether and to what extent, in its opinion, the patents were valid and infringed,—seeking to arrive at the conclusion that would be arrived at by the Courts of Claims. ("Other parts" R., pp. 1099 *et seq.*) The work of the Board extended over a period of nearly two years and a half ("Other parts" R., p. 1104).

In 1921, the Board recommended to the heads of the three Departments that petitioner be awarded compensation in the sum of over $1,250,000 for respondent's use of the Lodge patent, the Marconi patent No. 763,772, and the Fleming patent. This recommendation was accepted by the heads of the Departments, as well as by the petitioner.

The recommendations were thereafter presented to the Committee on Military Affairs of the House of Representatives. At the Committee hearings, the Board was represented primarily by Commander Loftin who urged that Congress accept the recommendations and appropriate the funds to pay the various claimants (Plaintiff's Exhibit 122, "Other parts" R., pp. 1934 *et seq.*; offered "Other parts" R., p. 1098). The Committee on Military Affairs reported the proposed bill favorably to the House of Representatives (Plaintiff's Exhibit 363, "Other parts" R., Vol. IV, pp. 2496 *et seq.*; offered "Other parts" R., p. 2103), but Congress failed to pass the necessary legislation.

Thus there are arrayed against the 1935 decision of the court below to the effect that the above-mentioned claims of Marconi patent No. 763,772 were invalid the following decisions:

1. The 1914 decision of Judge Veeder in the Eastern District of New York (and the decisions of the southern New York District Court and the Second Circuit Court of Appeals which followed Judge Veeder's decision);

2. The 1920 decision of the Circuit Court of Appeals for the Ninth Circuit affirming the 1916 decision of the District Court for the District of Washington;

3. Two decisions, rendered in 1911 and 1914, of the High Court of Justice, Chancery Division, in England;

4. The 1912 decision of the Civil Tribunal of the Seine, in France; and

5. The recommendation, in 1921, of respondent's Interdepartmental Radio Board.

Petitioner respectfully submits that, under the circumstances above set forth, this Court should grant petitioner's writ of certiorari and review the decision of the Court of Claims as to the validity of claims 1, 2, 3, 6, 8, 10 to 14, and 17 to 20 of Marconi patent No. 763,772.

On the issue of infringement of said claims of this second Marconi patent in suit, it is clear from the 1935 Special Findings of Fact of the Court of Claims, Nos. XLVI, XLVIII, XLIX, and L, and from the opinion of that Court that that court considered that, if the claims were valid, they were infringed by respondent's apparatus described in those Findings. Therefore, no review of such Findings is requested by petitioner; the only thing that is sought on this issue is the ultimate Finding that said claims of Marconi patent No. 763,772 were infringed by such apparatus.

Point II.

The Court of Claims, in holding that claims 1 and 37 of Fleming patent No. 803,684 were not infringed, and in failing to hold that these claims were valid, has rendered a decision in conflict with the decision, rendered on the same questions and on substantially the same evidence, of the Circuit Court of Appeals for the Second Circuit, in Marconi Wireless Telegraph Company of America v. De Forest Radio Telephone & Telegraph Co. (243 Fed. 560, affirming 236 Fed. 942), *and the two subsequent decisions of the United States District Court for the Southern District of New York in the same case (memorandum opinion of July 11, 1917, not reported,[25] and 261 Fed. 393).*

[25] This memorandum opinion appears at "Other parts" R., Vol. IV, pp. 2104-5.

The trial of the case against DeForest Radio Telephone & Telegraph Co. was a strenuously contested trial, substantially all of the evidence having been taken in open court. The questions involved were identical with those in the present case, namely, whether claims 1 and 37 of the Fleming patent were valid and whether they were infringed by the use of three element vacuum tubes (then usually referred to as "audions") in wireless or radio detection (the use described in the 1935 Special Findings of Fact of the Court of Claims herein, Nos. LXXV and LXXIX; 81 C. Cls. 735, 749). The District Court (the late Judge Mayer) held that the patent was valid and infringed; the decision was affirmed on appeal, Judge Hough writing the opinion.[26]

On a motion to extend the injunction in the *DeForest* case to cover the use of three-element tubes in amplifiers and in generators of oscillations ("oscillators" or "Oscillions"), the District Court held, in a memorandum opinion (~~Other pates~~ R., pp. 2104-5), that amplifiers, being part of a detector, were within the prior decree but that, as to oscillators, further evidence should be presented.

Accordingly, there was a further trial in open court after which the District Court held that the use of three-element tubes in generators of oscillations infringed claim 1 of the Fleming patent.[27]

The Fleming patent was also before the Interdepartmental Radio Board, which recommended that petitioner receive compensation for respondent's use of three-electrode tubes in detectors, amplifiers, and oscillators.

In direct conflict with these decisions, the Court of Claims held, on evidence taken before an Examiner, that none of

[26] This decision was followed, on a contested motion for preliminary injunction, by the District Court for the District of Delaware, in *Marconi Wireless Telegraph Co. of America* v. *Radio Audion Co.*, 278 Fed. 628.

[27] No appeals were taken by the defendant from the decisions that the patent was infringed by amplifiers and oscillators.

the apparatus used by respondent infringed either claim 1 or claim 37 of the Fleming patent.

As in the case of the Marconi patent, all of the prior art here relied upon by respondent with respect to the Fleming patent was admittedly involved in the prior (DeForest) litigation (Loftin, "Other parts" R., p. 1068).

As to the decisions of the courts in the *DeForest* case, the Court of Claims said, first, "that both sides represented to the Court and agreed that the inherent qualities of the two-electrode tube and the three-electrode tube are the same." (81 C. Cls. 781); and, second, that those decisions were "quite incorrect" (81 C. Cls. 784).

As to the former statement, the Court of Claims was, we submit, in error.[2]

Contrary to the inference that might be drawn from this statement in the opinion of the Court of Claims, the *DeForest* case was a bitterly contested one.

The plaintiff in that case (petitioner here) did, of course, take the position that the two-electrode tube or Fleming valve was inherently capable of performing the same functions as the three-electrode tube or audion—just as it has done in this case. But the defendant in the *DeForest* case,

[2] The statement in Judge Mayer's opinion (246 Fed. 963) that "both sides agree that the *DeForest* two-element and three-element bulbs operate on the same principle", and that of the Circuit Court of Appeals (243 Fed. 565) that "it is agreed that the 'two' and 'three' electrode *audions* operate on the same basic principle" apparently misled the Court of Claims. What was meant by these statements is clarified by the Court of Appeals at 244 Fed. 562, where it is pointed out that the defendant in that case "insisted that the [Fleming] valve and the Audion utilize and depend for efficacy upon wholly different operations of nature". It was only in connection with certain *DeForest* patents (subject matter of a counterclaim and held either invalid or not infringed) as to which defendant contended that the principle of operation was the same, it was the devices of these patents that the courts in the *DeForest* case referred to in speaking of "DeForest two element" bulbs and "two-electrode audions"—not the device of the Fleming patent.

(Emphasis in this brief, is ours unless otherwise stated.)

like the respondent here, took the definite position that the audion operated on entirely different principles from the Fleming valve. To support this statement of ours and to show that the court below misunderstood the position of the defendant in the *DeForest* case, we here quote from briefs of that defendant. In the main brief before the District Court, counsel for the DeForest Company said:

> "The attempt to make out infringement [of the Fleming patent] by saying that the Audion has the Fleming circuit 'split up' is too vague a generalization in view of *the different operation of the two devices resulting from the existence of two instead of one circuit.*"
>
> "* * * a patentee cannot expand his patent to cover changes which cause the device to *function in an entirely different manner.* * * *" (P. 339).
>
> "The attempt now being made to sweep within the monopoly of the Fleming patent the PN Audion with its *radically different mode of operation*, is similar", etc. (P. 341.)

In the main brief for the DeForest Company before the Circuit Court of Appeals appears (at page 62) a heading reading as follows:

> "The Audion and its Mode of Operation are *Vitally Different in all Essential Features* from the Fleming Device and Fleming's Mode of Operation."

It is then stated that

> "The audion is *radically different* from the device of the Fleming patent *in principle, in essentials of apparatus and circuit connections, in purpose, and in the uses to which it is put.*"

There follows a section of over twenty-five pages devoted to an effort to show so-called "*Contrasting Laws of Operation* of Fleming and of the Audion" (pp. 63-90). And the Circuit Court of Appeals said (243 Fed. 562) that defendant

(the DeForest Company) insisted "that the [Fleming] valve and the audion utilize and depend for efficacy upon *wholly different operations of nature.*"

In fact the DeForest Company, in its briefs in that case, made substantially every argument of non-infringement that the respondent has made herein.

We respectfully submit that the Court of Claims, in stating that the decision in the *DeForest* case "has no application to the instant case" (81 C. Cls. 781) was clearly in error.

The statement of the Court of Claims that the decision of the Court of Appeals in the prior case was "quite incorrect" merely emphasizes the conflict between the two decisions and shows that the present case falls directly within the category of cases in which this Court normally grants a writ of certiorari.

The Court of Claims made no finding herein as to the validity of the Fleming patent. In its opinion, however, it indicated (81 C. Cls. 774) that it considered the Fleming patent to be invalid because of unreasonable delay in making the disclaimer. In this respect, again, the Court of Claims was in conflict with the decisions in the *DeForest* case. The Court of Appeals held in that case (243 Fed. 565) that the disclaimer was proper and did not affect the validity of the patent.[29]

Petitioner respectfully submits that, in view of the direct conflict of decision between the Court of Claims and the Circuit Court of Appeals for the Second Circuit with respect to the Fleming patent, this Court should review the

[29] It cannot be said that this decision was reached without proper presentation of the question on behalf of the DeForest Company, for, in a Supplemental Memorandum, presented by the late Frederick P. Fish (probably the leading patent attorney of the Bar at that time), several pages were devoted to the argument that the "Fleming Patent is Void Because • • • there was Unreasonable Neglect and Delay in Filing the Disclaimer." (Pp. 1 to 11 of said supplemental Memorandum.)

judgment herein holding that petitioner is not entitled to compensation with respect to that patent.

Point III.

The Court of Claims, in limiting petitioner's compensation, for the use by respondent of upwards of $40,000,000 worth of radio apparatus during the accounting period, to less than $80,000 (plus additional compensation measured by interest), has rendered a decision which, in view of the prior recognized fundamental position of petitioner's patents in the radio art and in view of the proposed award to petitioner by the Interdepartmental Radio Board of upwards of $1,250,000, has resulted in a failure of justice as between the United States and one of its citizens.

We have set forth above the function of and procedure followed by the Interdepartmental Radio Board, the fact that it described petitioner's patents involved in this case as the fundamental patents in the radio art, and its recommendation that Congress appropriate over $1,250,000 as compensation to petitioner. Although the action of the Board was without prejudice and is therefore not binding on respondent, yet we submit that it should be considered here in view of the character and purpose of the Board. Its recommendation with respect to petitioner's claim shows what the Departments of Justice, Navy, and War considered, after over two years' study of the radio patent situation, that petitioner was entitled to receive from respondent.

We respectfully submit that the judgment of the Court of Claims, awarding to petitioner a sum only about 6½% of the sum recommended by the Interdepartmental Radio Board, should challenge the attention of this Court and that this Court should not permit the judgment to stand without a review of the findings upon which it was based.

Point IV.

The Marconi patent No. 763,772 was valid as to claims 1, 3, 5, 6, 8, 10 to 14, and 17 to 20 thereof, and the subject matter of said claims was used by respondent.

A. *Said claims of the patent were valid.*

The substance of the invention of Marconi patent No. 763,772 is very simply and briefly stated in the Petition (*supra*, pp. 3-4).

The general principles of wireless that are essential for an understanding of the invention of this patent and of what preceded it; the history of the art up to the time Marconi made the invention covered by this patent; and the nature of the invention, as well as what was accomplished thereby (both scientifically and practically), are set forth in considerable detail in the opinions of Judge Wooley and of Mr. Justice Parker, above referred to.

It does not appear to us to be necessary, at this stage of the case, to add to these statements nor to argue at length the merits of the case. Also, in petitioner's opinion, the discussion in the two above decisions and that of the French court of the prior art and of the question of presence of invention is a sufficient treatment thereof for present purposes. The only evidence bearing on the validity of the Marconi patent that can be found in the Special Findings of the court below which was not discussed in these prior decisions is the so-called "Stone defense".

Stone is alleged to have written two letters (of doubtful authenticity as to dates) to Baker prior to Marconi's application date (defendant's Exhibits F-3 and G-3; included in the exhibits that were incorporated in the court's 1935 Findings; offered "Other parts" R., p. 733); excerpts from the letters are quoted in the opinion of the District Court

in the *Kilbourne* v. *Clark* case (which held the Marconi patent to be valid)[30] and in the Findings of the court below. There was also in evidence a patent to Stone, No. 714,756 (defendant's Exhibit X-3; included in the exhibits incorporated in the court's 1935 Findings; offered "Other parts" R., p. 866) the application for which was filed prior to the Marconi application but which did not issue as a patent until after the Marconi application had been filed.

Petitioner submits that the Stone-Baker letters, even if authentic (which is doubtful) do not disclose the Marconi invention; that, even if they do, they do not, under existing law, invalidate the Marconi patent; and that the Stone patent application, as it existed at any time prior to Marconi's date, did not disclose the Marconi invention.[31]

The court below did not hold the Marconi patent invalid on the basis of the Stone-Baker letters, saying (81 C. Cls. 767 at 811) "it is not necessary that we should decide whether a private letter such as Stone wrote to his friend would constitute a disclosure which would affect the Marconi patent * * *."

Judging from the 1935 opinion of the Court of Claims, the Marconi patent was held invalid for want of invention

[30] The court below evidently overlooked this fact for it stated in its opinion (81 C. Cls. 767) that

> "It was unnecessary for him [Judge Neterer] to pass on the validity of the Marconi tuning patent and he did not do so. * * *. If any inference is to be drawn from his opinion it is that it was proper to take into consideration the Stone letters."

However, Judge Neterer signed a decree upholding the validity of the Marconi patent (see supra, p. 16).

[31] With this last point, the court below apparently was in agreement. After making certain quotations from the Stone *patent* which might be argued to describe the Marconi invention, the court said (in its 1935 Special Finding LIV, 81 C. Cls. 716):

> "The quotations from lines 16-20 of page 2 and lines 62-66 of page 6 of the Stone specification were inserted by the amendment of April 8, 1902, after the application was filed in the Patent Office."

The Marconi application was filed November 10, 1900.

and this holding was based on the same prior patents and publications that had been considered in the prior decisions. The holding was therefore not based on new evidence and was in direct conflict, not only as to result but also as to reasoning, with the prior decisions. Further discussion, on the merits, of the validity of the Marconi patent therefore does not appear necessary at this stage of the case.

B. *The above-mentioned claims of the Marconi patent were infringed.*

As to the merits of the question of infringement, it seems necessary only to quote from the opinion of the Court of Claims:

> "We think it clear that the plain open-gap apparatus would be an infringement if the patent was valid, and we are likewise of the opinion that this would be true as to the apparatus using the rotary gap * * *." (81 C. Cls. 768.)

As to quenched-gap apparatus, the opinion stated:

> "It also appears that when it was used it was necessary to follow the same method of tuning as before." (81 C. Cls. 769.)

It seems clear that the court below considered that, if the patent were valid, it was infringed.

Petitioner therefore submits that, with respect to Marconi patent No. 763,772, the merits of the case are such that, in view of the direct conflict of decision as to the validity of the patent, this Court should review the decision of the court below denying to petitioner compensation based on that patent.

Point V.

The Fleming patent No. 803,684 was valid as to claims 1 and 37 thereof and the subject matter of said claims was used by respondent.

A. The patent was infringed.

The Fleming patent constituted the first disclosure of a multiple-element vacuum tube for use at the high electrical frequencies employed in radio—frequencies normally above 15,000 cycles per second and running up into millions of cycles. The specific disclosure of the patent was the use of a two-element vacuum tube ("Fleming valve") as the rectifying element of a radio detector.

Rather than attempt to set forth here the technical details of the operation of vacuum tubes we refer this Court to its own decisions in *Radio Corporation of America* v. *Radio Engineering Laboratories*, 293 U. S. 1, 10-11 and in *DeForest Radio Co.* v. *General Electric Co.*, 283 U. S. 664, 670 *et seq.*, and, with particular reference to the Fleming patent, to the decisions of the District Court and the Circuit Court of Appeals in the *DeForest* suit on that patent (239 Fed. 942 and 243 Fed. 560).

The controlling fact on the question of infringement is that Fleming taught the art that the action of a vacuum tube containing an incandescent electrode (filament or cathode) and another, cold, electrode (plate or anode) was substantially without inertia, that such a tube would operate at or respond to the extremely high frequencies used in radio, and, specifically, that suitable electrical circuits and apparatus, utilizing such a vacuum tube, operated to detect the presence of radio signals.

Dr. Lee DeForest, who had been carrying on abortive experiments with various gaseous devices for use in radio, learned of Fleming's invention and, shortly afterwards,

added a third element inside of the vacuum tube which, in a later form, was located between the filament and the plate of the Fleming valve and became known as the "grid" or "control electrode".

This was an invention of great importance, as has been universally recognized, but it was a direct outgrowth of and was built on the Fleming invention. As this Court expressed it in *Radio Corporation* v. *Radio Engineering Laboratories*, 293 U. S. 1, at p. 11:

> "DeForest's 'audion' changed the Fleming tube by interposing a special wire known as the 'grid' between the filament and the plate, thereby increasing its capacity as a detector of waves of radio or inaudible frequency and serving better to transform them into waves of audible frequency."

That the DeForest tube was a direct out growth of and built on the Fleming invention was specifically held by both courts in the *DeForest* case (236 Fed. at page 955 and 243 Fed. at page 566). The Circuit Court of Appeals said:

> "He [DeForest] began with the heated gas theory; he ended with the three-electrode audion, employing the commercial vacuum, and before he produced that success he learned of Fleming's invention and the latter's address before the Royal Society."

The Court of Claims, in the present case, disregarded this fact and, we submit, considered the question of infringement on narrow, technical grounds.

For the purposes of the present petition, we submit that, without further argument, it is clear that a decision of non-infringement under the circumstances stated above and under Point II, especially in view of the prior contrary decision of the Circuit Court of Appeals for the Second Circuit, is one which calls for review by this Court.

It seems unnecessary to consider here the further findings

of the court below (also contrary to the decisions of the Southern New York District Court) that the Fleming patent was not infringed by respondent's use of amplifiers and generators of oscillations utilizing three-element tubes or audions, since the direct conflict with the decision of the Circuit Court of Appeals on the question of infringement by detectors should, in our opinion, be sufficient to induce this Court to review the case.

B. *The Fleming patent was valid.*

On the question of validity, the Court of Claims, in its opinion, stated that it considered the patent invalid because of unreasonable neglect and delay in filing the disclaimer, citing the decision of this Court in *Easton* v. *Simon Asher & Co.*, 282 U. S. 445, 452. This question, as we have shown above, was specifically before the New York courts in the *De Forest* case, but was overruled by both courts.

The disclaimer limited the subject matter of the patent to use of the Fleming valve with high or radio frequencies; it therefore did no more than limit the patent to the invention which was described therein specifically and in considerable detail. It in no wise affected claim 37 of the patent (one of the claims here in suit).

Even if the patent, as originally issued, may be said, in claim 1 or elsewhere, to have attempted to cover the use of the Fleming valve as a rectifier of low frequencies, it did not seek to cover "more than that of which he [the patentee] was the original or first inventor or discoverer" (the situation to which the disclaimer provisions of the statute apply). For, so far as appears from the record herein, Fleming was the original and first inventor or discoverer of the fact that the two-element vacuum tube would rectify low frequency, alternating currents (respondent's witness Miller, "Other parts" R., p. [illegible], 672).

Under such circumstances, the disclaimer provisions of the patent statutes and the decision of this Court in the *Enston* case have no application.[32] These provisions, embodied in Revised Statutes sections 4917 and 4922 (U. S. Code, Title 35, sections 65 and 71), are set forth in Appendix C (*infra*, pp. 38-39). By their terms they are applicable only when the patentee "has claimed *more* than that of which *he* was the original or first inventor or discoverer" or when he has "claimed to be the original and first inventor or discoverer of any material or substantial part of the thing patented, of which *he* was *not* the original and first inventor and discoverer".

Respondent has not shown that Fleming was not the first inventor or discoverer of low-frequency rectification—the disclaimed matter. Therefore, even if Fleming disclosed such low-frequency rectification a considerable time before he filed his application for the patent in suit, and even if the patent, as issued, purported to cover such use of the Fleming valve, nevertheless the patent did not claim more than that of which Fleming was the original and first inventor or discoverer. The disclaimer provisions of the statute, therefore, by their specific terms, do not apply to the Fleming patent.

We of course do not assert that, if Fleming published a description of the use of his tube as a rectifier of low frequency currents more than two years before his application was filed, he had the right validly to claim such use in the patent. What we do assert is that the Court of Claims was clearly in error in attempting to apply the disclaimer provisions and in asserting that the patent was void for unreasonable neglect and delay in filing a disclaimer.

[32] In the case of the Enston patent, the invalid claim was too broad and included "More than that of which he, the patentee, was the original or first inventor or discoverer." *Enston* v. *Rock-Sampliner Co.*, 13 Fed. (2d) 132, 133.

Even if the disclaimer sections of the statute were applicable to the circumstances above set forth, and even if, in so far as the patentee himself was concerned, it might be thought that there was unreasonable neglect and delay, we nevertheless submit that those sections do not invalidate the patent in so far as *petitioner* is concerned.

We note, first, that Revised Statutes section 4917 states that the patent "*shall be valid* for all that part which is truly and justly" the patentee's, and that the "patentee, his heirs *or assigns*, whether of the whole or any sectional interest therein, *may* * * * make disclaimer", etc. The statute also provides that the disclaimer is applicable only to the interest possessed by the one filing it (and those claiming under him).

In Revised Statutes section 4922, we find the provision that a suit at law or in equity may be maintained by the "patentee, his executors, administrators, and *assigns*" for infringement of any part of the patent "which was *bona fide* his own, * * * notwithstanding the specifications may embrace more than that of which the patentee was the first inventor or discoverer." The section then provides, as penalty for failure to file a disclaimer before commencement of suit, that "plaintiff" (i. e., the patentee, his executors, administrators, or assigns) shall not recover costs. The last sentence of the section reads:

> "But *no patentee* shall be entitled to the benefits of this section if he has unreasonably neglected or delayed to enter a disclaimer."

This is the only portion of the statute which requires that the disclaimer be filed promptly. In the absence of this sentence, failure to file a disclaimer would only affect the recovery of costs and, by the very terms of the statute, the patent would be valid as to all parts thereof of which the patentee was the first inventor or discoverer.

Throughout these two sections, Congress carefully distinguished between the patentee and those claiming under him (such as his assignees). The provision as to unreasonable neglect and delay applies, by its terms, only to the patentee and not to his assigns. Thus Congress saw fit to deprive a dilatory patentee (who had made oath to certain facts) of the benefits of this remedial statute but did not see fit to deprive his assignee of such benefits.[53] If it had been the intention of Congress, to make no distinction here between the patentee and his assignee, there would have been no difficulty in making this sentence read that no one maintaining such a suit at law or in equity should be entitled to the benefits of the section if there had been unreasonable neglect and delay in entering a disclaimer. Such, however, is not the way that the statute reads.

Petitioner therefore submits, as to the disclaimer, first, that Revised Statutes sections 4917 and 4922 do not apply where, as here, the patentee was himself the first inventor or discoverer of the disclaimed subject matter; and second, that the unreasonable neglect and delay provision of Revised Statutes section 4922 does not apply to the assignee of a patent.

We also submit that a proper construction of the patent, as originally issued and without the disclaimer, would construe claim 1, if necessary to sustain the validity thereof, as limited to the use of the apparatus thereof in connection with high-frequency currents, as described in the specification; that therefore, the disclaimer was unnecessary; and that the disclaimer, in any event, did no more than clarify the scope of the patent and should not be held to have invalidated it, or to have deprived petitioner of the right to recover from respondent for its unauthorized use of the subject matter thereof.

[53] Note that the far less drastic provision (that relating to costs) does, by the terms of the statute, apply both to patentee *and* assignee.

The Court of Claims, in its opinion, did not specifically pass on the other grounds of invalidity urged by respondent. The opinion, to us, indicates that the court below considered that, except for the disclaimer, the patent was valid. In view of the careful consideration of these other questions by the two New York courts, the lower of which had seen and heard the witnesses, we do not think that further discussion of the question of validity is necessary at this stage of the present case.

Petitioner therefore submits that, with respect to the Fleming patent, the merits of the case are such that, in view of the direct conflict between the decisions of the Court of Claims and of the Circuit Court of Appeals for the Second Circuit, this Court should review the decision of the Court below denying to petitioner compensation based on the Fleming patent.

Conclusion.

Wherefore, Petitioner respectfully prays that the petition for writ of certiorari be granted, the cause reviewed, and the judgment of the Court of Claims reversed in so far as error therein has been assigned by Petitioner.

Respectfully submitted,

Abel E. Blackmar, Jr.,
Richard A. Ford,
Counsel for Petitioner.

APPENDIX A.

Act of June 25, 1910, as amended July 1, 1918 (U. S. Code, Title 35, section 68): Whenever an invention described in and covered by a patent of the United States shall hereafter be used or manufactured by or for the United States without license of the owner thereof or lawful right to use or manufacture the same, such owner's remedy shall be by suit against the United States in the Court of Claims for the recovery of his reasonable and entire compensation for such use and manufacture: *Provided, however*, That said Court of Claims shall not entertain a suit or award compensation under the provisions of this act where the claim for compensation is based on the use or manufacture by or for the United States of any article heretofore owned, leased, used by, or in the possession of the United States: *Provided further*, That in any such suit the United States may avail itself of any and all defenses, general or special, that might be pleaded by a defendant in an action for infringement, as set forth in title sixty of the Revised Statutes, or otherwise: *And provided further*, That the benefits of this act shall not inure to any patentee who, when he makes such claim, is in the employment or service of the Government of the United States, or the assignee of any such patentee; nor shall this act apply to any device discovered or invented by such employee during the time of his employment or service.

APPENDIX B.

Resolved by the Senate and House of Representatives of the United States of America in Congress assembled, That the Secretary of the Interior be, and he is hereby, authorized and directed to grant permission to The Marconi Memorial Foundation, Inc., for the erection on public grounds of the United States in the District of Columbia, other than those of the Capitol, the Library of Congress, and the White House, of a memorial of simple and artistic form to the late Guglielmo Marconi, inventor of an apparatus for wireless telegraphy, by the American people: *Provided*, That the site chosen and the design of the

memorial shall have the approval of the National Commission of Fine Arts and that the United States shall be put to no expense in or by the erection of the said memorial: *Provided further*, That unless funds, which in the estimation of the Secretary of the Interior are sufficient to insure the completion of the memorial, are certified available, and the erection of this memorial begun within five years from and after the passage of this legislation, the authorization her by granted is revoked.

APPENDIX C.

Revised Statutes section 4917 (U. S. Code, Title 35, section 65): Whenever, through inadvertence, accident, or mistake, and without any fraudulent or deceptive intention, a patentee has claimed more than that of which he was the original or first inventor or discoverer, his patent shall be valid for all that part which is truly and justly his own, provided the same is a material or substantial part of the thing patented; and any such patentee, his heirs or assigns, whether of the whole or any sectional interest therein, may, on payment of the fee required by law, make disclaimer of such parts of the thing patented as he shall not choose to claim or to hold by virtue of the patent or assignment, stating therein the extent of his interest in such patent. Such disclaimer shall be in writing, attested by one or more witnesses, and recorded in the Patent Office; and it shall thereafter be considered as part of the original specification to the extent of the interest possessed by the claimant and by those claiming under him after the record thereof. But no such disclaimer shall affect any action pending at the time of its being filed, except so far as may relate to the question of unreasonable neglect or delay in filing it.

Revised Statutes section 4922 (U. S. Code, Title 35, section 71): Whenever, through inadvertence, accident, or mistake, and without any willful default, or intent to defraud or mislead the public, a patentee has, in his specification, claimed to be the original and first inventor or discoverer of any material or substantial part of the thing patented, of which he was not the original and first inventor or discoverer, every such patentee, his executors, adminis-

trators, and assigns, whether of the whole or any sectional interest in the patent, may maintain a suit at law or in equity, for the infringement of any part thereof, which was bona fide his own, if it is a material and substantial part of the thing patented, and definitely distinguishable from the parts claimed without right, notwithstanding the specifications may embrace more than that of which the patentee was the first inventor or discoverer. But in every such case in which a judgment or decree shall be rendered for the plaintiff, no costs shall be recovered unless the proper disclaimer has been entered at the Patent Office before the commencement of the suit. But no patentee shall be entitled to the benefits of this section if he has unreasonably neglected or delayed to enter a disclaimer.

THE UNITED STATES,

Respondent.

REPLY BRIEF FOR PETITIONER IN SUPPORT OF PETITION FOR WRIT OF CERTIORARI

Most of the arguments set forth in respondent's brief were anticipated in the petition and supporting brief and are there, we believe, fully answered. We will therefore here confine ourselves to two of the subjects discussed in respondent's brief.

(1) There is adequate basis for review under the Act of February 13, 1925, as amended May 22, 1939:

Section 3 of the Act of February 13, 1925 (U. S. Code, Title 28, section 288), *prior to the amendment of 1939*, provided that none of the evidence in a case before the Court of Claims should be included in the transcript of record on petition to this Court for a writ of certiorari. The record

We submit that the 1939 amendment made the decisions of this Court in cases like *Thomson Co.* v. *Ford Motor Co.*, 265 U. S. 445, 447, and *Sanitary Co.* v. *Winters*, 280 U. S. 30, 36, applicable to cases brought here from the Court of Claims. These cases pointed out, first, that the general rule, on review of decisions of circuit courts of appeals (as on review of decisions of the Court of Claims), is that concurrent findings of the lower courts on questions of fact will be accepted by this Court unless clear error is shown; it was then said, in the *Thomson* case (265 U. S., at p. 447):

> "We think, however, that this rule should not be strictly applied in cases brought here because of a conflict of decision in the different circuit courts of appeal, and have therefore given consideration to the question as to which of the decisions upon this question of fact, in the light of the prior art, is based upon the sounder reasoning."

Where two courts have reached diametrically opposed conclusions on substantially the same evidence, the question as to which conclusion is correct becomes, we submit, in effect a question of law.

(2) The decision of the Court of Claims herein that claims 1, 2, 3, 6, 8, 10-14, and 17-20 of Marconi patent No. 763,772 were invalid and that claims 1 and 37 of the Fleming patent had not been infringed was in direct conflict with prior decisions of other courts, including circuit courts of appeals:

(a) As to the decision in *Marconi Wireless Telegraph Company of America* v. *Kilbourne & Clark Mfg. Co.*, 239 Fed. 328, affirmed 265 Fed. 644 (Circuit Court of Appeals for the Ninth Circuit), respondent asserts (brief, p. 11) that the so-called "Stone defense" was presented solely to sustain the defense of "noninfringement of the invention as

limited by the prior art,' "—seeking thus to explain away the specific holding in the decree in that case that the Marconi patent No. 763,772 was valid. Respondent's assertion is not in accord with the facts.

The defendant in the *Kilbourne & Clark* case devoted over 90 pages of its brief before the district court to an attempt to show "prior invention" and "prior knowledge" of the subject matter of the Marconi patent by Stone; the conclusion stated in the brief was that "In all essentials Stone is an exact anticipation of Marconi." (Brief for Defendant, p. 212.)

Similarly, over 50 pages of defendant's appeal brief, in the *Kilbourne & Clark* case, was devoted to the alleged anticipatory character of the "Stone defense", defendant's conclusion reading—

> "The Stone anticipation ought to be conclusively adjudicated now by effectuating the favorable Stone dicta of the Court below and declaring the Marconi patent invalidated by Stone; because while defendants commercial apparatus is so clearly non infringing, yet the validity issue may become important in connection with apparatus made for the government on its specifications." (Brief for Kilbourne & Clark Mfg. Co., p. 435.)

The so called "Stone defense" was therefore litigated in the *Kilbourne & Clark* case on the issue of validity. As the Marconi patent was there held valid, the decision of the Court of Claims herein is in direct conflict therewith.

Likewise, the Tesla patent, No. 645,576, was considered at length in defendant's briefs in the *Kilbourne & Clark* case,—both before the district court and before the circuit court of appeals; and, of course, the Lodge patent, being in suit in that case, was also before both courts. As to the Tesla patent, the defendant in that case argued that—

"This is a complete anticipation of all the fundamentals of the four tuned circuit radio telegraph system of plaintiff's patent, wherein a 'closed' circuit is coupled by a transformer to a grounded antenna at each station." (Brief on appeal for Kilbourne & Clark Mfg. Co., p. 333.)

In view of the foregoing, respondent's argument that the adjudication of validity of the Marconi patent in the *Kilbourne & Clark* (and other) cases is not inconsistent with the result reached below, is clearly erroneous,—the same prior art having admittedly been before both courts.

Regardless of what respondent may say, the fact remains that the Marconi patent was held valid in all of the cases referred to in our petition herein (pp. 4-5) and was held invalid, as to claims 1, 2, 3, 6, 8, 10-14, and 17-20, by the court below.

(b) As to the Fleming patent, respondent is also in error in arguing that the prior *DeForest* case on that patent did not involve "the question of infringement here presented." As respondent admits (brief, p. 7), its alleged infringement consisted in the use of "the DeForest three-element vacuum tubes as detectors and amplifiers." Similarly, the alleged (and adjudicated) infringement in the case of *Marconi Wireless Telegraph Company of America* v. *DeForest Radio Tel. & Tel. Co.*, 236 Fed. 942, affirmed 243 Fed. 566 (Circuit Court of Appeals for the Second Circuit), was the use of DeForest three-element vacuum tubes as detectors.[1]

---

[1]Their use as amplifiers and as generators of oscillations was before the district court only, the adjudication of infringement in those subsequent decrees not having been appealed by defendant. (See p. 22 of our brief in support of our petition for certiorari.)

Again, the fact remains that the Second Circuit Court of Appeals held that claims 1 and 37 of the Fleming patent were infringed by the use of DeForest three-element vacuum tubes as detectors, whereas the court below held directly to the contrary.

(c) It is to be noted that respondent does not suggest that the *evidence* in the present case differs from that in the prior cases, but merely that the positions taken or arguments made by the parties have been different. Thus, respondent's argument is tantamount to saying that, in order to avoid the effect of a prior decision, it is only necessary to make a new argument on the same evidence.

As the issues in the prior cases were the same as in the present case and as the evidence was substantially the same, we submit that there is no sound basis for arguing, as respondent does, that the prior adjudications were not inconsistent with the results reached below.

CONCLUSION

We respectfully urge that plaintiff's petition for a writ of certiorari herein be granted.

Respectfully submitted,

ABEL E. BLACKMAR, JR.,
RICHARD A. FORD,
Counsel for Petitioner.

IN THE

Supreme Court of the United States

OCTOBER TERM, 1942.

Nos. 369 and 373.

MARCONI WIRELESS TELEGRAPH COMPANY, OF AMERICA,
Petitioner and Cross-Respondent,

vs.

THE UNITED STATES,
Respondent and Cross-Petitioner.

BRIEF FOR PETITIONER AND CROSS RESPONDENT

This action was brought by the petitioner and cross-respondent, hereinafter referred to as plaintiff, under the Act of June 25, 1910, as amended by the Act of July 1, 1918, 35 U. S. Code, Sec. 68, claiming compensation because of use by the United States of certain inventions covered by United States Letters Patent.

A final judgment was entered on April 6, 1942 by the Court of Claims of the United States, each side petitioned for a writ of certiorari, and this Court granted the petitions on December 14, 1942.

This brief will discuss the issues on both petitions, because the only issues on the cross-petition relate to one claim of a Marconi patent, other claims of which are among the subjects of plaintiff's petition. Such discussion will avoid unnecessary repetition.

Opinions of the Court Below

The Court of Claims on November 4, 1935, filed its findings of fact and conclusions of law (1 R. 7; 81 Ct. Cl. 671) and its opinion (1 R. 75; 81 Ct. Cl. 741), on the issues of the validity and infringement of the patents; and on April 6, 1942, filed its findings of fact, including among them what previously had been expressed as conclusions of law (1 R. 117) and its opinion (1 R. 157) on the amount of compensation due plaintiff (not yet reported).

There are now only two patents before this Court. Originally, there were four patents in suit: Marconi reissue 11,913, Lodge 609,154, Marconi 763,772 and Fleming 803,684, all of which expired in 1922 or earlier.

The Marconi reissue patent was held not infringed (conclusion of law, 1 R. 75, and finding of fact, 1 R. 117). The Lodge patent was held valid and infringed (conclusion of law, 1 R. 75, and finding of fact, 1 R. 117), the Court finding as reasonable compensation $34,827.70 with interest "as a part of the entire or just compensation" (1 R. 135). Both parties have accepted these decisions, so only the last two patents are in issue here.

The Marconi patent 763,772 was decided to be invalid, except as to claim 16 which was held valid and infringed (conclusion of law, 1 R. 75, and finding of fact, 1 R. 117). This decision is in conflict with the decisions in *Marconi* v. *National Electric Sig. Co.*, 213 Fed. 815 (D. C., E. D. N. Y.); *Marconi* v. *Kilbourne & Clark Mfg. Co.*, 9 Cir., 265 Fed. 644, affirming 239 Fed. 328 (D. C. Wash.); *Marconi* v. *British Radio, etc. Co.* (1911), 27 T. L. R. 274, 28 R. P. C. 18 (4 R. 2525; offered, 1 R. 186) on the corresponding British patent; and *Societe*

Marconi v. *Societe Generale, etc.*, Civil Tribunal of the Seine, on the corresponding French patent (4 R. 2622; offered, 1 R. 202).

The Court of Claims allowed compensation for use of claim 16 of the Marconi patent amounting to $42,984.93 with interest "as part of the entire compensation" (1 R. 156), defendant assigning as error the findings that this claim was valid and infringed, but not the amount awarded if the claim was rightly held valid and infringed.

The Fleming patent was decided by the Court of Claims to be not infringed (conclusion of law, 1 R. 75, and finding of fact, 1 R. 117), and the Court also said in its opinion that the patent was invalid because of delay in filing a disclaimer (1 R. 106, 107), but did not so find. These views are in conflict with *Marconi* v. *De Forest*, 2 Cir., 243 Fed. 560, affirming 236 Fed. 942 (D. C., S. D. N. Y.).

Jurisdiction

The final judgment of the Court of Claims, now sought to be reviewed, was rendered April 6, 1942 (1. R. 117).

The judgment was rendered in an action to recover compensation for the use or manufacture by or for the respondent, the United States, of apparatus embodying the subject matter of four letters patent of the United States. The action was brought under the Act of June 25, 1910, as amended July 1, 1918 (U. S. Code, Title 35, Section 68).

The jurisdiction of this Court is invoked under Sections 3 and 8 of the Act of February 13, 1925, as amended by the Act of May 22, 1939 (U. S. Code, Title 28, Sections 288 and 350). The time to file petition for certiorari was enlarged by order of the Chief Justice of this Court (3 R. 2523).

Statement of the Case

This suit was brought in 1916 by the Marconi Wireless Telegraph Company of America, a New Jersey corporation (1 R. 1), which had then been engaged for several years in the wireless business in this country (Brennan, 1 R. 191, *et seq.*, 2 R. 1347, *et seq.*; Sarnoff, 2 R. 1256, 1273).

In 1919, the Marconi Company conveyed substantially all its assets, except some claims, including the present one, to Radio Corporation of America, which claims the Marconi Company reserved for prosecution, the Radio Corporation advancing the money for such prosecution (1 R. 9-11). The Marconi Company was dissolved in 1920, thereafter acting by trustees in dissolution (1 R. 9), and the claims in the present suit are and for many years have been its only asset.

The taking of testimony commenced in 1917 (1 R. 184-453), and was suspended at the request of the Government until after the war (4 R. 2842-2854), when, because of many claims for the use of radio patents by the Government, an Interdepartmental Radio Board was appointed, consisting of representatives of the Department of Justice, the War Department and the Navy Department, to examine the various patent claims, consider questions of validity, infringement and extent of use, and determine what would be reasonable compensation.

The Board made an exhaustive study of the numerous radio patents submitted to it and thoroughly investigated the entire radio art, examining about 2,500 United States patents, hundreds of foreign patents, and hundreds of United States and foreign publications, and "finally came down to a real serious consideration of 149 patents. This consideration involved searches of the art, writing of long reports, receipt of briefs from claimants, hearings, more

briefs, revised reports, and then an accounting on those patents considered good, which were 27 in number, with much discussion following as to the methods of accounting and the effect of decisions thereon" (hearings before House Committee, 4 R. 2831, 2847; off., 2 R. 1098). On some patents "we did question the validity and made no allowance on them" (chairman of board, hearings before House Committee, 4 R. 2852; off., 2 R. 1098).

The Marconi claim on the four patents in suit was $6,000,000 (1 R. 6), and the Board, after careful analysis of the patents and apparatus (4 R. 2858; off., 2 R. 1098), made a formal report, recommending $1,253,389.02 as compensation (4 R. 2877; off., 2 R. 1098), for $26,399,490.60 of infringing apparatus (4 R. 2823), which is about 4.7%. This report, however, is not in any way controlling in the present litigation, having been made without prejudice.

The report was presented to Congress by the Secretaries of War and the Navy, and the Attorney General, but as no legislation was enacted to carry out its recommendations, the taking of testimony in the present suit was resumed in 1922 (1 R. 453), and concluded in 1930. As customary in Court of Claims cases, a Commissioner was appointed to consider the evidence which had been taken, but another Commissioner succeeded him, who filed a report in June 1933 and the Court of Claims then considered the questions of validity and infringement, there being reserved by stipulation the taking of evidence on the issue of reasonable compensation for the patents found valid and infringed (1 R. 175), and in November 1935 filed its findings, conclusions and opinion (1 R. 7, *et seq.*). Then followed the taking of evidence as to how much apparatus

had been used by defendant which infringed the Lodge patent and claim 16 of the Marconi patent 763,772.

The claims urged in this suit were based upon apparatus purchased and used by the Army and Navy prior to 1920, principally during the last World War. Plaintiff did not know the extent of the infringement and could ascertain and prove the facts regarding it only by records which in the main were secret records of the Army and Navy departments. Before plaintiff could secure the production of such records, it had to identify them from such source records as it possessed or were made available to it by defendant and third parties. Government departments then produced, at plaintiff's request, hundreds of army and navy contracts, together with the files relating thereto, all of which had to be examined to determine the nature of the apparatus called for under the contracts, and whether it was delivered and paid for (1 R. 121). About 100 of these contracts are listed in the record (1 R. 122, 123, 145). This was a lengthy process because naturally the various Army and Navy officers who from time to time were in charge of records relating to the contracts were not primarily interested in the *Marconi* law suit.

The Court of Claims points out (1 R. 174) that defendant in 1940 stated

> "The highly technical character of the subject-matter, the difficulty of assembling competent witnesses, and the time required for preparation by both parties are believed to be such as to indicate reasonable speed by both parties".

Litigation against the Government is not always a speedy process. As appears from *U. S.* v. *Citizens Loan & Trust Co.*, 316 U. S. 209, it took about twenty-three

years to collect a $10,000 insurance policy. In cases such as the present one, where the evidence is taken out of Court, the issues are many and complicated, and defendant relies upon witnesses from the Army and Navy departments, more time is required than in ordinary suits. The submission of evidence on the accounting closed in March, 1940, the Commissioner twice reopened the case to take more evidence, and in 1941 filed his report, the Court of Claims deciding the case in April 1942.

Questions Presented by the Two Writs

1(a) Validity of all claims in suit, except claim 16, of Marconi patent 763,772 (plaintiff's writ). The Court of Claims found that they were invalid.

(b) Infringement of all claims in suit, except claim 16, of the Marconi patent (plaintiff's writ). The Court did not make any ultimate finding of fact on this issue, but intimated in its opinion and findings (1 R. 44, 45, 95, 96, 101) that the claims were infringed, if the claims were valid.

2. Validity and infringement of claim 16 of the Marconi patent (defendant's writ). The Court of Claims found that it was valid and infringed.

3(a) Validity of claims 1 and 37 of the Fleming patent, especially in view of a disclaimer (plaintiff's writ). The Court of Claims said the claims were invalid for delay in filing the disclaimer (1 R. 106, 107), but did not so find.

(b) Infringement of claims 1 and 37 of the Fleming patent (plaintiff's writ). The Court of Claims found that they were not infringed.

The specifications of error on the two petitions present the above points.

Specification of Errors on the Two Writs

Plaintiff in its brief on the petition for a writ urged the following errors by the Court of Claims:

(1) In holding that claims 1, 2, 3, 6, 8, 10 to 14, and 17 to 20 of Marconi patent No. 763,772 were invalid;

(2) In holding that the subject matter of said claims lacked invention;

(3) In holding that the subject matter of said claims, or certain of them, was anticipated in the prior art;

(4) In failing to hold that said claims of Marconi patent No. 763,772 involved invention, that they covered new and useful subject matter, and that Marconi was the first inventor of the subject matter thereof;

(5) In failing to hold that said claims were valid;

(6) In failing to make the ultimate finding of fact that said claims of Marconi patent No. 763,772 were infringed by the apparatus described in the Special Findings of Fact of the Court of Claims, Nos. XLVI, XLVIII, XLIX, and L, of November 4, 1935 (81 C. Cls. 705-710);

(7) In failing to enter a judgment awarding to petitioner compensation for the manufacture and use by and for the respondent of apparatus utilizing the subject matter of claims 1, 2, 3, 6, 8, 10 to 14, and 17 to 20 of Marconi patent No. 763,772;

(8) In failing to hold that claims 1 and 37 of Fleming patent No. 803,684 involved invention, that they covered

new and useful subject matter, and that Fleming was the first inventor of the subject matter thereof;

(9) In failing to hold that said claims of the Fleming patent were valid;

(10) In holding that said claims of Fleming patent No. 803,684 were not infringed by the apparatus described in the Special Findings of Fact of the Court of Claims, Nos. LXXV, LXXVI, LXXVIII, and LXXIX, of November 4, 1935 (81 C. Cls. 735-740);

(11) In failing to hold that said claims of the Fleming patent were infringed by the apparatus described in said findings Nos. LXXV, LXXVI, and LXXIX, and that claim 1 of said patent was infringed by the apparatus described in said finding No. LXXVIII;

(12) In failing to enter a judgment awarding to petitioner compensation for the manufacture and use by and for the respondent of apparatus utilizing the subject matter of claims 1 and 37 of Fleming patent No. 803,684.

Defendant in its petition for a writ urged the following errors by the Court of Claims (defendant's cross-petition for writ, p. 10):

(1) In finding as an ultimate fact that claim 16 of the Marconi patent was valid and was infringed, without first determining its scope in view of the prior art.

(2) In failing to make a finding of fact as to the particular advantage achieved by the shunt condenser in the open antenna circuit of the Marconi patent, and in making a finding of infringement in the absence of such finding.

(3) In failing to find as a fact that the disclosure of the Marconi patent upon which claim 16 is based did not possess the principal advantage of cross-petitioner's structure but possessed a different advantage not used by cross-petitioner.

(4) In basing compensation upon the principal advantage present in cross-petitioner's structures, when such advantage was not disclosed or attained in the patent in suit.

(5) In not revising its findings of fact to conform to the entire evidence in the case where evidence necessarily admitted in the accounting proceedings, to establish a basis for compensation, disclosed incompleteness and error in the findings of fact theretofore made in relation to the infringement of claim 16 of the Marconi patent (No. 763,772).

Summary of Argument

1. This Court can review questions of law, including whether there is a lack of substantial evidence to sustain a finding of fact, whether an ultimate finding or findings are not sustained by the findings of evidentiary or primary facts, and whether there was a failure to make any finding of fact on a material issue.

2. The broad claims of the Marconi patent, which the Court of Claims decided were invalid for want of invention, are valid. The contribution of the Marconi patent to the practical art was of great value, it was made in the obscure and mysterious pioneer days of wireless communi-

cation, no one had previously taught or employed the principle of the patent, and the opinion in 1935 of the Court of Claims that this principle should have been obvious in 1900 to those then skilled in the art was erroneous.

3. The broad claims of the Marconi patent were infringed, and the Court of Claims should have so found, sufficient basis for such finding being present in the opinion and findings of that Court.

4. Claim 16 of the Marconi patent was valid and was infringed, as the Court of Claims rightly found. This claim describes a specific connection of elements for using the broad invention of the other claims, which connection was new and highly useful.

5. The Fleming patent was the pioneer patent in the radio tube art and its principles have been widely employed. The Court of Claims should have found the claims in suit valid over the prior art, instead of failing to make any finding on this point.

6. The Fleming patent was infringed by detectors, amplifiers, and oscillators, using three-electrode tubes and the Court of Claims was wrong in finding that there was no such infringement.

7. The Fleming patent was not invalid because of unreasonable delay in filing a disclaimer, and the Court of Claims should have so found, instead of failing to make any finding on this point and saying in its opinion that the patent was invalid for such reason.

ARGUMENT

I. This Court can review questions of law, including whether there is a lack of substantial evidence to sustain a finding of fact, etc.

The Act of February 13, 1925, U. S. Code, Title 28, Section 288, was amended by the Act of May 22, 1939, to authorize this Court in cases before it by certiorari to the Court of Claims

> "to review, in addition to other questions of law, errors assigned to the effect that there is a lack of substantial evidence to sustain a finding of fact; that an ultimate finding or findings are not sustained by the findings of evidentiary or primary facts; or that there is a failure to make any finding of fact on a material issue" (Act of May 22, 1939).

Prior to this amendment this Court could not review such matters, as was held in *U. S.* v. *Esnault-Pelterie*, 303 U. S. 26 (January 31, 1938):

> "The argument that the Government is precluded from obtaining the sort of review which is permissible in this Court, when there is a conflict between circuit courts of appeals as to validity and infringement of patents, and the questions are submitted upon the evidence taken in the District Court, is unavailing, for the result is due to the procedure which has been established by the Congress for the determination of claims against the United States" (p. 32).

Thereafter the Act was amended, as above set forth, to permit such review.

In the present case, there was substantially the same evidence before the Court of Claims as there was before

the circuit courts of appeals with which it disagreed. The vital issues are whether the patents, written contracts between the patentee and the Government, should be sustained as enforceable, and whether their meanings are such that the complained of apparatus are infringements of the legal rights conveyed by the patents. The only questions presented by the two writs are questions as to the correctness of the decisions by the Court of Claims, on the record before it, and its failure to make findings of fact upon material issues.

II. The Marconi patent 763,772 was valid as to the broad claims.

The Court of Claims in 1935 decided that the Marconi patent was invalid, except as to a narrow claim 16 (1 R. 75), because the Court thought that in 1900, when Marconi made his invention, "one skilled in the art", having knowledge of the Tesla and Lodge patents and the Stone documents, would make the same invention (1 R. 99).

It may be helpful here to state briefly the nature of wireless communication.

A. The nature of wireless communication.

The nature of wireless communication is explained in the record (Waterman, 1 R. 309 *et seq.*) and may be briefly described as follows.

Wireless communication is by the so-called ether, which serves as the medium through which wireless waves travel from a transmitting station to a receiving station. The ether (wireless) waves, often termed Hertzian waves, because of the 1888 discoveries of Hertz, are of the same nature as light waves, heat waves, and X-rays, their different effects

being due to the fact that the lengths of the waves are different.

A wireless transmitter is like a lighthouse, emitting light of an invisible nature, which is intercepted by a receiving station, where is absorbed and used the minute portion of energy reaching the station. The transmitter produces waves in the ether, which waves radiate out from the transmitting antenna, and are intercepted by receiving antennas.

Each signal radiated from a transmitting, or sending, station is made up of either a series of groups or a train of waves, of high or radio frequencies (from about 15,000 up to several millions of cycles per second), which are interrupted or modified in accordance with some signal at an audio frequency (below 15,000 cycles per second)—telegraph dots and dashes, sound waves, etc. During the accounting period, the signals were almost exclusively telegraph signals. The radio waves may be either one of two kinds: spark waves (created by a series of electric sparks) or continuous waves.

In the case of spark waves, each spark creates a comparatively short train of radio waves, and each telegraph signal, whether dot or dash, comprises a group of sparks, a short group for a dot and a longer group for a dash. In the case of continuous waves, each signal is made up of a train of radio waves, the length of the train determining whether the signal is a dot or a dash. Spark waves can be heard (detected) at a receiver by providing apparatus which is responsive to each group of waves, since the group-frequency is always an "audio" frequency, that is, a frequency within the range of frequencies that are audible to the human ear. Continuous waves must be modified either at the transmitter or at the receiver, so that each train of waves is made to vary at an audio frequency.

Audio frequencies, from about 15 cycles to 15,000 cycles per second, are too low for effective communication through the ether; therefore, the signals must be "carried" by high or wireless frequency waves.

Currents of radio frequencies are impressed upon the transmitting antenna, the currents produce waves of corresponding frequency in the surrounding ether, and the waves spread out in all directions.

At the receiving station, a minute portion of the ether waves is intercepted by another antenna, thereby producing radio frequency currents in the circuits of the receiver, which currents have the same frequency characteristics as the waves (and as the currents at the transmitting station). In the case of spark waves, the radio currents are rectified or otherwise integrated into the group or audio frequency, and the resultant currents applied to some kind of device which is responsive to the audio frequency so that the original signals may be detected. In the case of continuous waves, the radio currents are modified or broken up at audio frequencies so that, while the waves are being received, an audible or other indication of that fact enables them to be detected.

As is apparent from the foregoing, the receiving process is essentially the reverse of the sending process. Simply, in sending, radio frequency currents are produced and are broken up into signal frequencies; these currents are applied to an antenna and the signal-carrying radio waves are radiated. In receiving, the ether waves are applied to an antenna to produce signal-carrying radio frequency currents; the signals are then separated from the radio currents to obtain signal currents, which are used to operate an indicator.

B. The state of the wireless telegraph art prior to the Marconi patent.

The history of the art prior to the Marconi patent is well stated in the opinion in *Marconi* v. *National El. Signalling*, 213 Fed. 815 (D. C. E. D. N. Y.), the latter opinion being referred to with approval in the *Kilbourne & Clark* decisions, 265 Fed. 665 and 239 Fed. 329.

Marconi in 1894 learned of the Hertz 1888 experiments and in 1896 filed an application in the United States, upon which was granted the patent which was reissued as 11,913. That patent, formerly in suit, described a sending station and a receiving station, without any tuned circuits.

This system would operate, but only at short distances, because there was too much waste of energy. The transmitting antenna would quickly, and not persistently, radiate the energy applied to it, with the result that the train of ether waves would be too short instead of being sustained. And at the receiving station, the antenna likewise would quickly absorb the received waves, instead of storing them up, and the antenna also would receive undesired waves from other transmitting antennas (Waterman, 1 R. 328 *et seq.*; *Marconi* v. *National*, 213 Fed. 847). The Lodge patent formerly in suit was an improvement, both the transmitting and the receiving antennas being tuned with inductance, so that each would vibrate longer and the receiver would be more selective (inductance in an electrical system is the same as inertia in a physical system). But even with the Lodge patent, signalling to only short distances, about eighty miles, was possible before the invention of the Marconi patent 763,772, which enabled communication in 1901 over a distance of more than 6,000 miles (Marconi, 1 R. 532; *Marconi* v. *National*, 213 Fed. 848).

Patents for Marconi's second invention were granted in England, France and this country, which were sustained by the courts in bitterly contested litigation. And the United States Patent Office did not casually grant the patent.

C. The Patent Office history of the Marconi patent.

The application for the Marconi patent received a very intensive and almost hostile examination by the Patent Office, and was granted only after unusually careful investigation. This was not a case where a patent application slipped through with only slight attention by the Patent Office.

The application was filed in November 1900, and was rejected in December on Lodge (British patent corresponding to Lodge 609,154, formerly in suit) and Marconi 586,193 (which became reissue 11,913). The application was amended in details unimportant here, and the Patent Office examiner then required explanation of the operation of the two transmitting circuits (action of August 12, 1901; 5 R. 3985; off., 2 R. 1226), because even he, although an expert in the wireless art through his study of many patents, did not understand how it could operate (the Court of Claims in 1935 considered the Marconi system simple and obvious). Some detail amendments were made and the operation of the system explained to the Patent Office examiner (*id.*, p. 3989).

In February, 1902, the application was rejected on Lodge and several Marconi, Braun and other patents (*id.*, p. 3992), an affidavit of Marconi being submitted in reply that Marconi had not made the invention when he invented his earlier patent, 627,650, etc. (*id.*, p. 3999),

as Marconi also testified (1 R. 562, 563). The claims were then rejected on the Tesla patent 649,621, a division of the Tesla patent 645,576 (*id.*, p. 4002).

This rejection was on June 3rd, 1902 and the one year period then allowed for reply elapsed without reply. On October 6, 1903, the Commissioner of Patents was petitioned to permit a reply because of absences of Marconi, etc., which was opposed by the Examiner, denied by the Commissioner, reconsideration asked, upon the basis of affidavits by Marconi and his attorneys, and granted in March 1904 (*id.*, pp. 4066, *et seq.*).

The Patent Office then rejected some claims on Stone 714,756, allowing other claims (*id.*, p. 4068), the applicant amended some claims and cancelled others (*id.*, p. 4070) and the patent was granted.

These Patent Office proceedings are referred to by the Court of Claims in its findings (1 R. 38, 55) and in its opinion (1 R. 94), pointing out that four claims in the application were cancelled because of the Stone patent, the present claims 4, 5 and 7 of the patent being substituted. But those claims are not in suit and the cancellation is not material to the question of whether the claims in suit are valid or are infringed. Marconi made broad claims to tuned circuit apparatus, which claims are in suit, and also narrower claims, and the examiner allowed the claims over the Stone and other references.

It is plain from this brief summary that the Patent Office gave very careful and thorough consideration to the Marconi application before finally granting it. And while it is recognized that the conclusions of the Patent Office that a patent should issue to Marconi for what he disclosed, different from the earlier Marconi, Lodge, Tesla,

MARCONI AND TESLA SYSTEMS

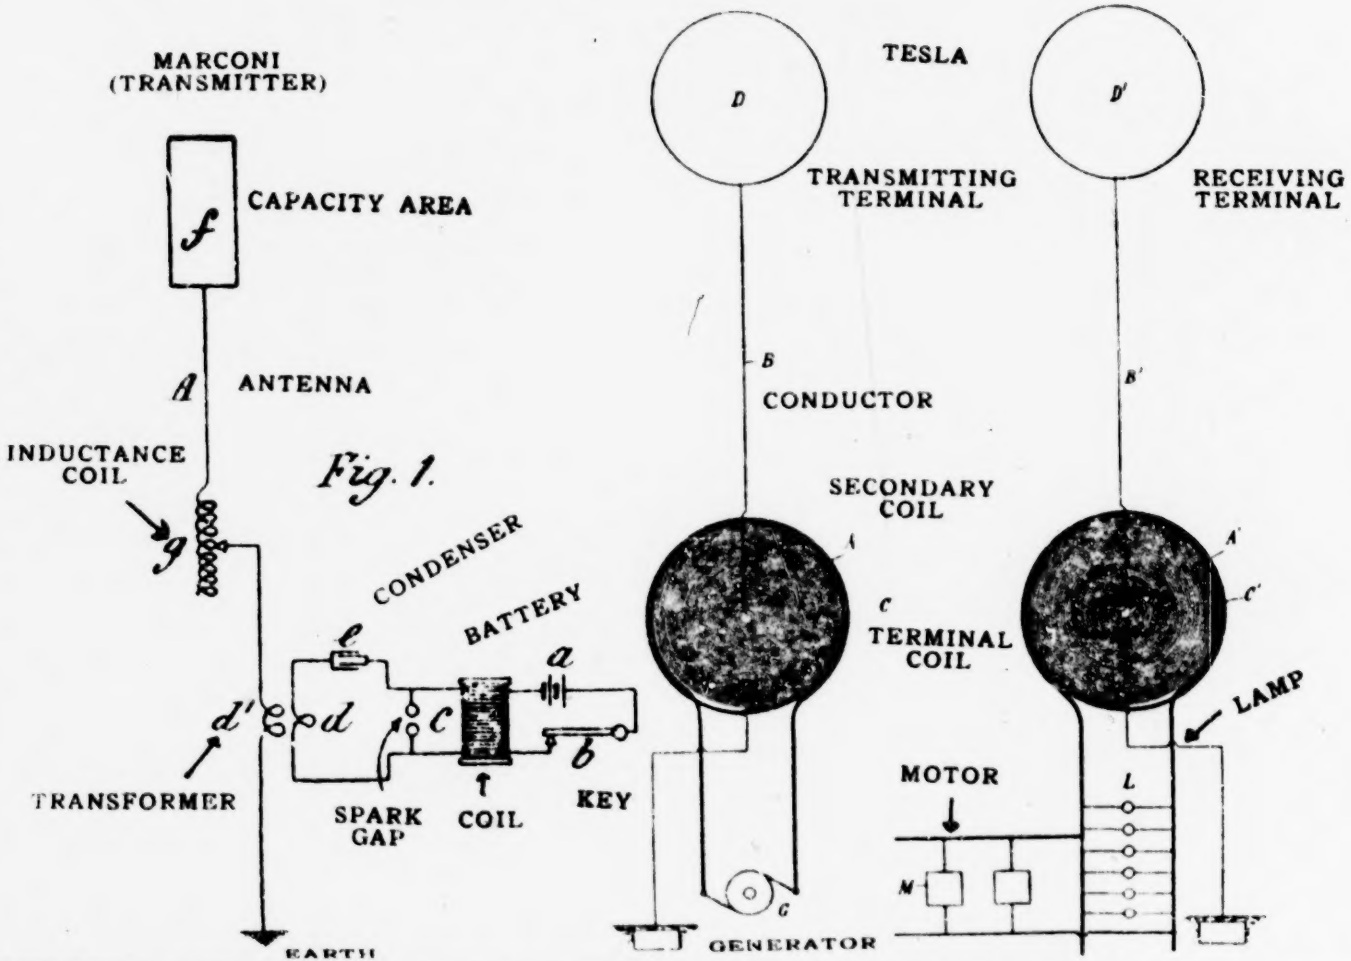

Fig. 1.

18-a

and other patents, is not controlling on the courts, surely the decisions of that administrative body of experts are entitled to some weight.

D. A description of the Marconi patent.

The Marconi patent (4 R. 2588; off., 1 R. 186) discloses transmitting and receiving circuits. For convenience, there are reproduced on the opposite page, diagrams of the Marconi transmitter and of Tesla patent 645,576, relied upon by the Court below.

Referring to Marconi's Fig. 1 (the transmitter), there are two circuits in which the radio frequency currents flow: the antenna circuit (elevated wire connected to ground, containing an inductance coil, g, and one coil, d', of a two-coil transformer) and the oscillation producing circuit (other coil, d, of the transformer, condenser, e, and spark gap). When the telegraph key, b, is pressed, current from the battery, a, flows through the primary of the induction coil, c, being broken up unto pulses by a vibrator (not shown in this patent but shown and described in the reissue patent 11,913; 4 R. 2567; off., 1 R. 190).

The pulsating current is transformed to a much greater voltage by the induction coil, c, and applied to the spark-gap circuit where, by the action of the elements therein, one group of radio frequency oscillations is produced by each pulse of battery current. The oscillations are then transferred to the antenna circuit and radiated therefrom as ether waves. Thus there are two separate radio circuits, the oscillation producing circuit and the antenna circuit. The antenna is a wire with widely separated ends; as the ends are not connected together, the antenna circuit is referred to as an open circuit. The oscil-

lation producing circuit is closed. The open and closed circuits are tuned to the same frequency.

The receiving system of Fig. 2 also has an open circuit and a closed circuit, tuned to the same frequency. The antenna circuit is open like the antenna circuit of Fig. 1, with the addition of a shunt condenser h (subject of Marconi claim 16) and some details unimportant here. There is a closed circuit, coupled to the antenna circuit by a two-coil transformer (pat. p. 2, l. 77 *et seq.*), to which are connected various things which enable the signals to be detected, such as "a telegraphing instrument or a printing device" (pat. p. 2, l. 113). Other detectors are also mentioned (p. 2, l. 56, *et seq.*)

The patent is plain in its description of the invention (Waterman, 1 R. 338 *et seq.*). As stated on page 1, ll. 37-55, the transmitter includes "a persistent oscillator, and a good radiator" (the oscillation producing circuit and the antenna circuit), and the receiver has "a good absorber of electrical oscillations, while a device responsive to electric waves, such as an imperfect contact or a device for operating the same, is included in a circuit" (the antenna circuit is the "absorber"). Marconi tunes the two circuits at the transmitter (and also at the receiver) "to be the same or octaves of each other" (pat., p. 2, l. 128; p. 3, l. 12 *et seq.*).

Again

> "The illustrated arrangement of parts at a transmitting-station enables much more energy to be imparted to the radiator f, the approximately closed circuit of the primary being a good conserver and the open circuit of the secondary being a good radiator of wave energy. My experiments have demonstrated that the best results are obtained at the transmitting station when I use a persistent oscilla-

> tor—an electrical circuit of such a character that if electromotive force is suddenly applied to it and the current then cut off electrical oscillations are set up in the circuit which persist or are maintained for a long time—in the primary circuit and use a good radiator—i.e., an electrical circuit which very quickly imparts the energy of electrical oscillations to the surrounding ether in the form of waves—in the secondary circuit" (pat. p. 2, ll. 6-25).

Transmitting systems prior to Marconi included the spark gap or other means for producing oscillations (high frequency currents) in the antenna circuit, which arrangements reduced the current in that circuit, because of the resistance of the spark gap. Marconi removed the spark gap from the antenna circuit and put it in an auxiliary circuit, which could be tuned to a high degree, thus greatly strengthening the oscillations produced. Thus two of the necessary functions of a transmitting system were greatly improved, namely, the production of oscillations and the radiation into space of ether waves caused by the oscillations. More energy can be produced in a closed circuit than in an antenna circuit, which has great resistance and little capacity, while the closed circuit is not so limited, and also, by reason of the resonant nature of the circuits, the energy can be efficiently transferred from the closed circuit to the open antenna circuit while the latter is radiating the ether waves into space (Waterman, 1 R. 347, 348).

In the similar two circuits of the Marconi receiving system, the tuning, which was essential in order to build up by resonance the extremely weak received signals, and also to discriminate against undesired electrical energy, caused by atmospheric conditions or undesired stations, was greatly improved.

The invention is well described in the British decision (4 R. 2525) and in the *National* opinion, 213 Fed. 847, 848. It immediately went into wide use, continued, with alterations only in the auxiliary apparatus, in almost exclusive use throughout the entire period covered by the record in this case, and has been appraised as one of high order by all courts which passed upon it in the early days of wireless; *National* case (213 Fed. 841), a "conspicuous advance in wireless telegraphy" (p. 858); *Kilbourne & Clark* case (239 Fed. 328), "a real accomplishment" and the ideas involved in the patent "have proven of great value to the world" (pp. 335, 342); High Court of Justice, Chancery Division, "an entirely new and useful result" (4 R. 2557); and the Civil Tribunal of the Seine, in France, "a new and very important industrial result" and "a wonderful conquest" (4 R. 2641) and "the Marconi patent stands out as an unassailable monument until new discoveries are made" (4 R. 2674).

E. The claims of the Marconi patent.

The Court of Claims correctly points out (1 R. 32) that the claims in suit may be divided into three classes, transmitter claims 1, 3, 6, 8, 11, and 12, receiver claims 2, 13, 14, 16, 17, 18 and 19, and combined transmitter and receiver claims 10 and 20. All these claims, except claim 16 for a specific type of receiving circuit, were held invalid by the Court of Claims, because of certain Tesla and Lodge patents and Stone documents (opinion, 1 R. 99).

In addition, the Court said that receiving claims 2, 13, 18 and 19 were also invalid, because they were not limited to the circuits being in tune with each other, and were anticipated by an earlier Marconi patent 627,650 (finding LIX, 1 R. 57). This was erroneous, because the descrip-

tion in the specification states that the circuits are so tuned, and claims are read in the light of the specifications, especially when they refer to them, as do the claims here, *Seymour* v. *Osborne*, 11 Wall. 516, 547; *Carnegie Steel* v. *Cambria*, 185 U. S. 403, 432. To the same effect is *Marconi* v. *Kilbourne & Clark*, 239 Fed. 328, 342 (D. C., Wash.), stating with respect to the Marconi patent:

> "The application not being for the principle of resonance or tuning, or such foundation as a scientific fact, reference to specification may be made for interpretation of claims made. *Tilghman* v. *Proctor*, 102 U. S. 707, 26 L. Ed. 279."

Upon such reference being made, it is plain that these specific claims describe the tuned circuits of the Marconi patent, and were valid, as indeed the Patent Office concluded in allowing them over the earlier Marconi patent, which was considered by the Patent Office (5 R. 3933; off., 2 R. 1226).

The real question is whether these and the other broad claims were invalid for lack of invention, as the Court of Claims concluded.

Claim 6 is a typical claim for transmitting circuits and claim 14 is a typical claim for receiving circuits. They are as follows:

> "6. At a transmitting-station employed in a wireless-telegraph system, the combination of a transformer whose secondary is connected to an open circuit including a radiating-conductor at one end and capacity at the other end, and whose primary is connected to a condenser-circuit discharging through a means which automatically causes oscillations of the desired frequency, and means for adjusting the oscillation period of each of the two circuits connected

with the transformer to bring them into accord with each other, substantially as described."

"14. At a receiving-station employed in a wireless-telegraph system, the combination of an oscillation-transformer, an open circuit connected with one coil of said transformer, said circuit including an oscillation-receiving conductor at one end and capacity at the other end, a wave-responsive device electrically connected with the other winding of the oscillation transformer, and means for adjusting the two transformer circuits in electrical resonance with each other, substantially as described."

F. The Tesla, Lodge and Stone prior art.

In considering the patents urged against the Marconi patent, it is important to appreciate that they were disclosures and teachings as of their date, and not of today. There are now thousands of radio engineers, and probably great numbers of high school boys, who could take almost any early radio patent and, selecting a part, combine it with some parts from other radio patents, so as to produce a modern device. But that is because before they saw the patents they had been educated so that they knew the right thing to do. Problems once solved are not difficult, and there are many things which seem plain, natural and obvious after they have been done. It is easy to look back and see what should have been done—it is another matter to select the right course in an uncharted sea.

The Court of Claims based its views (finding, 1 R. 59; opinion, 1 R. 96 *et seq.*), that the broad claims of the Marconi patent were invalid, on the Tesla and Lodge patents and Stone documents, reproduced in the record here. It is not quite clear whether the Court thought that the Tesla

patents alone fully anticipated the Marconi claims, or whether a combination of Tesla, Lodge and Stone made the Marconi claims invalid because their subject matter was or should have been obvious to those in the radio art of that day. In either case, on a fair reading, these papers do not support the Court's conclusion.

1. *The Tesla patents.*

The Tesla patents 645,576 and 649,621 are based on a patent application filed September 2, 1897, which was divided, the first patent issuing on the original application and the second patent on the divisional application. The two patents describe the same method and apparatus, having the same illustrative drawings, method claims being in the original patent and apparatus claims in the divisional patent (5 R. 3602, 4089).

Although the proposed method is, in a broad sense, a "wireless" method, it is not one using radiated (Hertzian) ether waves, and the apparatus is not intended for or useful in such a system.

The Marconi and all other useful wireless systems operate by an antenna producing ether waves, which radiate out through the nonconducting and insulating air until they meet an antenna which converts them into currents. As distinguished from this, Tesla proposes to electrify the air, changing it from a non-conducting condition to a conducting state, so that currents at the sending station will run across the conducting air strata, as along a wire, to the receiving antenna. The electrification was to be accomplished by producing very high voltages, millions of volts, at the top of the transmitting antenna.

The Tesla apparatus was designed to carry out this method, and as we shall show, it was adapted to produce

large currents and high voltages, but not to perform in a Hertzian wave or radiation system.

Even a casual reading of the original patent 645,576 (5 R. 3002) discloses its Jules Verne nature.

The patent commences with some observations on the so-called Crookes tube, containing gas, which, when rarefied and electrified by a high voltage, became conducting so that it would carry a current. From this Tesla concludes that gases conduct better when electrified and that "the conductivity imparted to the air or gases increases very rapidly both with the augmentation of the applied electrical pressure and with the degree of rarefaction" (p. 1, ll. 65-69). For example, says Tesla (p. 2, l. 80) "it has long been known or surmised that atmospheric strata at great altitudes—say fifteen or more miles above sea-level, are, or should be, in a measure, conducting" (a something less than positive statement).

However, as Tesla could not reach this extremely rarefied and high strata, he proposed to electrify lower strata, and thus make them conducting, even better than "a copper wire of a practicable size" (pat. p. 3, l. 101), by using a high antenna with millions of volts at its top. For example, the patent says that using antennas of about thirty to thirty-five thousand feet high and electrical pressures of fifteen or twenty million volts, "the energy of many thousands of horse-power may be transmitted over vast distances, measured by many hundreds and even thousands of miles" (p. 4, l. 132, *et seq.*).

The Tesla patents are plain that they describe a current-conducting method and not radiation of ether waves. The original patent distinguishes its method "from other known methods of transmission . . . based, in so far as the

atmosphere is concerned, upon those qualities which it possesses by virtue of its being an excellent insulator" (p. 2, l. 65, *et seq.*), namely, a non-conductor, as it is in radio communication. The same statement is expressed in the divisional patent in different words (p. 2, l. 73, *et seq.*) as follows:

> "It is to be noted that the phenomenon here involved in the transmission of electrical energy is *one of true conduction* and *is not to be confounded with the phenomena of electrical radiation* which have heretofore been observed and which from the very nature and mode of propagation would render practically impossible the transmission of any appreciable amount of energy to such distances as are of practical importance."*

Turning now to the apparatus by which Tesla produces the very large currents to carry the energy and also the millions of volts to make the air strata conducting:

This apparatus is shown in the single drawing of both Tesla patents. No tuning is shown in the drawing. Referring first to the original patent, which contains the fullest description, its explanation of the drawing does not contain a word about tuning (p. 2, l. 122 to p. 3, l. 85). There is a primary circuit, containing a source of alternating currents, G, and a coil C, which is the primary coil of a transformer. There is also a secondary circuit, which is an open circuit, containing a vertical conductor B with an upper terminal D and a coil A, which is the secondary of the transformer. Energy in the primary circuit may be transferred across the transformer to the open circuit. By this apparatus, large currents of fairly high voltage are pro-

*Italics in quotations are ours throughout unless otherwise stated.

duced in the primary circuit, and are transformed into currents of much higher voltages in the wire, whose terminal D electrifies the air strata, along which the currents run to a similar receiving system.

If Tesla had considered that tuning was essential, or even important, to producing his currents or voltages, he would have said so in describing this apparatus.

However, the patent also describes "a model plant which has been long in use and which was constructed for the purpose of obtaining further data to be used in the carrying out of my invention on a large scale" (p. 3, l. 108, *et seq.*), and this very peculiar experimental device did have a kind of tuning. This apparatus comprised a fifty foot tube of rarefied air, with a transmitting terminal in the tube at one end and a receiving terminal at the other end of the tube. The voltage in the primary circuit was 50,000 volts, the primary coil had one turn, the secondary coil had fifty turns and the secondary voltage was 2,500,000 volts (fifty times 50,000), the voltages at the terminals being "from two to four million volts" (p. 4, l. 30). In connection with this fifty foot, several million volt, apparatus, tuning is referred to. Tesla proposed tuning the circuits, to produce high voltage to electrify the air, but not to increase the currents nor for any other purpose.

> "The primary and secondary circuits in the transmitting apparatus being carefully synchronized, an electromotive force from two to four million volts and more was obtainable *at the terminals*" (Tesla pat., p. 4, l. 27, *et seq.*).
>
> "The results were particularly satisfactory when the primary coil or system A', with its secondary C', was carefully adjusted, so as to vibrate in synchronism with the transmitting coil or system AC" (p. 4, l. 40, *et seq.*).

> "The high electromotive force obtained *at the terminals* of coil or conductor A was, as will be seen, in the preceding instance, not so much due to a large ratio of transformation as to the joint effect of the capacities and inductances in the synchronized circuits" (p. 4, l. 60, *et seq.*).
>
> "a transmitting and receiving coil, or conductor, both connected to the ground and to an elevated terminal and adjusted so as to vibrate in synchronism" (p. 5, l. 49, *et seq.*).

The plain purpose of this synchronization (tuning) was to produce the millions of volts which Tesla thought would make conductive the high air strata. There was no tuning of the wire circuit to produce more powerful ether waves or a more selective ether wave (Tesla repudiates ether waves). Indeed, the great length of the wires proposed by Tesla, "thirty to thirty-five thousand feet above the level of the sea", which was "a comparatively-small elevation" (Tesla pat., p. 5, il. 2-4), would prevent tuning (Weagant, 2 R. 1641; Hogan, 3 R. 1862; *National* opinion, 213 Fed. 847).

The Tesla divisional patent has a shorter description of what was in the original patent, and contains claims to the apparatus described in the original patent. There is nothing in this patent concerning tuning one antenna circuit to another circuit in the same system, but only to tuning the transmitting circuit as a whole to the receiving circuit (p. 1, l. 98, *et seq.*).

The Court of Claims says (finding, 1 R. 39) that the Tesla original patent

> "instructs those skilled in the art that the open and closed circuits of the transmitting system and the open and closed circuits of the receiving system of

the Tesla patent, should be in resonance with each other, or, in other words, that all four circuits should be in resonance.

"Such teaching is further implied in Tesla patent #649,621, based on a divisional application of the above-named Tesla patent in which it is stated, beginning with line 97, page 1, that 'it will be readily understood that when the above-prescribed relations exist the best conditions for resonance between the transmitting and receiving circuits are attained, and, owing to the fact that the points of highest potential in the coils or conductors AA' are coincident with the elevated terminals the maximum flow of current will take place in the two coils, and this, further, necessarily implies that the capacity and inductance in each of the circuits have such values as to secure the most perfect condition of synchronism with the impressed oscillations.'"

The vital error in the Court of Claims' reasoning was that it did not understand that Tesla synchronizes only for the purpose of obtaining his tremendously high voltages, at the terminals, so that the air could be made conducting. For example, in the divisional patent, the system and apparatus is described without a word concerning tuning (resonance) except the portion above quoted in the court's finding, and there Tesla is referring to his specific example, composed of "the above-prescribed relations" in which there is not a word regarding tuning. The "relations" include "a secondary of fifty miles in length", and adjusting the length of wire so that "the points of highest potential are made to coincide with the elevated terminals DD'" (p. 1, l. 88, *et seq.*). There is not a word about the two things which determine tuning, namely, capacity (condensers)

and inductance (coils), but only the frequency of the currents, the potential and the length.

The Court of Claims also says (opinion, 1 R. 97):

> "Just what method he [Tesla] proposed to use for synchronizing the circuits is not stated, but Lodge had shown how it could be done by the system of adjustable inductance and as we have specially found (see Finding LXII), anyone skilled in the art was capable of applying the Lodge method of tuning to the Tesla system."

The Court of Claims said after the Tesla and Lodge patents "were issued it was only necessary to put them together to have the Marconi system" (opinion; 1 R. 98). But the Patent Office and the other courts were right in concluding otherwise, especially as the Tesla ideas would not have appealed to an intelligent reader, who would doubt the extraordinary statements made by Tesla that it was possible by his system to transfer electrical energy "in quantities suitable for industrial uses on a large scale up to practically any amount and, according to all the experimental evidence I have obtained, to any terrestial distance" (pat., p. 2, l. 60, *et seq.*), this being based on experiments with a fifty-foot tube (*id.*, p. 4, l. 14).

In the French litigation, the decision considered the Tesla French patent corresponding to the United States Tesla patents here (4 R. 2661 *et seq.*) and also the Tesla patent 645,576 (p. 2688), with respect to which the court says (p. 2672)

> "whereas doubtless vague references are made therein to the transmission of intelligible messages, but the language being, so to speak, with evident intention couched in vague terms, cannot be considered as imparting to the patent the character of a wireless telegraphy invention; moreover it is diffi-

> cult to see how a device capable of conveying currents at a high voltage, and intended for continuous lighting or motive action, could be made suitable to the special requirements of transmitter and receiver, providing the intermittent but repeated action requisite for the working of wireless telegraphy with manipulators;"

In the *National* decision, 213 Fed. 815, Tesla is discussed and it is pointed out that his antenna could not be resonant, although the transformer might, and that "Tesla's conception seems to be entirely remote from the subject-matter of the patent in issue" (p. 857).

In the *Kilbourne & Clark* opinion in the district court, 239 Fed. 328, Tesla's book and his patent 649,621 are referred to (pp. 334, 337), but the court sustained the claims of the Marconi patent, saying (p. 335): "To reconcile persistency of oscillations and amplitude of vibration in the radiator was a real accomplishment." The appellate court's opinion refers to the Patent Office consideration of the Tesla patents (265 Fed. 659) and says (661): "we find that the claims of the [Marconi] patent may be sustained for the combination of elements such as are found typical in claims Nos. 6, 14, 10 and 20 for both transmitting and receiving apparatus."

The Tesla patents did not describe the invention of the Marconi patent, they did not teach it to anyone, they did not lead to anything practical, and they did not anticipate or invalidate the Marconi patent.

2. *Lodge.*

The Lodge patent 609,154 (4 R. 2579; off., 1 R. 190) was applied for and issued in 1898, and describes a wireless communication system, operating by Hertzian waves.

The invention consisted in tuning the antenna, by means of an inductance coil, so that the transmitting antenna would transmit longer trains of waves and also the length of the waves would be increased. Thus interference between messages can be greatly reduced (Waterman, 1 R. 330, *et seq.*).

The Lodge patent describes in Fig. 1 a single-circuit transmitting antenna and a single-circuit receiving antenna, each being tuned. Fig. 4 is a tuned transmitting antenna circuit with a closed coupled circuit, *not tuned*, and Fig. 13 is a tuned receiving antenna, with a coupled closed circuit, *not tuned* (Hogan, 1 R. 1864; Weagant, 2 R. 1629; Waterman, 3 R. 1929; *National* opinion, 213 Fed. 857).

Sir Oliver Lodge was a great scientist, who knew as much as, if not more than, any other worker in the radio field. He was thoroughly familiar with Hertz's work, believed that Hertzian waves could be satisfactorily utilized, made many experiments on radio waves, and delivered lectures in 1894 on this subject, including discussions of transmitting and receiving antennas, tuned circuits, etc., (deft's ex. E-4, 5 R. 3872; off., 2 R. 867).

But Lodge did not make the Marconi invention, and the sensible view of Lodge's work is that it establishes, not negatives, invention in what Marconi did.

The British court referring to the Lodge patent, said (4 R. 2546)

> "This, in my opinion, is exceedingly strong evidence that Marconi's 1900 invention was not so obvious as to deprive it of subject matter Here was Lodge, an electrical engineer of first rate ability, actually devising means to get over the difficulty he had himself explained in his first lecture (1894), the

> difficulty that a good radiating or absorbing circuit is a bad oscillating circuit and a bad conserver of energy. To get over this difficulty, he is making a compromise at both ends by partially sacrificing the radiating or absorbing qualities of his aerial. He introduces two circuits at the receiving end, and yet he does not see that if only he utilized the principle of resonance, as between those two circuits the problem would be solved, at any rate at the receiving end, and really the problem at the transmitting end is the same problem from the reverse point of view. The common knowledge of the art was so far as material for the present purpose, the same when Lodge prepared his 1897 specification as when Marconi prepared his 1900 specification. How then can I treat as obvious at the latter date what so able a man as Lodge entirely failed to see at the former date".

The fact that Lodge did not see the desirability of tuning his closed circuit is very convincing that it was not as obvious in 1900 as the Court of Claims in 1935 thought it should have been.

3. *Stone.*

The Stone patents 714,756 and 714,831 (5 R. 3648, 3667; off., 2 R. 865) were considered by the Patent Office before granting the Marconi patent (1 R. 38), and they, with perhaps some letters from Stone to a friend, are relied upon by the Court of Claims (1 R. 99, 100).

Stone believed that an antenna necessarily radiated a complex wave, that is, a wave containing simultaneously a considerable number of different frequencies. He proposed to cure this defect by producing a simple wave in a tuned closed circuit and forcing this simple wave on an untuned antenna, so that the waves emitted by the antenna would be

controlled, as to form, solely by the characteristics of the closed circuit, regardless of the characteristics of the antenna. On the other hand, Marconi, while using a closed tuned circuit in which the currents are produced, also tunes the antenna circuit so that the currents are built up in it and greatly amplified by resonance.

Similarly, at the receiving station, Stone has an untuned antenna and Marconi a tuned antenna, and each has an associated closed circuit tuned to the frequency of the oscillation producing circuit at the transmitter.

(1) *The Stone antenna circuit was not tuned.*

In 1899 Stone wrote some letters (5 R. 3630, 3634; off., 1 R. 733), which described some ideas he had regarding wireless telegraphy, and some months later prepared and filed a patent application, on February 8, 1900 (5 R. 3685; off., 2 R. 865), which resulted in Stone patent 714,756. Stone had worked for several years with the American Telephone & Telegraph Company, and was thoroughly familiar with tuned circuits and resonance phenomena (Stone, 1 R. 755, *et seq.*).

The letters described in rough fashion the system and ideas which later were written and illustrated in the elaborate, carefully worded and lengthy description of his application. There is nothing important in the letters, which is not in the later filed application for a patent.

Briefly, the letters refer to tuned circuits, that is, circuits tuned to the same frequency, but these are closed circuits and not tuned antenna circuits. One of the tuned circuits is at the transmitting station, associated with an untuned antenna wire, and the other tuned circuit is at the receiving station, similarly associated with an untuned

receiving antenna wire. The letters clearly state that the two closed circuits should be tuned and that the antenna should not be tuned (Weagant, 2 R. 1649). For example, the Stone letter of July 18, 1889 (5 R. 3637-8) states:

> "In my arrangement the vibratory current developed in the vertical wire is not due to the oscillatory discharge of the wire, but is due to a simple harmonic electro-motive force impressed upon it which electromotive force produces *forced current vibrations* in the wire which forced vibrations as is well known depend for their period and form only upon the period and form of the impressed force *and not upon the electro-magnetic constants of the circuit in which they are developed as is the case with free or natural vibrations of a system*".

The vertical wire is the antenna, and Stone here says that its currents are forced, and do not depend upon "the electro-magnetic constants" of the antenna. If the antenna were tuned, its currents would not be forced, but would depend upon its "electro-magnetic constants". In other words, Stone does not vary the period or tuning of his antenna, but relies upon his closed circuit to provide the tuning.

After writing these letters, Stone then prepared a patent application, which he filed in February 1900, the Court of Claims pointing out that "The Stone application *as filed* impressed these oscillations upon the open circuit, and therefore used 'forced' oscillations in the open circuit of the transmitter" (finding, 1 R. 51). Marconi thereafter filed his application and the Marconi British patent, corresponding to the one here in suit, became public on May 4, 1901 (1 R. 52). Then Stone in April 1902 amended his application to describe tuning the antenna (5 R. 3723), the

amended parts appearing in the Stone patent (p. 2, ll. 16-29 and p. 6, ll. 62-66, 5 R. 3649, 3653; Court of Claims finding, 1 R. 49).

The Stone patent is substantially the same as the application as originally filed, except for the 1902 statements that the antenna might be tuned. Omitting those statements and referring to the patent, it is plain that Stone taught that the antenna should be untuned, *i.e.*, contain forced oscillations, as the Court of Claims said. The patent first says that "present systems of signalling by means of electromagnetic waves" (p. 3, l. 65), have complex waves, while in his "invention the vertical conductor of the transmitting-station is made the source of electromagnetic waves of but a single periodicity" (p. 3, l. 107), and that when the

> "elevated conductor is aperiodic, it is adapted to receive or transmit all frequencies, and accordingly a single aperiodic elevated conductor may be associated with a plurality of local circuits, each attuned to a different frequency after the manner now well known in the art of multiple telegraphy by wire conductors" (p. 3, l. 117, *et seq.*).

The word "aperiodic" means without a natural period, *i.e.*, untuned, so that it will "receive or transmit all frequencies", Stone producing "what are substantially forced electric vibrations in the vertical conductor in lieu of producing natural vibrations in the conductor, as has heretofore been practiced" (p. 4, l. 48, *et seq.*).

The Stone closed circuit which produces the oscillations to be forced upon the antenna is tuned. The receiving station has a similar arrangement, the antenna being untuned and there being an associated tuned closed circuit (p. 5, l. 12).

Nowhere in the application as filed is an antenna circuit referred to as tuned.

The Stone claims refer to an elevated conductor and to "a resonant circuit associated with said conductor", and there is no statement that the elevated conductor is resonant or tuned.

The Stone patent and letters were before the district court in the *Kilbourne & Clark* case, 239 Fed. 338, 339, which sustained the Marconi claims, but are not mentioned in the opinion of the ninth circuit court of appeals, which however states that it has carefully examined the proceedings in the Patent Office, the opinion of the district court, and others, and "In the prior art, as thus disclosed, we find that the claims of the patent may be sustained for the combination of elements such as are found typical in claims Nos. 6, 14, 10 and 20 for both transmitting and receiving apparatus" (265 Fed. 661).

Summary

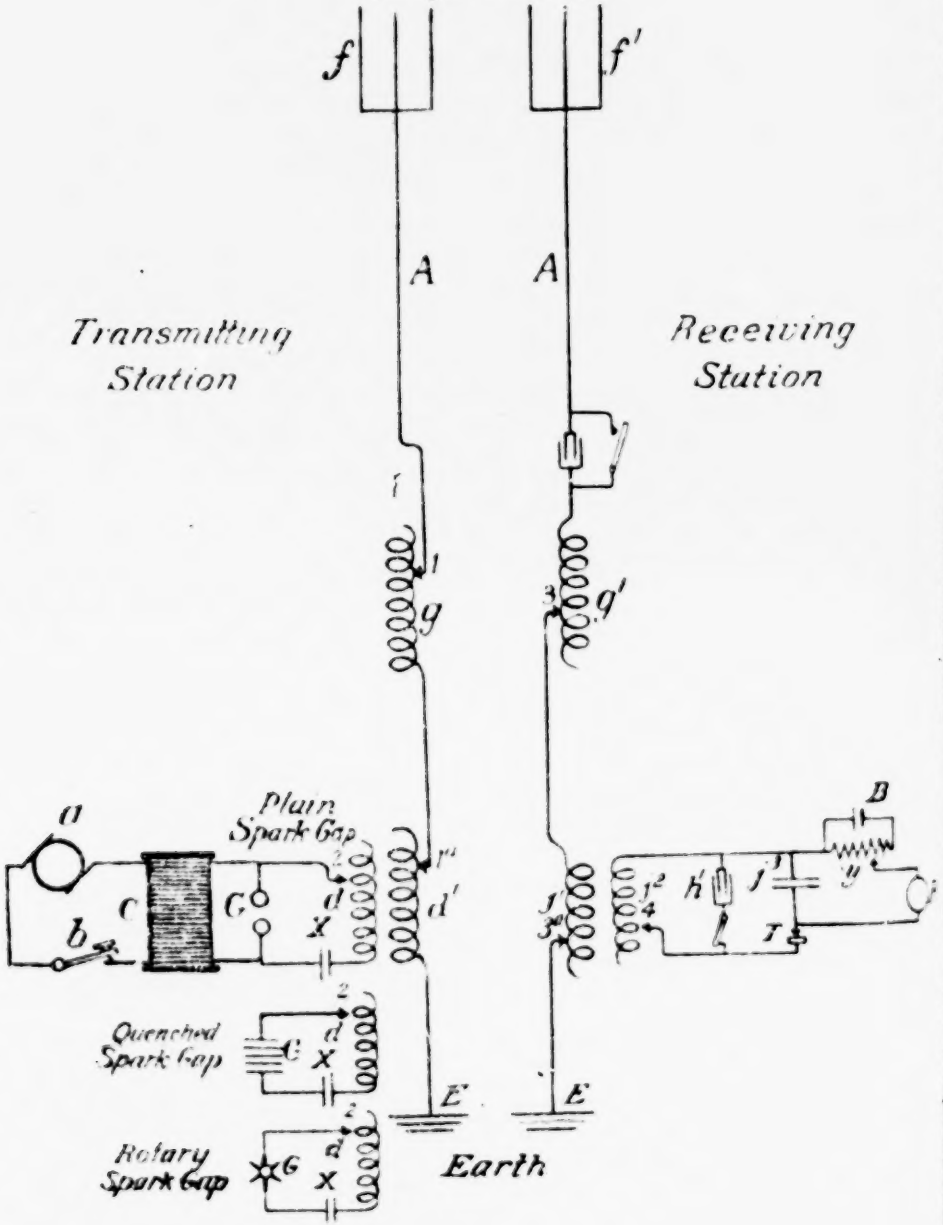
When Marconi in 1900 made his invention, wireless telegraphy was still an unknown land in which the greatest scientists of the times were often at a loss because of their ignorance concerning the fundamental principles, as well as how they could be usefully applied. Edison, Fessenden, Pupin, Lodge, Tesla, and many another were attempting in some way to solve the problem of satisfactory communication without wires.

The record is undisputed that the Marconi invention did solve this problem, changing radio communication from a haphazard, unreliable system covering perhaps 80 miles, to a practical commercial business, operating over many thousands of miles, and the invention going into practically universal, if not universal, use.

PLAINTIFF'S EXHIBIT No. 105

National Electric Signalling System

(Enjoined)



Tesla, Lodge, Stone, and many others came near to Marconi's solution, and it is possible to take parts of some of the things they described and, with some changes, construct from them the Marconi system. But this is not the test of validity, because otherwise no valid patent ever could be obtained for a new and useful combination of old things, regardless of how valuable or unexpected the result would be. And that is not the law, *Keystone Mfg. Co.* v. *Adams*, 151 U. S. 139, 144; *Williams Co.* v. *Shoe Mach. Corp.*, 316 U. S. 364; *Walker, Patents, Deller's Ed.*, 1 Vol. 215, citing cases.

III. The broad claims of the Marconi patent were infringed.

The Court of Claims did not make any ultimate finding of fact as to whether the broad claims of the Marconi patent were infringed, because it considered that they were invalid (1 R. 75). But the opinion and findings show that the Court would have found that these claims were infringed, if the claims were valid, and such finding should have been made.

In the transmitting apparatus charged to infringe, three different kinds of spark gaps were used in the closed circuit coupled to the transmitting antenna, referred to by the Court of Claims as "(a) the plain open-gap apparatus; (b) that having a rotary gap; (c) the larger group using a quenched gap" (opinion, 1 R. 101). These spark gaps are illustrated in plaintiff's exhibit 105 (off., 1 R. 435), reproduced on the opposite page (Waterman, 1 R. 433).

In the closed circuit the high frequency oscillations are created, a spark being produced and extinguished across the

terminals of a gap in the closed circuit, at the frequency of the oscillations, which usually is many hundreds of thousands of cycles a second.

The plain gap had two ball terminals; the rotary had one terminal consisting of rotating studs; and the quenched employed circular plates for the electrodes. Each type of gap had the "property of rapidly cooling and extinguishing the spark," differing in degree (Weagant, 2 R. 1593). The three kinds of gaps operate on the same principle, but the rotary and the quenched would quench the spark quicker than the plain gap, thus enabling the gap to return more quickly to the condition that existed before the spark was created (Weagant, 2 R. 1591).

Many types of spark-gap have been devised before and after Marconi, but they all operated on the same principle with respect to the production of a series of oscillations, each series or group of oscillations lasting while there was a spark discharge across the gap. Whatever type of spark-gap was used, it was essential for high efficiency to get the oscillations in the closed circuit across to the antenna circuit, to be radiated with as little loss of energy as possible. Probably the most important single feature of the Marconi invention was the resonant transfer from the closed to the open circuit, which was both necessary and highly useful, whether the spark gap be of the open, rotary or quenched type (Hogan, 3 R. 1851, 1852).

The type of spark-gap used is immaterial to the question of infringement of the Marconi patent, because its invention relates to tuning transmitter and receiver circuits, and not to spark gaps. The Court correctly found the Marconi patent is not limited "to any specific type of spark producer or oscillation producer" and that the claims in

suit are not limited "to any specific spark producer or to a closed circuit possessing elements which would cause it to function as a persistent oscillator when coupled to the open circuit" (findings, 1 R. 43). It was the opinion of the Court that "All of the wireless sets of defendant made use of apparatus constructed in accordance with the principle which formed the basis of the patent" (opinion, 1 R. 95, 96).

Specifically, with respect to the three types of spark-gap apparatus, the Court of Claims opinion and findings state:

> "We think it clear that the plain open-gap apparatus would be an infringement if the patent was valid, and we are likewise of the opinion that this would be true as to the apparatus using the rotary gap which, as we think, was merely a variation of the plain open gap and apparently used for the purpose of cooling the terminals used in making the gap across which the spark passed" (opinion, 1 R. 101).

The rotary gap was found to have

> "the dual effect of cooling the spark electrode and effecting a lengthening of the spark and its quenching as the moving electrodes recede from the fixed electrode.
>
> "Such operation causes the primary circuit oscillations to tend to cease and the operation, therefore, approximates that of the quenched gap. The circuits and apparatus utilized by the rotary gap apparatus in the Government installation, with the exception of the spark producer or gap, are identical with those used with the plain gap, and the same condition of resonance between the open and closed circuits exists" (findings, 1 R. 44, 45).

With respect to the quenched gap transmitters, the Court of Claims found that they "are substantially similar

in form and function to those utilized in connection with a plain open gap apparatus with the exception that a closer coupling can be achieved between the open and closed circuits" (findings, 1 R. 43), and also said that the quenched gap was

> "only another device for a spark producer and that Marconi in an earlier patent had shown a somewhat similar contrivance. It also appears that when it was used it was necessary to follow the same method of tuning as before. On the other hand, this device apparently was more efficient than the plain open gap for in a comparatively short time it largely displaced the latter system" (opinion, 1 R. 101).

Other courts have also decided that the type of spark gap was immaterial with respect to infringement, all three types of spark gaps having been found to infringe.

In the *National* decision, all three types were held to infringe (Waterman, 1 R. 433; Hogan, 2 R. 1895), and there was "testimony at length regarding the transmitter with the quenched-gap specifically" (Waterman, 3 R. 1975).

The transmitting apparatus held to infringe in *Marconi Co. v. Atlantic Communication and De Forest Co.*, a contested motion for preliminary injunction, was of the quenched gap type (stipulation, 3 R. 2103, *et seq.*; decree off. 3 R. 2094).

In *Marconi v. De Forest Co.*, 225 Fed. 65 (D.C. S.D. N.Y.), aff'd. 2 Cir., 225 Fed. 373, a contested motion for preliminary injunction, quenched gap transmitters were held to infringe (stipulation, 3 R. 2104, 2107; off. 3 R. 2095).

In the *Kilbourne & Clark* case, there were three types of quenched gap transmitters. One type was that manufactured and sold by defendants to the United States

Government and, therefore, the question of its being an infringement was not passed upon by the court (239 F. 355; 265 Fed. 645). The two other types of quenched gap transmitters, the Simpson mercury valve and the Thomson, were held not to infringe, because they did not depend upon tuning, *Kilbourne & Clark* decision, 265 F. 663, 667, as do depend the transmitters in the present case (Court of Claims finding, 1 R. 43). This difference was pointed out in the Interdepartmental Radio Board's preliminary report, in which it was said (4 R. 2818):

> "In the case of *Marconi* v. *Kilbourne & Clark*, a case in which it was argued that there was no effective transfer of energy from the one circuit to the other, the two being substantially energized simultaneously, and in which at any rate *there was no effective transfer from one to the other due to syntony*, was held not to infringe. This, however, is not decisive of the present issue, as to the use of quenched gaps by the Government in which there is a close coupling and a slight or negligible detuning, and *in which, undoubtedly, advantage is taken of syntony to secure an effective transfer of energy*."

The Court of Claims also found that the Government apparatus relied on resonance (syntony, tuning), saying with respect to quenched gap apparatus (finding, 1 R. 43):

> "Defendant instructed its personnel in manuals distributed both by the United States Navy and the Signal Corps of the United States Army, that the closed transmitting circuit should be tuned in resonance with the open circuit in transmitting apparatus using the quenched gap. A Signal Corps pamphlet of 1916, plaintiff's exhibit 92, page 110, states that, '*Tuning of the closed and open circuits to resonance*

and the determination of the correct coupling between them are the two most important adjustments in a quenched spark transmitter."

The Marconi patent was for a broad invention in the then infant art of wireless communication, and there is no reason to limit it to any particular kind of spark gap, when there is no such limitation in the claims and there are not any prior patents or publications which warrant such action.

The Court of Claims declared that defendant's apparatus infringed the claims if valid, and this should have been expressed in a finding.

IV. Claim 16 of the Marconi patent was valid and infringed.

The Court of Claims found that claim 16 of the Marconi patent was valid and infringed (1 R. 117), and that reasonable compensation for the infringing use was $42,984.93, with interest "as part of the entire compensation" (1 R. 156).

Defendant assigns as error the conclusions as to validity and infringement, but does not question the amount of compensation if claim 16 be valid and infringed (specifications of error, *supra*, p. 8).

A. Claim 16 was valid.

In the opinions of other courts on the Marconi patent, there was no discussion of the specific feature of claim 16, which was natural, because the other claims were broader, and they being held valid, there was no reason for consideration of the narrower claim.

Claim 16 is:

> "At a receiving-station employed in a wireless-telegraph system, the combination of an oscillation-transformer, an open circuit connected with one coil of said transformer, said circuit including an oscillation-receiving conductor at one end and capacity at the other end, an adjustable condenser in a shunt connected with the open circuit and around said transformer-coil, a wave-responsive device electrically connected with the other coil of the oscillation-transformer, and means for adjusting the two transformer-circuits in electrical resonance with each other, substantially as described."

The Court of Claims states that the gist of this claim is "an adjustable condenser in a shunt connected with the open circuit" in a receiver, and that prior to Marconi

> "no such apparatus had ever been used or devised. Being new, if it was useful, it was patentable. Its usefulness, we think, is shown by the fact that the receiving apparatus of the Kilbourne & Clark Company and that made by the Telefunken Company used by the Government embodied this device" (opinion, 1 R. 102).

Stone, a witness hostile to plaintiff, testified (1 R. 819) with respect to the British Marconi patent corresponding to the Marconi patent under consideration here, as follows:

> "The British patent No. 7777 of 1900 discloses the really important advances made in the art at that date. Marconi therein discloses a variable inductance coil in series in the antenna, or aerial structure, conductor, and the tuning condenser in shunt with the primary of the transformer in a tuned secondary of which is connected the detector and tuning condensers and inductance coils. Both

> the condenser in the primary and secondary and tuning inductance coils in the secondary, are made variable for the purpose of tuning the circuits with which they are associated."
>
> * * * * * * * *
>
> "The first very clear and complete exhibition of the use of a continuously variable tuning condenser in shunt to the primary of a transformer in a wireless telegraph receiver, so far as I am aware, is contained in the specifications and drawings of the English patent to Marconi, No. 7777, of 1900."

This condenser in shunt (parallel, as distinguished from in series) is in the receiving system (Waterman, 1 R. 358) shown in Fig. 2 of the drawings of the Marconi patent, the patent stating (p. 2, l. 83) "In a shunt around the primary j' I usually place a condenser h," which is said to be similar to condenser e, described as adjustable (p. 1, l. 92). It is a means "of tuning the circuit (Waterman, 1 R. 356). The Court of Claims points out in its finding LX (1 R. 57):

> "The tables on page 4 of the specification thereof [of the Marconi patent] indicate that the purpose of the condenser connected in shunt with the primary winding of the transformer of the receiver, is to enable the electrical periodicity or tuning of the open circuit of the receiver to be altered."

There is nothing in the prior art disclosing this very useful arrangement, and claim 16 is valid.

In this connection, some testimony taken by defendant during the accounting proceedings should be referred to, as apparently defendant is basing a defense of invalidity upon such evidence.

B. The testimony on the accounting was not material to the issues of validity or infringement.

The Court of Claims first heard, considered and adjudicated the issues of validity and infringement of all the claims in suit, including claim 16, it being stipulated that the issues concerning amount of compensation should be deferred until after determination of validity and infringement (1 R. 74, 75). This is common practice in the Court of Claims whose rule 39 specifically authorizes the practice.

The Court decided that claim 16 was valid and infringed by certain Kilbourne & Clark and Telefunken receivers (opinion, 1 R. 102), illustrated in the drawings, exhibits 95 and 79 (finding LXIII, 1 R. 60). This was upon the basis of extensive testimony concerning the receivers (Waterman, 1 R. 369-435; Clark, 2 R. 1488-1511; Weagant, 2 R. 1591-1620; Waterman, 3 R. 1936-1978; Hogan, 3 R. 1878-1912) and in the accounting proceedings, the only receivers that were held liable to account under claim 16 were Kilbourne & Clark, Telefunken and similar receivers.

At no time did defendant move for a rehearing or for leave to offer new evidence concerning claim 16.

During the accounting proceedings, defendant offered in evidence a Pupin patent 640,516 (which had been in the prior record on the issues of validity and infringement, as defendant's exhibit U-2), not as attacking the validity of claim 16, but merely "to show the function of the condenser h in the Marconi patent, and the difference between that function and mode of operation and the function and mode of operation of corresponding condensers in the prior art and in the defendant's device" (defendant's counsel, 3 R. 2376). The Commissioner received it, on the understanding that "it does not in any way attack the validity of claim 16 of the Marconi patent in suit" (3 R. 2377).

On the same basis, defendant also offered a Fessenden patent 706,735 (which also had been in the prior record as a part of plff's. ex. 171), defendant's counsel stating (3 R. 2381): "But here I offer it, not to show invalidity but as showing justification for the defendant's use." There was then some testimony by defendant's witnesses concerning the Pupin and Fessenden patents.

Defendant cannot attack by this testimony the prior decision of the Court of Claims that claim 16 was valid and was infringed by the Kilbourne & Clark and Telefunken receivers. That could only be done by application to the Court to reopen and reconsider its former decision, which was not done. The Court of Claims correctly said:

> "Evidence of the prior art can find no initial entrance into the case through the accounting. The place of prior art in patent law is to invalidate or limit the scope of the patent. The suggestion that it can be introduced for the first time in the accounting for the purpose either of modifying or of interpreting the infringement adjudication is not sound" (opinion, 1 R. 177).

The only possible effect of this testimony might have been to limit the accounting to only the adjudicated types of receivers, but as only those and similar receivers were held liable to account, the testimony was worthless. The Court of Claims in its decision on the accounting proceedings said (1 R. 177, 178):

> "It is clear from the record that the construction and mode of operation of the additional receivers were similar to the Kilbourne & Clark receiver and the Telefunken receiver when the antenna tuning condenser was connected in the parallel position.

> None of the defendant's witnesses has asserted to the contrary, and we have so found in Finding 24."

Claim 16 was decided by the Court of Claims, on a record including the Pupin and Fessenden patents, to be valid and infringed by certain apparatus. Defendant did not attempt to reopen that decision. The accounting was solely to determine how many of the adjudicated types of apparatus had been used, and what was a fair compensation for them. The evidence on the accounting was rightly held by the Court of Claims incompetent as to validity or infringement.

C. The Kilbourne & Clark, Telefunken and similar receivers infringed claim 16.

Findings 23 and 24 (1 R. 139) and the illustrative drawings of the Kilbourne & Clark and Telefunken receivers (1 R. 140) show that the receivers in question employed the shunt condenser and the other features of claim 16, and that the Court rightly found that the claim was infringed by these receivers.

V. The Fleming patent, 803,684, was valid.

The Fleming patent 803,684, application filed April 19, 1905, was granted November 7, 1905. Claims 1 and 37 are in suit. On November 17, 1915, a disclaimer was filed as to low frequency currents, leaving the patent limited to high frequency currents (4 R. 2600).

The Court of Claims decided (1 R. 117) that the claims were not infringed, and said in its opinion that they were invalid because there was unreasonable delay in filing the disclaimer (1 R. 106, 107). The second

circuit court of appeals had previously decided that the claims were valid, that the disclaimer was proper, and that the claims were infringed, *Marconi Co.* v. *De Forest Co.*, 2 Cir., 2 Fed. 560, affirming 236 Fed. 942 (D. C. S. D. N. Y.).

Fleming was the first to discover that a rectifying hot-cathode vacuum tube was useful in wireless communication; that discovery was the genesis of the modern radio art. Practically all modern radio tubes, which are the very heart of radio communication, utilize that discovery.

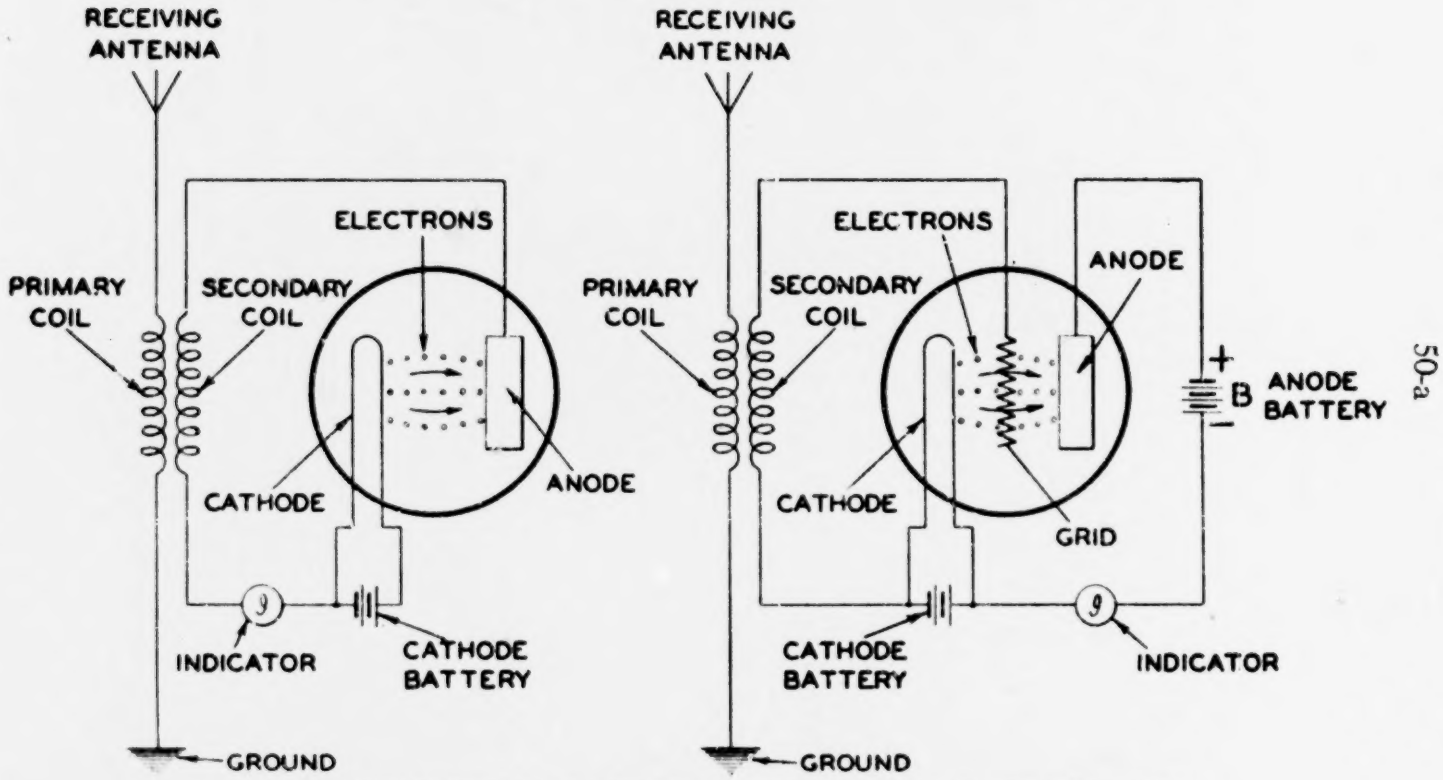
A. Radio tube principles.

This Court has considered radio tubes and their operation in *De Forest Co.* v. *General Electric*, 283 U. S. 664, *Radio Corp.* v. *Radio Laboratories*, 293 U. S. 1, and *Detrola Corp.* v. *Hazeltine Corp.*, 313 U. S. 259. In them some of the basic principles of radio tube operation are stated.

The *De Forest* case involved the amount of vacuum in radio and other tubes, the Langmuir patent in suit there claiming a "high vacuum", and being held to be anticipated by the Fleming patent (283 U. S. 681) and other prior art. The *Radio Laboratories* opinion considered whether Armstrong or De Forest was the first to invent the feed-back or regeneration circuit, used with a three-electrode tube, mentioning that De Forest had added a grid to the Fleming tube, "thereby increasing its capacity as a detector of waves of radio or inaudible frequency and serving better to transform them into waves of audible frequency" (293 U. S. 11).

In the *Detrola* case, this Court discussed the relative merits of a diode and of a triode used as a detector in

DIODE AND TRIODE CHART



SIGNAL VARIATIONS IN RADIO FREQUENCY CURRENTS IN ANTENNA ARE REPRODUCED IN ANODE CIRCUIT, DUE TO A ONE-WAY ELECTRON STREAM IN A VACUUM, FROM THE HEATED CATHODE TO THE ANODE. THE GRID AND ANODE BATTERY AID AMPLIFICATION

modern radio broadcast receiving sets. Diode is another name for the two-electrode tube shown in the Fleming patent, and triode is another name for that tube with the addition of a third electrode, usually called grid, and also sometimes referred to as a De Forest audion, because De Forest contributed the grid. No distinction was made in the *Detrola* opinion between the detecting actions of the diode and the triode, it being pointed out that the diode had the advantage of dispensing with a battery with the corresponding disadvantage of furnishing no amplification, the triode amplifying, but with an additional battery (313 U. S. 263, 264).

There is no difference between the experts as to the essential principles of operation of diodes and triodes (Waterman, 1 R. 436 *et seq.*; Miller, 1 R. 595). Simply stated, their operation is as follows, a chart illustrating them being reproduced on the opposite page.

A diode and a triode each has an evacuated glass bulb, a cathode heated by a current passing through it, an anode, and a circuit outside the tube, connecting the cathode and the anode, called the cathode-anode circuit (sometimes the "plate circuit", because the anode is sometimes called a plate). The triode also has a third electrode inside the tube (called a grid), a cathode-grid circuit and a battery in the cathode-anode circuit.

Both diode and triode depend for operation upon an uni-directional current through the tube, consisting of a stream of electrons emitted by the cathode and proceeding to a cold electrode, which current carries variations derived from the incoming current. The cathode-anode circuit includes a wire outside the tube and also an evacuated space in the tube between the cathode and the anode.

The electrons emitted by the cathode complete the cathode-anode circuit when flowing to the anode, both in

the diode and in the triode. The electrons can flow only in one direction, from the cathode to the anode, and they cannot flow in the opposite direction. Thus the current (electron stream) in the tube is uni-directional (unilateral, one-way), as must be also the entire cathode-anode current, because a part of its circuit, the space inside the tube, is uni-directional.

1. *The process of detection.*

When alternating currents, flowing first in one direction and then in the other, are applied to either a diode or a triode detector, they are rectified, *i.e.* cut in half, because they can flow only one way through the uni-directional circuit. Thus, if a current alternates between one volt plus and one volt minus, when rectified it would vary between either one volt plus and zero, or between one volt minus and zero. This is sometimes called half-wave rectification, because only half the wave of current remains.

The rectified half wave will be repeated in the direct current in the form of variations in its strength (amplitude), in accordance with the form of the impressed currents. These variations are often referred to as pulsations, and also as currents because they are equivalent to alternating currents of the same frequency and amplitude as the pulsations. Technically, they are pulsations, but the art usually refers to them as alternating currents.

When a tube is used in a detector system, the radio frequency currents carrying the signals are rectified, so that the signals appear as audio frequency pulsations in the direct current from cathode to anode, where they can be "detected", by actuating an indicator, such as a galvanometer needle, as in the Fleming patent, or the diaphragm of a loud speaker, as in modern radio broadcast receivers.

The Court of Claims completely misunderstood the nature of detection, and, indeed, the fundamental principles of operation of diodes and triodes, which undoubtedly resulted in its erroneous conclusions concerning infringement. It disregarded all the expert evidence in the case, not only that in behalf of plaintiff, but also that in behalf of defendant, as we shall point out.

The Court of Claims thought that in a diode detector, the diode rectified, and its indicator was operated by *radio* frequency variations, whereas a triode detector did not rectify and its indicator was operated by *audio* frequency variations, there being no *radio* frequency variations in its indicator circuit. The fact is that in both cases there is rectification, both diode and triode have *radio* frequency and *audio* frequency variations in their input and output (indicator) circuits, and their indicators are operated by *audio* frequency impulses.

The Court of Claims said that Fleming's detector made "feeble high-frequency impulses measurable with an ordinary direct-current mirror galvanometer" (finding, 1 R. 63). The "high-frequency" is radio frequency and the "galvanometer" is the indicator. Contrasting the triode and its indicator, a telephone receiver, with the diode, the Court declared:

> "The telephone receiver would not indicate the presence of unidirectional current of constant strength pulsating at *radio* frequencies as would the galvanometer in the Fleming patent" (opinion, 1 R. 71).

The Court also said that Fleming detected

> "by rectification of the full *radio or high*-frequency oscillations impressed upon an indicator adapted to

> register the strength of the rectified one-way pulsating current, while the three-electrode tube in the diagram set out in finding LXXV and marked 'Exhibit 83' detects by substantially suppressing the high-frequency oscillations and amplifying principally the low or audio frequency oscillations" (opinion, 1 R. 111).

But that is not so (Waterman, plaintiff's expert, 1 R. 628; 3 R. 1987; Miller, defendant's expert, 1 R. 606, 607), and it is impossible. The indicator, whether it be a needle, mirror, or the diaphragm of a modern loud speaker, responds only to audio frequency impulses, because these are the signals which are to be reproduced, either by the motions of a needle, seen by the eye, or by air waves, detected by the ear. The radio frequencies, of the order of tens of thousands or millions of cycles per second, are much too rapid for indicators to follow, and even if the indicator could operate at such rates, neither the eye nor ear could observe them. In both the Fleming diode and the De Forest triode, the indicator responds only to audio frequency variations.

And the way that each obtains the audio frequencies is by rectification of the radio frequency currents carrying the audio frequency signals, to produce audio frequency variations, using a one-way directional current which includes the stream of electrons from the cathode.

Defendant's expert witness, Miller, testified with respect to the operation of the Fleming diode detector and the PN (De Forest) triode detector (1 R. 660):

> "In the PN circuit we have two distinct circuits both carrying high frequency currents and low frequency or direct currents. The circuits are distinct and separate because they terminate respectively

> at the grid and plate terminals which are points having different potentials both steady and varying. Radio-frequency voltage variations are applied to the grid, and, as I have explained before, these variations produce through the action of the grid condenser and leak, low or audio-frequency variations of the grid voltage also. Through the controlling action of the grid, amplified variations of both radio and audio-frequency are produced in the plate current of the tube. *The amplified audio-variations affect the indicator I* which is a telephone receiver, the radio variations go to waste in this circuit."

Again, on the same page, he said with respect to "the circuit of Figure 4", which was a triode detector circuit,

> "the incoming oscillations produce, it is true, ***some feeble rectified current pulses***, but only so as to vary the electrostatic potential of the grid electrode. This takes no appreciable power from the received oscillations. There is no indicator for the received oscillations to actuate. The variations in grid potential produce corresponding variations in the plate current which flowing through the indicator produce the response".

With respect to the Fleming diode detector, on the same page, Miller testified:

> "the incoming oscillations are rectified and themselves supply the power to actuate the indicator".

On the basis of the foregoing, Miller says (same page):

> "Thus the detecting action is different in the two devices and the PN circuit, in addition, entails amplification which is a functioning not possessed by the Fleming valve".

Miller is plainly right in saying that the grid enters into the detecting action of the triode. But the point is that the triode, like the diode, uses, and cannot operate without the rectified current through the tube of the applied radio frequency variations, because otherwise the grid circuit would have no audio variations to affect the electron stream and thereby produce audio variations in the current to actuate the indicator.

2. *Amplification, regenerative amplification and oscillation.*

A simple diode cannot amplify, because it merely changes the form of the received currents. A triode can amplify, because of a grid-electron stream amplifying process, with a local battery to provide energy for the cathode-anode circuit. This local battery is additional to the battery for heating the cathode. It may be observed that local batteries were used with the Fleming tube prior to the invention of the triode (Fleming 1905 paper, 4 R. 3140; off., 3 R. 1752) and also with other types of detectors (plff's. ex. 298, 4 R. 3185; off., 3 R. 1800), showing local batteries in Lodge 609,154, Marconi 627,650, etc.). However, these local batteries were not used to amplify.

A very small change of voltage on the grid can produce a larger voltage change in the direct current in the cathode-anode circuit. This is because the grid, through an electrostatic field, acts upon infinitesimally small parts of the current, namely, electrons whose mass is about 1/1700 of hydrogen, the smallest atom. It is as if a river could be diminished at one place to a small rivulet, in which, waves being produced, the whole river would have the same waves.

The grid repeats in the electron stream whatever frequencies are applied to the grid, radio frequencies, audio

frequencies or both (Miller, 1 R. 660). And these same frequencies appear as variations, having the same frequencies, in the direct current which includes the electron stream.

Some tube circuits are used to amplify the radio frequency pulsations (or currents) and others to amplify audio frequency pulsations (or currents). The operation of the tube itself is precisely the same in either case.

From the foregoing, it is plain that when a triode amplifies, it uses the one-way current, including a hot cathode stream of electrons, described in the Fleming patent. The amount of amplification was only about one and one-half times (finding, 1 R. 73), but was increased by the later feedback invention to twenty or thirty times (1 R. 73).

Feed-back, or regeneration, was considered by this Court in *Radio Corp. v. Radio Laboratories*, 293 U. S. 1. Simply, it is amplification repeated many times in the same tube. The incoming currents are amplified by the grid action, appear in amplified form in the output circuit, a part of them is fed back to the input circuit, from where they again go through the tube and are amplified, and so on in a cyclic process, until further amplification ceases due to the resistances in the system (Waterman, 1 R. 446, 497; Miller, 1 R. 646 *et seq.*)

The regenerative amplification above described may be so great that the tube circuits commence to produce their own alternating currents, the tube then being often spoken of as an oscillator tube, because the currents produced are often termed oscillations.

When the tube circuits are oscillating, *i.e.*, producing oscillations, the one-way current through the tube is being employed, as in detection, amplification, and regenerative amplification. . .

3. *A diode can amplify and oscillate without a grid.*

The third electrode inside the tube, usually called a grid, is not necessary for either amplification or for oscillation. Defendant in the present case, as well as the defendant in *Marconi* v. *De Forest*, insisted that a grid was necessary for amplification and for oscillation. Plaintiff in both cases showed that this was not true and that these effects could be produced by gas inside the tube or by an electrical field outside the tube (Weagant, 2 R. 1530 *et seq.*; Waterman, 3 R. 2008-2016, 2019). As plaintiff has never claimed that the Fleming patent describes amplification, oscillations or either such use of gas or external field, or that Fleming knew these things, the joint is not of great materiality. However, it has some importance in showing that the Fleming invention had many potentialities other than its use in a grid tube.

It is plain from the foregoing that the triode, like the diode, depends for its operation upon a hot cathode and a cold anode inside an evacuated vessel, producing a one-way stream of electrons as an integral part of a unidirectional current.

4. *The two-electrode tube, Fleming valve, has been practically used.*

Defendant in the present case, as well as defendant in *Marconi* v. *De Forest*, has contended that a two-electrode tube (diode) has no practical utility. That is not so.

The Court of Claims found that "The Fleming two-electrode valve went into use in a limited way; less than seven hundred Fleming valves having been shipped to various ship and shore stations by plaintiff between 1910

and 1915. These Fleming valves were more sensitive than some types of crystal detectors and less sensitive than other types" (finding, 1 R. 63) and "While in some respects an improvement on the crystal detectors, it did not entirely displace them" (opinion, 1 R. 108).

But the indisputed evidence showed that from 1907 to 1915, which is when the triode with regenerative amplification came in, the Fleming valve was preferred by many wireless operators who had the choice of using other types of detectors, including the crystal, principally because the tube was the most reliable and it was essential to be able to receive continuously weather reports, distress signals, etc. The crystal had the serious disadvantage of having to be readjusted after each message was received and sometimes during reception (Hartley, 2 R. 1403; Reinhard, 2 R. 1424), and the tube was more reliable, although it was more fragile, being made of glass and having a delicate filament. The relative sensitivity of the two was about the same or the tube was somewhat better (wireless operators, 2 R. 1372, 1384, 1387, 1411, 1424).

The Fleming valve detector was employed in many stations, and the names of many American line, British line, German line and privately owned ships, relying on Fleming valves, are listed in the record (2 R. 1360, 1371). A Fleming valve receiver was in continuous communication for about 72 hours with the ships rescuing survivors of the S.S. Titanic disaster in 1912 (Sarnoff, 2 R. 1388).

At least 1,500 valves were manufactured for plaintiff from 1907 to 1915, which was a large number for that early date, and the records which could be found did not show all that had been manufactured (Brennan, 2 R. 1371). The Stanley "Textbook on Wireless Telegraphy" stated that Fleming patented a valve detector in 1904 and "At that

time it was considered so reliable and robust compared to crystal detectors that it was largely adopted on wireless installations by the Marconi Company" (Weagant, 3 R. 1762). About 1915, it was planned to replace all the crystal detectors used by the Marconi Company with the Fleming diode, but this was not done because of "the rapid development of the three-electrode device" (Weagant, 3 R. 1759).

The Fleming diode has been used in modern radio broadcast receivers (Mauborgne, 2 R. 1151), and was considered by this Court in such use, *Detrola Corp.* v. *Hazeltine Corp.*, 313 U. S. 259. The essential rectifier principle of Fleming is still used today, in its original diode form.

Unquestionably, the addition of a modern high vacuum (*De Forest Co.* v. *General Electric*, 283 U. S. 664), a grid, feed-back (*Radio Corp.* v. *Radio Laboratories*, 293 U. S. 1) and many other inventions, have increased greatly the usefulness of the hot cathode type of tube. But all these inventions and improvements have utilized and been based upon the fundamental operation taught and disclosed by Fleming. As this Court said in *Radio Corp.* v. *Radio Laboratories*, 293 U. S. 1, 14, on the point of whether the De Forest feed-back patent was entitled to cover the use of an oscillator as a generator of radio frequencies, despite the possible ignorance of De Forest as to such use:

> "If De Forest's explanations and excuses were to be disregarded altogether, the result at most would be that the apparatus of the coupled circuits had potencies and values more important than the uses that were immediately apparent, potencies and values at least dimly apprehended, and never discarded or forgotten down to the time of their complete fruition

> The benefit of all alike belonged to the inventor. *Corona Cord Tire Co.* v. *Dovan Chemical Corp.*, 276 U. S. 358, 369; *Roberts* v. *Ryer*, 91 U. S. 150, 157; *Stone* v. *Chicago*, 104 U. S. 547, 550; *cf. Lowell Manufacturing Co.* v. *Cary*, 147 U. S. 623, 634; *The Telephone Cases*, 126 U. S. 1, 536; *Robinson, Patents*, Vol. 1, § 81, p. 124."

B. The Fleming patent, and its claims 1 and 37.

The Fleming patent was a pioneer in the radio art, and upon its invention has been founded the marvelous radio industry of today. There was nothing in the wireless art prior to him which taught the invention, set forth in his patent and claims 1 and 37 in suit.

The Fleming patent states (p. 1, l. 11, *et seq.*):

> "This invention relates to certain new and useful devices for converting alternating electric currents, *and especially high-frequency alternating electric currents or electric oscillations*, into continuous electric currents for the purpose of making them detectable by and measurable with ordinary direct current instruments, such as a 'mirror-galvanometer' of the usual type or any ordinary direct-current ammeter".

And (p. 2, l. 102, *et seq.*):

> "It will be understood that when an alternating current is impressed upon a circuit including one of my improved rectifiers, as in Fig. 1, the alternating impulses in one direction will be suppressed and the alternating pulsations in the other direction will pass through the circuit in the form of a pulsating unidirectional current. This pulsating unidirec-

> tional current actuates the galvanometer or other continuous-current-indicating instrument I".

It is this "pulsating unidirectional current", produced by the hot cathode and anode in the tube, whose pulsations actuate the indicator in the output circuit, of either a diode or a triode.

Claim 1 of the Fleming patent, as originally filed, was:

> "The combination of a vacuous vessel, two conductors adjacent to but not touching each other in the vessel, means for heating one of the conductors, and a circuit outside the vessel connecting the two conductors."

On November 17, 1915, this claim was limited to use "in connection with high frequency alternating electric currents or electric oscillations of the order employed in Hertzian wave transmission".

Claim 37 is as follows:

> "At a receiving-station in a system of wireless telegraphy employing electrical oscillations of high frequency a detector comprising a vacuous vessel, two conductors adjacent to but not touching each other in the vessel, means for heating one of the conductors, a circuit outside of the vessel connecting the two conductors, means for detecting a continuous current in the circuit, and means for impressing upon the circuit the received oscillations."

C. The claims were valid.

Radio commenced in 1884 with the discoveries of Hertz and from that time on many eminent scientists worked on devising apparatus which would enable wireless communication, including Marconi, Lodge, Fleming, Fessenden,

Pupin, Edison and many others. But no one proposed the use of a rectifying hot cathode tube until Fleming, who filed a British patent application on November 16, 1904 (finding, 1 R. 63), his United States application for the patent in suit having been filed April 19, 1905.

The closest references are an 1884 Edison patent 307,031 and a 1903 French patent to Vaibrieze 327,687.

Edison patent 307,031.

The Edison patent (4 R. 3295; off., 1 R. 690) describes "a system of incandescent electric lighting" in which there is "a standard lamp" (pat., p. 1, ll. 44, 45), through whose filament passed the ordinary direct current for heating the filament to incandescent. Edison put a plate inside the lamp, which received current, and was connected to a galvanometer needle which would indicate changes in the current, or could "close circuit to electrically-operated devices for accomplishing the automatic regulation of the generator supplying current to the system, or for any other purpose" (pat., p. 1, l. 60 *et seq.*). This idea of thus regulating the voltage of the current supplied to the filament amounted to nothing (Waterman, 3 R. 2027), and taught nothing. Edison was interested in wireless communication, as evidenced by his 1891 patent 465,971 for such a system (1 R. 21), but there is no contention that he ever thought that his lamp had any relevancy to wireless.

In the present case, the Court of Claims refers to the 307,031 Edison patent (finding, 1 R. 64, 65) and declares that "Edison's tube is referred to as the two-electrode tube"; although there is nothing in the record to suggest that it was ever referred to as anything more than the lamp it is, at least until long after Fleming.

Defendant's expert witness testified (Miller, 1 R. 679):

> "At this time [1883] the mechanism underlying Edison's discovery was completely unknown, and the phenomenon was mystifying. It was called the 'Edison effect'. In 1884 Edison obtained a patent on his device, utilizing it as a means of controlling the voltage supply for incandescent lamps."

As has already been pointed out, this "Edison effect" meant nothing to Edison in connection with wireless. And it was as unobvious to others, including many who published papers on it (Waterman, 3 R. 2026). Professor Houston in 1884 gave a paper before the American Institute of Electrical Engineers (5 R. 3459; off., 1 R. 692); Fleming himself, in 1890 had a paper in the Proceedings of the Royal Society, in which for the first time was pointed out the possibility of rectifying alternating current (4 R. 3131; off., 3 R. 1572); in 1897 there was a paper by Howell before the American Institute of Electrical Engineers (5 R. 3459; off., 1 R. 692); a 1904 article was published by Dr. Wehnelt, a great scientist, in the Physikalishe Zeitschrift (4 R. 3515; off., 1 R. 692); and there were many other articles and discussions, but no one knew or suspected that there was any practical usefulness in the "Edison effect", notwithstanding the intensive studies and hundreds of experiments conducted on this phenomenon.

The courts in the *Marconi* v. *De Forest* case were right in their views concerning this Edison defense. The district court said (236 F. 946):

> "Stripped of technical phraseology, what Fleming did was to take the well-known Edison hot and cold electrode incandescent electric lamp and use it

> for a detector of radio signals. No one had disclosed, nor even intimated, the possibility of this use of a device then long known in another art. Cohering filings, magnets, electrolytes, and sensitive crystals *at that time*, failed to give any hint of the utility in this art of the Edison lamp. What led Fleming to his result was his adherence to the theory of the 'rectified' alternating currents."

And the court of appeals (243 Fed. 504):

> "Edison's patent stated a fact and suggested a tantalizing mystery, because even he did not pretend to state or assert that he knew why his 'effect' took place. His disclosure remained (so far as we can discover from this record) a laboratory problem until Fleming applied it (whether with a wrong theory or a right one is immaterial) to a new and very practical field of usefulness."

Valbreuze French patent 328,687.

The Court of Claims correctly found that this 1903 patent (5 R. 3540; off., 1 R. 693) was proposed for use as a rectifier of radio currents and that it had two electrodes in a vacuum tube, neither of which was heated (finding, 1 R. 65). As it lacked the essence of the Fleming invention, which requires a heated cathode to emit electrons, and is a useless device (Weagant, 3 R. 1765; Waterman, 3 R. 2027), the Valbreuze patent argues strongly that the Fleming invention was not obvious.

What Fleming did was invention, as held by the courts in the *Marconi* v. *De Forest* case, relying upon the following and other decisions of this Court.

In *Du Bois* v. *Kirk*, 158 U. S. 58, a Kirk patent for movable dams was upheld, although the structure used was not in itself new, this Court stating (p. 63):

> "It was in fact the application of an old device to meet a novel exigency and to subserve a new purpose."

In *Hobbs* v. *Beach*, 180 U. S. 383, 392, a patent for a machine for attaching strips to the corners of boxes was sustained, though a similar structure had been used previously in addressing machines.

> "Beach did not have before him a machine for attaching strips to the corners of paper boxes, but a machine for attaching addresses to newspapers, and while there is an analogy, there can scarcely be said to be a similarity in these functions."

D. The claims were infringed.

Claims 1 and 37 are infringed by defendant's use of the triodes, both as a matter of substance and as a matter of claim terminology.

Claim 1, as modified by the disclaimer, calls for a vacuous vessel (evacuated glass bulb), heated conductor (cathode), cold conductor (either grid or anode), and a circuit outside the tube, used in connection with high frequency alternating currents. This in terms describes defendant's triodes, whether used in detector, amplifier or oscillator circuits, and, as a matter of substance, they use the gist of the invention, as stated *supra*, pages 52-57.

All of defendant's triode circuits employed, in connection with either the transmission or the reception of high frequency alternating currents, a unidirectional current in a vacuum tube circuit, having a heated cathode to emit electrons which proceed to a cold conductor. It was essential to their operation.

In receiving, the tubes were used in detectors, causing an indicator to respond to the signal variations which are carried by the high frequency alternations, and in amplifiers, causing the received electrical variations to be amplified, in each case utilizing the uni-directional current in the tube circuits.

In transmitting, the tube circuits were used as oscillators, employing regeneration, which also depends upon the uni-directional current in the tube circuits.

The audio frequency amplifiers, using tubes, claimed by plaintiff to infringe the patent, were used as a part of a detector system, in which either a crystal or a tube detector produced audio frequency variations, which were then amplified so that they could be detected by the ear. If the received signal was too faint to be readable, one or two tubes were included in to the detector system, so that the ear could observe the signals (Waterman, 1 R. 448).

Claim 37 is more limited than claim 1, claim 37 calling for, among other things, "a detector comprising a vacuous vessel", etc., and "means for detecting a continuous current in the circuit". So defendant's tubes when used in oscillators, or in amplifiers apart from a detector tube, did not infringe this claim, but did infringe when used in detectors.

1. *The Marconi* v. *De Forest and Radio Audion decisions on detectors, amplifiers and oscillators.*

In the original *Marconi* v. *De Forest* case, one of the principal issues was whether a detector, using a De Forest triode, infringed the Fleming patent, both the district court and the circuit court of appeals so deciding. Subsequently, a motion was made upon affidavits to extend the

injunction to amplifiers and "oscillions" which was the De Forest trade name for oscillators. The motion was granted as to amplifiers, but a trial was ordered as to oscillators and, after the taking of evidence regarding oscillators, it was held that the oscillators infringed claim 1 (4 R. 3246, 3247; off., 2 R. 1340). The Court of Claims disagrees with these decisions, apparently because it thought that there was no substantial issue as to infringement of the Fleming patent in the main *Marconi* v. *De Forest* case, the Court of Claims saying (1 R. 112)

> "both sides represented to the court and agreed that the inherent qualities of the two-electrode tube and the three-electrode tube are the same. This being admitted by counsel, the decision, of course, was based upon that conclusion."

But this agreement was with respect to some De Forest patents, and not the Fleming patent, whose infringement was bitterly contested by defendant, as is very plain from the opinions of the district court, 236 Fed. 951-955, and of the court of appeals, 243 Fed. 564, *et seq.* The Court of Claims was misled by an observation of the court of appeals in the *Marconi* case in considering the question of infringement of certain counterclaim De Forest patents, not in suit here, where it was said (243 F. 565):

> "While not accepting such view of the law, we shall first ascertain what visible objects plaintiff has made, sold, or used *which are said to infringe the counterclaim patents*. The detectors called by defendant 'Marconi's earlier infringement' or the 'two-electrode audion' are especially complained of, though, *since it is agreed that the 'two' and 'three'*

> *electrode audions operate on the same basic principle*, no reason appears why defendant must not contend that the same things which admittedly infringe the confessed patents also infringe the counterclaim patents".

But this had nothing to do with the question of whether the diode and the triode operated on the principle of the Fleming patent, but instead, whether the ideas of certain De Forest patents, the subject of a counterclaim by the De Forest Company, were used in the Marconi tubes. These counterclaim patents were based on the idea of using conductive gas in the tubes, while it was agreed that the so-called audions of plaintiff, whether two-electrode or three-electrode, operated in a vacuum, by a hot cathode stream of electrons, independently of gas, which was the "basic principle" referred to. As for the Fleming patent, the De Forest Company never agreed that its triodes operated on the same principle as the patented Fleming tube.

In *Radio Corp.* v. *Radio Audion Co.*, 278 Fed. 628 (D. C., Dela.), a motion was made for preliminary injunction upon affidavits, the district court deciding that claim 1 of the Fleming patent was valid and infringed by defendant's tube detectors, saying "I am not satisfied by the present record, consisting largely of *ex parte* affidavits, that the defendant's device, when used as an amplifier, or as a generator of high-frequency electrical oscillations, falls within the scope of either of those claims", and also not deciding whether claim 37 was "invalid for want of a supplemental oath". The opinion is very brief, does not state the reasons for the conclusions, and therefore is of little aid on the issues here. There was no appeal, the decision being in January, 1922, the patent

expiring in November, 1922, defendant having practically ceased business, and any possible recovery of damages not being worth the trouble and expense of further litigation (stipulation, 3 R. 2093).

E. The disclaimer was not filed unreasonably late.

The Court of Claims in its opinion said that there was "unreasonable delay in making the disclaimer * * * and that the Fleming patent must be held invalid for that reason" (opinion, 1 R. 106), but did not so find (1 R. 75, 117). There was no unreasonable delay.

The patent issued on November 7, 1905, and the disclaimer was filed November 17, 1915, shortly before the commencement of the trial in *Marconi* v. *De Forest*.

The controlling principles are stated in *Ensten et al.* v. *Simon, Ascher & Co., Inc.*, 282 U. S. 445, 452:

> "'The same principle which forbids a patentee to assert a right to more than he has actually invented compels him to disavow the right as soon as he discovers that it has been unjustly claimed. Unreasonable delay in disclaiming is thus tantamount to an original fraudulent claim, and through it the patentee loses the privilege of making the amendment by which alone his patent could be saved. The question of unreasonable delay is a question for the court, upon the facts as found either by its own investigation or the verdict of a jury. *Delay begins whenever the patentee becomes aware that he has claimed more than he has invented or described.* In cases where the excess is not apparent at once upon the inspection of the patent by the patentee, the allowance of his claim by the patent office raises such a presumption in its favor that he may rely on its

validity until a court of competent jurisdiction decides that it is broader than his real invention.' *Robinson on Patents* (1890), Vol. II, p. 284."

In the present case, the Patent Office allowed claim 1 and there had been no decision with respect to it before the disclaimer was made. The Court of Claims thought there was unreasonable delay because Fleming in 1890, and others subsequently, had observed the so-called Edison effect. The Court of Claims says (opinion, 1 R. 106):

"Fleming stated further in his patent:

'I have discovered that if two conductors are enclosed in a vessel in which a good vacuum is made, one being heated to a high temperature, the space between the hot and cold conductors possesses a unilateral electric conductivity, and negative electricity can pass from the hot conductor to the cold conductor but not in the reverse direction.'

But this was not a new invention. As stated above, Fleming himself some fifteen years before (1890), in a lecture, showed that the current flowed only in one direction when *an alternating current was used* in connection with the lamp of an Edison apparatus, and discussed the flow of current from the hot negative terminal of the lamp to the cold electrode of the plate, observing that negative electricity flowed from the plate into an additional circuit connected with the lamp. In 1897 similar statements made by Howell and Kennelly were published. In stating this feature in his patent specifications as new and patentable, Fleming *must have known* that he was making a claim that could not be sustained. There could have been no inadvertence in making this statement, and this matter alone would seem to be sufficient to render the Fleming patent invalid."

But there is nothing in the record to show that the Fleming patent was not correct in stating that Fleming discovered what is set forth in the above quotation, and which is also in his 1890 paper (deft's ex. K-1, 4 R. 3445; *off.*, 1 R. 692). Fleming was the first to discover this, and there is no basis in the record for a contrary finding or conclusion. The Court is also mistaken in thinking that this claimed discovery was disclaimed, because it was not, as clearly appears from the disclaimer at the end of the patent. The disclaimer only limited the patent to the use of the diode device in connection with radio frequency currents.

As this Court stated in the *Ensten* opinion, "Delay begins whenever the patentee becomes aware that he has claimed more than he has invented or described". Disclaimers filed after suit has been commenced are not necessarily too late, *Smith* v. *Nichols*, 88 U. S. 112, 117; *Sessions* v. *Romadka*, 145 U. S. 29, 41; *Carnegie Steel* v. *Cambria Iron*, 185 U. S. 403, 435; *France Mfg. Co.* v. *Jefferson Electric Co.*, 6 Cir., 106 F. 2d 605, certiorari and rehearing denied, 309 U. S. 657, 696.

In the present case, the gist of the invention was Fleming's discovery that the phenomenon observable in an incandescent lamp with an interior plate added to it could be utilized in radio communication, by constructing a tube with proper circuits and applying to it radio frequency currents carrying signal variations. The only system described in the patent and the only use of the device disclosed in the contemporaneous 1905 Fleming paper (plff's. ex. 269, 4 R. 3140) was with such currents. Fleming was the first to teach that the Edison effect could be employed as a useful rectifier of either high (radio) frequency or low fre-

quency currents; before his 1904 discovery, this Edison effect was merely a laboratory curiosity. Although claim 1, without a disclaimer, probably would have been held valid and infringed in the *Marconi* v. *De Forest* suit, there was no reason for litigating this question, because the only devices complained of were used with radio frequency currents. It was plain common sense to confine plaintiff's claim to the only things in controversy, by the disclaimer, and thereby avoid unnecessary argument.

The second circuit court of appeals in *Marconi* v. *De Forest*, 243 Fed. 560, 565, said:

> "The contention that Fleming's patent, whatever its original merit or lack thereof, was voided by an unlawful disclaimer, is without substance. The mistake (if there was one) was in claiming something not needed, and the disclaimer abandoned what was not wanted, without broadening or enlarging any claim; it also left the claims fully supported by the original specification. No injury to defendant, or any one else, is shown. The procedure is within *Carnegie Steel Co.* v. *Cambria Iron Co.*, 185 U. S. 403, 22 Sup. Ct. 698, 46 L. Ed. 968, and our former decisions in *Simplex, etc. Co.* v. *Pressed Steel Co.*, 189 Fed. 70, 110 C. C. A. 634, and *Strause, etc. Co.* v. *Crane Co.*, 235 Fed. at page 129, 148 C. C. A. 620."

There was no unreasonable delay in entering the disclaimer.

In any event, the plaintiff, which is suing as assignee of the patentee, is entitled to the benefits of the disclaimer statute without being penalized for delay in filing a disclaimer. The disclaimer provisions are contained in Revised Statutes 4917 and 4922 (35 USC, Secs. 65 and 71). Section 4922 provides that a suit may be brought on a

patent, even if it claims more than it should, by a "patentee, his executors, administrators, or assigns"; that "plaintiff" may not recover costs "unless the proper disclaimer has been entered"; and also "But no *patentee* shall be entitled to the benefits of this section if he has unreasonably neglected or delayed to enter a disclaimer." Thus Congress distinguished between penalizing a patentee, whose knowledge might be such as to make unreasonable the delay in filing a disclaimer, and an assignee or purchaser of the patent, which might not have such knowledge, and which, therefore, is nevertheless entitled to the benefits of the section.

Conclusion

The decision of the Court of Claims should be reversed with respect to claims 1, 2, 3, 6, 8, 10-14 and 17-20 of the Marconi patent 763,772, because they are valid over the prior art and those claims should be declared infringed, as in effect found by the Court of Claims if the claims are valid; the decision below that claim 16 of the Marconi patent is valid and infringed should be affirmed; and the decision below that claims 1 and 37 of Fleming patent 803,684 were not infringed should be reversed, and those claims should be declared valid and infringed.

Supreme Court of the United States

OCTOBER TERM, 1942.

Nos. 369 and 373.

MARCONI WIRELESS TELEGRAPH COMPANY OF AMERICA,
Petitioner and Cross-Respondent,

vs.

THE UNITED STATES,
Respondent and Cross-Petitioner.

REPLY BRIEF FOR PETITIONER AND CROSS-RESPONDENT

This reply brief will deal with the issues in both cases, Nos. 369 and 373, namely, the broad claims of the Marconi patent and the Fleming patent, No. 369, and claim 16 of the Marconi patent, No. 373.

I. Marconi 763,772, broad claims.

A. The claims were valid.

The broad claims in suit of Marconi patent 763,772 were held invalid by the Court of Claims.

There is no dispute concerning the teaching of the Marconi patent, which discloses and claims a tuned transmitting antenna circuit, an associated tuned circuit (to

produce radio frequency currents), a tuned receiving antenna circuit, and an associated tuned circuit (to detect radio frequency currents).

Nor is there much serious dispute concerning what the prior art discloses, although here it will be necessary, as will be pointed out, sometimes to distinguish between that disclosure and defendant's inferences therefrom.

Clerk Maxwell in 1865 published a mathematical theory of electro-magnetic waves, usually referred to as the electro-magnetic theory of light, but he did not disclose "the theory of wireless telegraphy", as defendant's brief asserts (p. 30) nor even mention that art.

Hertz, in the period of 1879 to 1890 (5 R. 3872) discovered that it was possible to produce electro-magnetic waves of substantial strength, and defendant's brief (p. 33 *et seq.*) says he understood something about tuning. However, whether he did or not is unimportant because Lodge, earlier than Marconi, clearly understood the then familiar principles of tuning and knew that tuned circuits were sometimes desirable in wireless telegraphy, as defendant states (brief, p. 35), and plaintiff agrees.

The prior Marconi patent 586,193, formerly in this suit, as reissue 11,913 (4 R. 2507), is referred to in defendant's brief (p. 39), but it did not have any tuned circuits, nor does defendant so claim.

The prior art against the Marconi patent relied upon by defendant are Tesla 645,576, Lodge 609,154, Marconi 627,650, and the Stone patent 714,756 and letters. None of these is new here, each having been before one or more courts which sustained the Marconi patent. Before considering this prior art, it may not be amiss to state briefly the test to be applied to it.

Anticipating disclosures must be substantially the same in structure, mode of operation and effect.

This well established principle is recognized in defendant's brief (p. 42), stating

> "the propriety of the conclusion below that the prior art invalidated Marconi's patent depends upon whether the anticipating disclosures and Marconi's device were substantially the same in structure, mode of operation and effect."

To the same effect are decisions of this Court, including *Clough* v. *Barker*, 106 U. S. 166, 176:

> "The structure was not designed for the same purpose as Clough's, no person looking at it or using it would understand that it was to be used in the way Clough's is used, and it is not shown to have been really used and operated in that way."

Topliff v. *Topliff*, 145 U. S. 156, 161:

> "It is not sufficient to constitute an anticipation that the device relied upon might, by modification, be made to accomplish the function performed by the patent in question, if it were not designed by its maker, nor adapted, nor actually used, for the performance of such functions."

We shall turn now to the prior art relied upon by defendant.

1. TESLA PATENT 645,576.

The Tesla patent 645,576 (5 R. 3602) has no relation to the Clerk Maxwell, Hertz, Lodge or Marconi electromagnetic work, nor to ether (Hertzian) waves, which Tesla

considered "practically impossible" for his purpose (Tesla pat., plff's. main brief, pp. 26, 27). Tesla proposed instead to produce a current, and to conduct it over wires and a conducting strata of air, like "a copper wire" (Tesla pat., p. 3, l. 101; 5 R. 3005), to the place where it was to operate motors or lamps. He did not contemplate "the transmission of waves", as defendant's brief asserts (p. 44), but merely currents over conductors.

Tesla did not tune his transmitting wire or his receiving wire, because the wires were part of a power line, as in the ordinary power line system of today. That is the reason why he neither shows a variable inductance coil or other variable element in the wires nor says that they are tunable (they could not be tuned). He did want maximum voltage in his circuits, which he obtained by synchronized circuits (plff's. main brief, p. 29 *et seq.*).

The conclusions of the Patent Office and of the courts in the French, National and Kilbourne & Clark suits (plff's. main brief, pp. 31, 32) that Tesla did not invalidate the Marconi patent were right.

(2) LODGE PATENT 609,154.

Lodge patent 609,154 (4 R. 2579) discloses a tuned antenna, for either a transmitter or a receiver, the tuning being by a variable inductance coil. Lodge also had closed circuits (the antenna is an open circuit) associated with his antennas, but the closed circuits were not tuned (plff's. main brief, p. 33), nor does defendant's brief so assert (p. 46 *et seq.*).

As defendant's brief states (pp. 35, 36), Lodge fully understood the principles of tuning or resonance, which, of course, had long been familiar knowledge among physicists.

but what Lodge did not know was what electrical circuits should be tuned, to accomplish the great advance in the art obtained by the Marconi invention. Electrical systems are like other physical systems, and some parts should be tuned to certain frequencies, other parts to other frequencies and some not to any frequency. The knowledge that tuning is possible is not enough—there is also required the knowledge of whether or not to tune and how much. The fact that Lodge, a brilliant worker in the wireless and other fields, did not understand the importance of tuning the associated circuits argues strongly for invention. "How then can I treat as obvious at the latter date what so able a man as Lodge entirely failed to see at the former date," Justice Parker, *Marconi v. British, etc. Co.*, 4 R. 2546.

3. MARCONI PATENT 627,650.

Marconi patent 627,650 (5 R. 4085) has a receiving system, in which the open (antenna) circuit is tuned, but an associated closed (detector) circuit which is not tuned, as found by the Court of Claims, saying "It was not known to Marconi at the time this patent was filed that it was desirable to have the closed oscillating circuit in tune with the open oscillating circuit" (finding LII, 1 R. 47).

Defendant's brief (p. 55) contends that the closed circuit was tuned, because its witness Loftin said it was, defendant asserting that plaintiff's witness was wrong in saying that it was not. But the Court of Claims found, as above stated, that this circuit was not tuned, agreeing in effect with the Patent Office which considered this Marconi patent before granting the Marconi claims in suit (Marconi application history, 5 R. 3993).

4. STONE PATENT AND LETTERS.

Stone patent 714,756 (5 R. 3648), as originally filed, did not describe tuning the antenna, but only the associated closed circuit. The application was filed on February 8, 1900, the Marconi British patent corresponding to the Marconi patent in suit here was published on May 4, 1901 (1 R. 52), and on and after April 8, 1902 Stone amended his application to describe tuning the antenna (Court of Claims finding, 1 R. 4; Stone application history, 5 R. 3723 *et seq.*).

Defendant's brief says that Stone disclosed a system of four circuit tuning "which the court below held anticipated Marconi", and in which Stone "preferably adjusted the antenna circuit to be resonant to the same frequency" as the closed circuit, defendant's brief (p. 59) quoting three portions from the specification of the Stone patent. But the first two quotations, which describe a preferable antenna tuning (pat., p. 2, ll. 16-20; 5 R. 3649, and p. 6, ll. 62-66, 5 R. 3653) were added in April 1902 or later (Court of Claims finding, 1 R. 51), and the third quotation (pat., p. 4, ll. 17-36; 5 R. 3651) does not mention the antenna, but merely says that the "apparatus" can be tuned to a desired frequency, which was done by the tuning of the closed circuit. "Stone's application as filed was primarily concerned with having the *closed** circuits in tune at both stations", (Court of Claims finding, 1 R. 52, pltf's. main brief, p. 37).

Defendant's brief (p. 63) says that claims 1, 3 and 4 of the Stone application as originally filed claimed "pro-

*Italics ours throughout

ducing the same wave length or frequency in both circuits", *i.e.*, the open antenna circuit and the closed circuit. But that is not so, as apparent upon reading the claims (not quoted in defendant's brief), claim 1, for example, being "The method of developing simple harmonic electromagnetic waves of a definite periodicity, which consists in producing *forced* simple harmonic electric vibrations of the same periodicity in an elevated conductor" (Stone application history, 5 R. 3708), which means producing by force —not by tuning (resonance)—in an antenna the desired currents. Stone knew perfectly the difference between tuned and untuned circuits, and how to describe them. He did not say anywhere in his original application, including the claims, that his antenna was tuned.

Defendant argues that the Stone amendments in 1902 to the effect that the antenna might be tuned must have had a foundation in the original application, because otherwise the Patent Office examiner would have refused them and there is "the presumption that public officers have properly performed their duties" (deft's. brief, p. 64). But the Patent Office has frequently erred in allowing amendments to applications, *Schriber Co. v. Cleveland Trust*, 305 U. S. 47, 56, 57 and cases cited; and defendant relies too strongly upon the presumption that the patent office examiners "properly performed their duties", in view of defendant's attacks upon the grant of the Marconi patent over the prior art urged now by defendant (deft's. brief, pp. 73, 76).

The amendment of the Stone application to add the new feature of antenna tuning was much like the amendment of a Fessenden application "to include the tuning of the closed circuit". *National El. Co. v. Telefunken Wire-*

less, 209 Fed. (D. C., S. D., N. Y.) 856, 864, per Judge Learned Hand, who, incidentally points out (p. 864):

> "in patent causes we are chary of too ready an assumption of the obvious. Everyone concedes that Stone is a very expert person and one of the best men in the art, yet it was not so obvious but that he put an untuned condenser across a coherer in a local circuit".

This was the same Stone, and the entire opinion, filed in 1913, shows how little was known even then concerning the mysteries of wireless.

Turning back to the present case, the Stone letters in evidence (5 R. 3030, 3034), which were written before he applied for a patent on his system, do not contain anything material which he did not put in his patent application, as might be reasonably expected. Stone wanted a single frequency, and he proposed to accomplish this by tuning a single circuit and impressing its currents upon an untuned antenna (plff's. main brief, pp. 35, 36).

Defendant's brief (pp. 71, 72) states that the Stone Telegraph & Telephone Company, organized in December 1901, built and operated some wireless stations and apparatus having tuned open and closed circuits. But all these were in 1902 or later (Stone, 1 R. 762, 772) and, of course, all after Marconi filed his patent application in November 1900, and after the Marconi British patent had been published in May 1901.

Defendant asserts (brief, p. 73 *et seq.*) that "Marconi's 'variable inductance' in the antenna circuit cannot save his patent" which infers, erroneously, that plaintiff so contends. But the Marconi invention was not the use of a variable inductance, nor indeed any other specific way of

tuning an antenna—before Marconi it was known that electrical circuits could be tuned or not tuned, by inductance coils or condensers. His broad invention was the combination of a tuned antenna circuit and a tuned closed circuit. Some of the claims in suit are limited to a variable inductance but others are not.

Claims 1, 2, 3, 8, 12, 13, 18 and 19 specify "a variable inductance"; claim 11 "an inductance"; claims 6, 14, 16, 17 and 20 call for "means" for tuning; and claim 10 for resonant circuits. It is very plain that Marconi, and the Patent Office, did not think that the Marconi invention consisted in only tuning by a variable inductance.

Defendant's brief (p. 78 *et seq.*) comments upon the prior decisions sustaining the Marconi patent: *Marconi* v. *British Radio etc. Co.*, 27 T. L. R. 274, 28 R. P. C. 18, 4 R. 2525; *Marconi* v. *National*, 213 Fed. 815; and *Marconi* v. *Kilbourne & Clark*, 239 Fed. 328, affirmed 265 Fed. 644; but omits mention of the French decision, 4 R. 2622. We think these carefully considered decisions in bitterly contested litigations, in the early days of wireless, when contributions to the practical art perhaps could be more readily appraised at their just value than after the art has fully developed, and paths once discovered seem obvious, speak for themselves.

Marconi made a real invention, he changed wireless operations from experimental signalling for a few miles to regular commercial operation over more than 6,000 miles (Marconi, 1 R. 532; *Marconi* v. *National*, 213 Fed. 848); it was recognized by all the courts considering it as a great practical contribution (plff's. main brief, p. 22); it was used almost exclusively during the period covered by the accounting; and his patent was valid.

B. The Marconi claims were infringed.

Defendant's brief (p. 84 *et seq.*) considers the question of infringement by its transmitters and receivers.

1. DEFENDANT'S TRANSMITTERS.

Defendant's transmitters were of the plain gap type, rotary gap type and quenched gap type, as stated in plaintiff's main brief (pp. 39-44), where it is pointed out that the Court of Claims considered that they all infringed the Marconi claims and would have so found if it had upheld the claims, and the reasons for this conclusion are stated, including defendant's admissions to such effect. Defendant's answering brief does not question any of these statements.

Defendant says that the prior decisions show that its transmitters do not infringe (brief, pp. 79, 80, 87), which it is impossible for us to understand, because the British decision found that a plain gap transmitter infringed (4 R. 2525); in the *National* case the plain gap, the rotary gap and the quenched gap were all found to infringe (plff's. main brief, pp. 28-a, 42), notwithstanding which defendant's brief (p. 79) asserts that in this suit "The apparatus alleged to infringe consisted of a plain gap"; and, in the *Kilbourne & Clark* case, defendant's transmitters were not adjudicated, being expressly excluded from the case, and later found by the Interdepartmental Radio Board to be different from the adjudicated infringements in the *Kilbourne & Clark* case, the Board saying that in defendant's quenched gap transmitters "undoubtedly, advantage is taken of syntony [tuning] to secure an effective transfer of energy" (plff's. main brief, p. 43).

Infringement depends upon whether the circuits are tuned—not upon the kind of gap used. The invention, as expressed in the claims, relates to tuned circuits and not to spark gaps. The Court of Claims correctly found that the claims "in no way limit the patent monopoly expressed in them to any specific spark producer" (1 R. 43).

Defendant's brief asserts that its spark gap circuits were not in "tune with the antenna circuit" (p. 90), there was "non-resonance" (p. 91), "detuning" (pp. 94, 95), "intentionally detuned" (p. 97). But the Court of Claims found as a fact that defendant's plain gap circuits were "in tune or electrical resonance with each other" (1 R. 42); in the quenched gap transmitter there was "tuning of the closed and open circuits to resonance (1 R. 43); and in the rotary gap transmitters "the same condition of resonance between the open and closed circuits exists", as in the plain gap (1 R. 45), the opinion being to the same effect (1 R. 101). These findings were supported by the evidence, as stated in plaintiff's main brief (pp. 40-44).

2. Defendant's receivers.

Defendant's receivers also infringe the claims if they are valid. The Court of Claims in its findings (1 R. 41-45) refers to typical receivers having tuned antennas and tuned closed circuits associated with a detector ("wave responsive device"), and defendant's brief (p. 101 *et seq.*) does not seriously question infringement if the claims were valid over the prior patents to Marconi 627,650 and "Tesla, Stone and others" (deft's brief, p. 102, footnote).

The broad claims in suit of the Marconi patent, 763,772, claims 1, 2, 3, 6, 8, 10 through 14, 17 through 20, were

valid and the Court of Claims erred in deciding otherwise, and the claims were infringed by defendant's apparatus as stated by that court.

II. Claim 16 of the Marconi patent.

The Court of Claims sustained claim 16 of the Marconi patent as valid and infringed, defendant successfully petitioned this Court for a writ of certiorari and the matter is before this Court in case No. 373.

Defendant's brief (pp. 6-8) in this case contends that the Court of Claims erred in deciding that claim 16 of Marconi patent No. 763,772 was valid and infringed, and in deciding that the value of the invention to the defendant should be based on its usefulness in defendant's apparatus.

There were two trials before the Court of Claims. The first, by stipulation of the parties (1 R. 74-75) under a Rule of that Court, was for the purpose of *determining* the issues of validity and infringement of the various patents in suit. The second was for the purpose of ascertaining reasonable compensation for infringement. This is common practice in patent and other cases involving accountings.

On the first trial, the parties thoroughly litigated the issues of validity and infringement of the various claims in suit of the four patents upon which the action was brought. The evidence was submitted to a Commissioner who made his report, and the case was argued before the Court of Claims, which decided that some claims only were valid and infringed, and ordered an accounting as to them. The decision was not satisfactory to plaintiff with respect to broad claims of the Marconi patent and the Fleming patent, nor to defendant as to claim 16 of the Marconi

patent. But neither party moved for rehearing, reargument, nor, at any time, to reopen the decision on validity and infringement.

A. The Court of Claims correctly found that claim 16 was valid and infringed.

Defendant had full notice on the trial of the issues of validity and infringement that plaintiff was relying on claim 16, and both plaintiff and defendant offered evidence regarding its validity and infringement. Defendant had its day (*i.e.*, years) in court.

In plaintiff's opening case, the operation of claim 16 was explained, the claim being quoted (Waterman, 1 R. 356-7, 361, 365), and it was also testified that various receivers of defendant used the condenser of the claim, for tuning the antenna circuit (Waterman, 1 R. 389, 390, 447). Thereafter, defendant put in its case, Loftin, its expert witness, testifying at length concerning the claims in suit, including claim 16, of the Marconi patent with respect to their meaning, validity, and infringement (2 R. 873-1060; infringement of the claims, 985-1060), but without contradicting any of the aforesaid cited testimony on behalf of the plaintiff.

The report of the Commissioner was that claim 16 was valid and infringed, to which defendant excepted, and defendant argued those two issues, and others, before the Court of Claims. Defendant does not contend that these issues were not argued by it before that court (they were, deft's. brief there, validity, pp. 4126 *et seq.*, infringement, pp. 4135 *et seq.*).

The Pupin and Fessenden patents, upon which defendant now argues invalidity and noninfringement (deft's.

brief, pp. 20-31), were before the court on the first trial. Defendant apparently did not then consider them to be so important as it does now, because it did not urge that they showed either noninfringement or invalidity of claim 16 (or any other claim).

The court found (1 R. 57) that claim 16 was "directed to a combination of elements which is new and useful" and that some tables in the Marconi patent "indicate that the purpose of the condenser connected in shunt with the primary winding of the transformer of the receiver, is to enable the electrical periodicity or tuning of the open circuit of the receiver to be altered", and that certain specified receivers of defendant "each has apparatus coming within the terminology of claim 16" (1 R. 60); and as a conclusion of law, that claim 16 was valid and infringed by the specified receivers "and any other apparatus used by defendant coming within its terminology" (1 R. 75).

This decision that claim 16 was valid and infringed, including the finding that in the Marconi patent the shunt condenser tuned the antenna circuit, was based upon undisputed evidence to such effect. Defendant points to no evidence on the first trial to the contrary.

B. In view of the stipulation, as well as under orderly trial procedure, the Court of Claims rightly decided that defendant was precluded from relying on evidence, taken after the interlocutory decision, to show invalidity or noninfringement.

In view of the stipulation, as well as under usual procedure, the issues of validity and infringement of claim 16 were determined by the interlocutory decision of the

court below. Defendant made no motion for new trial (*i.e.*, "to question the correctness or sufficiency of the court's conclusions on its findings of fact or to amend the same", Court of Claims Rule 91) nor otherwise sought to reopen the case on those issues. It accepted the interlocutory decision as final, subject only to review by this Court on the evidence that was then before the Court of Claims.

On proceedings under the interlocutory decision, evidence was taken before a Commissioner to determine the amount of compensation due plaintiff. No evidence was offered by defendant for the purpose of showing that the prior decision on validity or infringement was erroneous (undoubtedly the Commissioner would have rejected any such). Certain testimony regarding the Pupin and Fessenden patents was offered and received, on the expressed understanding that it did not relate to validity (3 R. 2376, 2377, 2381). On the accounting, there was and could be no issue as to validity, and no issue as to infringement by what had been adjudicated to infringe claim 16.

However, on the hearing before the Court of Claims on the question of the amount of damages defendant attempted to raise and reargue the issue of infringement, the Court declined to reconsider the issue (1 R. 175). The question is not whether the Court of Claims had the power to change its former decision (as defendant's brief, pp. 38-39, seems to argue). Of course, a court clearly has the power on a subsequent proceeding to reopen its prior decision, and then decide differently. *Messinger* v. *Anderson*, 225 U. S. 436, 444; *Simmons Co.* v. *Grier Co.*, 258 U. S. 82. But that is not the situation here, because not only did the Court not exercise such power but defendant did

not even so request, as the Court of Claims pointed out (1 R. 175, 177).

C. Even if the accounting evidence be considered, it does not establish non-infringement or invalidity.

Defendant now contends, based on some evidence taken on the accounting, that the shunt condenser of Marconi claim 16 does not tune the antenna circuit, being used merely to loosen the coupling between the antenna circuit and the closed circuit (brief, pp. 17-21). Upon this assumption, defendant argues that the claim is not infringed, because defendant's receivers do use the condenser to tune the antenna circuit (as plaintiff established, Waterman, 1 R. 389 *et seq.*), defendant also saying that the damages awarded by the court were wrong because they were based on the tuning utility of the condenser in defendant's apparatus, and not on the coupling advantage alleged to be shown in the Marconi patent.

Thus, the underlying question is whether in Fig. 2 of the Marconi patent the condenser h tunes the antenna circuit. Defendant now asserts that it does not, relying upon some accounting evidence. Plaintiff asserts that it does, relying upon the undisputed evidence on the trial of the issues of validity and infringement, and also pointing out that the accounting evidence, if competent, does not contradict, but on the contrary, supports this conclusion.

At the first trial, in plaintiff's opening case, it was testified that the condenser tuned the antenna circuit (Waterman, 1 R. 357). In defendant's lengthy answering testimony on the Marconi patent, including claim 16 and other claims, their validity and infringement by defend-

ant's apparatus (Loftin, 2 R. 837-1060), not only was there no contradiction of this, but defendant's expert witness Loftin expressly stated that the Marconi receiving antenna was tunable by the shunt condenser h, not only by inductance (2 R. 876), saying in connection with claim 16 that its shunt condenser "is merely one of numerous ways for obtaining an adjustment of the product of capacity and inductance of a circuit, *in this case the adjustment being obtainable through varying the capacity*" (1 R. 920); and that the condenser was "an arrangement rarely used in tuning the antenna or open circuit through varying the effect of the coil of the winding which it shunts" (2 R. 977). Neither Loftin nor any other witness for defendant questioned the prior evidence in the record that this condenser was used in defendant's apparatus as had been previously shown in plaintiff's prima facie case.

Upon this evidence, the Court of Claims found that claim 16 was valid and infringed, and also that the condenser tuned the antenna (open) circuit, saying that the condenser was "to enable the electrical periodicity or tuning of the open circuit of the receiver to be altered" (*supra*, p. 14).

Turning now to the evidence on the accounting, where defendant's witnesses sought to minimize, but did not deny, the tuning effect of the condenser.

Referring to the condenser in the Marconi patent, defendant's witness Dow testified on the accounting:

> "XQ.557. What is it in the antenna circuit that is *tuned* to the received wavelength?
>
> "A. The antenna f, the coil g', the *condenser h*, and the earth capacity e" (3 R. 2400).

"XQ. 506. Now, if the *condenser h*, in figure 2 of the patent, is variable, then is it not correct to say that a variation of the capacity of that condenser enables the electrical periodicity of tuning of the open circuit of the receiver to be altered?

"A. That is correct" (3 R. 2402).

"A. That the antenna has some effect on the resonance frequency; but that it is principally determined by the value of the *condenser h* and the coil j'" (3 R. 2404).

Wheeler, another witness for defendant, said that the condenser h could be used to bring the receiver into tune with the transmitter (3 R. 2460, 2461, XQs. 212-4, 219), and, "The value of adjustment for condenser h is to adjust it to the exact value of the received wave-length, which may not be exactly .0040" (3 R. 2463, XQ. 239).

Pickard, a witness for plaintiff, also testified in the accounting proceedings to the same effect, pointing out the various tuning advantages of the condenser in the Marconi patent (3 R. 2330-2337).

And it is plain that a variable condenser, such as h, must vary the capacity of the circuit in which it is connected, because that capacity includes the capacity of the condenser.

With respect to the validity of claim 16, defendant contends (p. 24 *et seq.*) that if its receivers infringe, the claim is invalid because of prior art. But this was an issue pertaining to validity and infringement which was litigated in the trial to determine validity and infringement (and was then raised by defendant, "All of the claims read quite as easily upon the prior art receivers * * * as they do upon the defendant's receivers", deft.'s Court of Claims brief, p. 4135). However, the argument then was based upon prior

art patents other than Pupin 640,516 and Fessenden 706,735.

Defendant seeks at several places (by references to testimony on the first trial, by stating that the basic evidence was introduced at the first hearing, brief p. 32, etc.) to make it appear that the accounting evidence is not necessary to its present position. But none of the evidence on the first trial supports or was even intended to support defendant's present argument. Likewise, defendant misrepresents the stipulation, saying (brief, pp. 33-34) that "The parties had stipulated that the first hearing be limited to the issues of validity and infringement", whereas the stipulation was expressly that the issue of reasonable compensation be postponed until the *determination* of the issues of validity and infringement (1 R. 74-75).

If defendant had moved to reopen the case with respect to validity and infringement, to offer additional evidence concerning the Pupin and Fessenden patents, and the motion had been granted, with leave to plaintiff also to offer evidence on these issues, plaintiff would have pointed out, among other things, that claim 16 of Marconi is for a wireless receiving system containing an antenna circuit tuned by a variable shunt condenser, and a tuned transformer-coupled closed circuit with a detector; that the Pupin patent describes a wire telegraph system having no antenna or open circuit or equivalent, and no elevated wire or antenna-earth capacity, and has condensers which are not varied in operation to receive different wave lengths, as in Marconi; that the application for the Fessenden patent (only the application was prior to Marconi) discloses a wireless receiving antenna circuit containing a shunt condenser not used for tuning, and no coupled circuit; and other matters per-

tinent to the issues of validity and infringement. However, as these issues were not open on the accounting proceeding, plaintiff properly made no real effort to meet the evidence upon which defendant now relies to show invalidity and noninfringement.

The Pupin and Fessenden patents were much relied upon as defenses in the *National* case, the opinion there discussing them, particularly Fessenden, 213 Fed. 850 *et seq.*, 860, and holding claim 16 and other claims valid and infringed. Moreover, Fessenden, like Stone, had no thought of tuning until after he had become acquainted with Marconi's invention, after which he amended his application to describe tuning (*United Wireless Co.* v. *National Elec. Sig. Co.*, 198 Fed. 386; *National Elec. Sig. Co.* v. *Telefunken*, 209 Fed. 856; aff'd 221 Fed. 629). In the present case, claim 16 was correctly held valid and infringed, as pointed out in plaintiff's main brief (p. 47).

To conclude, defendant had its day in court and a fair trial on the issues of validity and infringement, the decision of the Court of Claims on claim 16 was supported by the uncontradicted evidence, that decision became the law of the case and binding upon defendant so far as that court was concerned in the absence of a motion to set it aside, and the court rightly refused to consider accounting evidence on the issues of validity and infringement. And, as the Marconi patent had the tuning advantages of the shunt condenser, admittedly in defendant's receivers, the court rightly took such advantages into consideration in ascertaining the damages.

The decision below as to claim 16 of the Marconi patent should be affirmed. In any event, it should not be re-

versed without giving plaintiff an opportunity to meet the evidence which defendant took on the accounting, ostensibly on questions of amount of damages, if such evidence is to be used on the issues of validity and infringement.

III. Fleming patent 803,684.

The Fleming patent is in Case No. 369, upon plaintiff's petition. The Court of Claims found that the claims in suit of the Fleming patent 803,684, claims 1 and 37, were not infringed (findings, 1 R. 72, 117), and said that the claims were invalid because of delay in filing a disclaimer (opinion, 1 R. 106, 107). Defendant's position is that the court below was right on these points, and also that the Fleming patent was invalid because of the prior art and because the subject matter of the disclaimer was improper (deft's. brief, p. 102 *et seq.*).

A. The claims were valid.

Defendant relies for its defense of invalidity upon Edison patent 307,031, some laboratory experiments of Fleming, followed by others, with incandescent lamps, some Wehnelt experiments with oxide coated cathodes in tubes, and a Valbreuze French patent.

1. Edison patent 307,031.

Edison patent 307,031 (4 R. 3295) issued October 21, 1884. It discloses an ordinary incandescent lamp, having a filament heated to glowing incandescence by a direct current, with the addition of a plate inside the lamp. Edison observed that there was a direct current in the external circuit connecting the filament to the plate, and

that the amount of the current was in proportion to the degree of incandescence of the filament. He proposed to use the filament-plate current to indicate or regulate variations in the lighting current in the system, by means of a galvanometer.

Defendant's brief repeatedly refers to this lamp as "the Edison tube" (brief, pp. 7, 113, 116, 117, 118, etc., etc.) presumably to make it seem like a radio tube, but it was nothing but an incandescent lamp with an external circuit to indicate variations in the lighting current, which was never used (Waterman, 1 R. 21), and never meant anything to anyone in connection with wireless, including Edison, who was a worker in many electrical fields, including wireless (Edison 1891 wireless patent, 465,971, 1 R. 21).

Defendant also refers to this lamp as "Edison's two-electrode rectifier" (brief, p. 103), although it was merely a variety of lamp with a circuit for indicating variations in the lighting current, his patent containing nothing with respect to rectification (the change of alternating currents to a direct current), and not even mentioning alternating currents.

The Edison patent does not explain why there was a current in the external circuit, there is no evidence that Edison himself knew why there was, and defendant's expert (Miller, 1 R. 679) admitted that at the time of the Edison patent "the mechanism underlying Edison's discovery was completely unknown and the phenomenon was mystifying".

About twenty years elapsed before Fleming discovered that a hot cathode-cold anode tube had any usefulness in wireless or in connection with electro-magnetic waves, notwithstanding the many eminent scientists who studied and

wrote papers on the mysterious "Edison effect" (deft's. exhibits I-1, J-1, K-1; 4 R. 3413-3448 and L-1, M-1, N-1; 5 R. 3449-3514, including discussions by many scientists).

Defendant's brief (p. 112) asserts that "Structurally, the Fleming tube and its circuit as defined in the claims in suit are identical with those disclosed by Edison", that "Fleming's claim 1 is patterned after the cited Edison claim 5", and that "plaintiff does not seriously dispute that features of the Fleming patent cannot be treated as his discovery". Plaintiff does so dispute seriously, and the obvious differences between the Edison lamp patent and the Fleming patent are apparent from Edison claim 5 and Fleming claims 1 and 37, especially when read in the light of the specifications, as claims should be read. The same rules of interpretation apply to patents, written contracts between the patentee and the government, as apply to other contracts, which are to be read as a whole.

Claims are read in the light of the patent description.

"The claims of a patent are always to be read or interpreted in the light of its specification", *Schriber Co.* v. *Cleveland Trust Co.*, 311 U. S. 211, 217; *Carnegie Steel* v. *Cambria Iron*, 185 U. S. 403, 432; *Fruit Growers* v. *Brogdex*, 283 U. S. 1, 6; *Tilghman* v. *Proctor*, 102 U. S. 707, 730. In *Consolidated Roller Mill* v. *Walker*, 138 U. S. 124, 132, the following statement was approved, viz.: "To understand the nature of the invention intended to be covered by the first claim, resort must be had to the specification".

Turning now to the claims, Edison claim 5 is:

> "5. The combination, with *an incandescent electric lamp* of a circuit having one terminal in the vacuous space within the globe of said *lamp*, and the

other connected with one side of the *lamp-circuit*, and electrically controlled or operated apparatus in said circuit, *substantially as set forth*".

What this means is "set forth" in the specification of the patent, from which it appears that Edison had the ordinary "incandescent lamp", whose filament was heated by a direct current, and a circuit between the filament and a plate inside the lamp, to indicate variations of current in the lamp circuit.

The Fleming claim 1 as originally filed and claim 37 are:

> "1. The combination of a vacuous vessel, two conductors adjacent to but not touching each other in the vessel, means for heating one of the conductors, *and a circuit outside the vessel connecting the two conductors.*"

> "37. At a receiving-station in a system of *wireless telegraphy* employing electrical oscillations of high frequency a *detector* comprising a vacuous vessel, two conductors adjacent to but not touching each other in the vessel, means for heating one of the conductors, *a circuit outside of the vessel connecting the two conductors*, means for detecting a continuous current in the circuit, and means for impressing upon the circuit the received oscillations."

It is plain that the Edison and Fleming claims are substantially different, that the Fleming claims are based upon the disclosure of his patent, including the use of "conductors", explained in the patent as employed for conducting a unidirectional current between them, obtained from alternating currents impressed upon an external circuit containing them, and that they do not cover the Edison lamp.

2. FLEMING'S EXPERIMENTS WITH INCANDESCENT LAMPS.

Fleming experimented with the Edison lamp and observed that if the filament was heated to incandescence by an alternating current, instead of the direct current used by Edison, there would be current in the external circuit in only one direction, *i.e.*, from the heated filament (Fleming 1890 paper, 5 R. 3416, 3511); and later others verified Fleming's discovery (Howell 1897 paper, 5 R. 3459, and see plff's. main brief, p. 64).

In none of these experiments was there any application to the tube of alternating currents from a circuit other than a tube circuit, and, of course, no application of signal carrying currents to be detected.

3. THE WEHNELT EXPERIMENTS.

In October 1904, the Physikalische Zeitschrift, a German scientific paper, was published, containing an article by Wehnelt (translation, 5 R. 3515), on some experiments on certain special types of tubes which contained cathodes having oxid coatings.

In the experiment of Fig. 1 (deft's. brief, p. 119), a direct current battery B is connected between the cathode and the anode, first in one direction and then in another, Wehnelt observing that "The experiment shows consequently that only negative ions are emitted from the incandescing oxid" (5 R. 3516).

In the experiment of Fig. 4 (deft's. brief, p. 120), an anode is pushed "close to the glowing metallic oxid" cathode, the "discharge potential" is about 20 volts when the cathode and anode are connected one way, and in the other way "some thousands of volts, since under deep pressures the cathode drop on metals takes on exceedingly high

values". Discharge potential does not mean current, because current is potential (voltage, electrical pressure) divided by resistance, and Wehnelt does not give the resistance. Wehnelt concludes that "If, therefore, we connect the electrodes A and K with an alternating source of current, *the potential of which lies below the value which the cathode drop on the metallic cathode A has*", the tube "can consequently serve for the purpose of transforming alternating current into pulsating direct currents" (5 R. 3517).

At most, the Wehnelt laboratory experiments showed that, under certain special conditions, an oxide coated cathode might be used in a tube to rectify alternating currents applied to the tube. There was no suggestion that these observations could be applied to and developed into anything useful in wireless telegraphy.

4. VALBREUZE FRENCH PATENT *328,687*.

The Valbreuze French patent *328,687* (translated, 5 R. 3547) is much relied upon by defendant (brief, p. 123 *et seq.*), which repeatedly refers to the tube of the patent as "a two-electrode tube" (brief, pp. 123 *et seq.*), thus confusing it with what the radio art commonly refers to as such a tube, namely, the hot cathode-cold anode type of the Fleming patent.

The Valbreuze patent proposes to use as a detector of high frequency currents a tube which does *not* have a heated electrode, but instead is to rectify by "a point and ball very close together" (Valbreuze patent translation, 5 R. 3550), what defendant's expert called "the well-known sphere and point rectifier" (Miller, 1 R. 682).

Defendant contends that Valbreuze has an electrode heated to emit electrons, like the Fleming patent (brief, p.

126, 128, 165, etc.), declaring that the point would be heated, by ionic bombardment, etc., so that it would emit enough electrons to operate. The record does not warrant such theorizing. The patent does not say that an electrode is heated. Defendant's expert witness who testified concerning the Valbreuze patent did not claim that it had a heated electrode (Miller, 1 R. 682); plaintiff's witnesses testified that it did not have a heated electrode, and also that the Valbreuze idea was a useless thing (Weagant, 3 R. 1765; Waterman, 3 R. 2027); this was not contradicted by defendant's witnesses although Miller again testified concerning the Valbreuze patent (3 R. 2149); and the Court of Claims found that the patent "did not have a vacuum tube with heated filament but did propose a vacuum tube with two cold electrodes for use with radio frequencies as a rectifier" (findings, 1 R. 65).

Incidentally, defendant's footnote to page 131 of its brief that "Fleming himself, in his patent, acknowledged that when strong Hertzian waves are received, their alternating current will itself be sufficient to heat the filament to incandescence" is erroneous. It is true that the patent says that the filament may be incandesced by sufficiently strong "high frequency or low frequency alternating currents of electrical oscillations" (pat., p. 2, l. 99), but it does not say that the ordinary ether (Hertzian) waves are sufficiently strong for such operation (and they would not be).

The Valbreuze patent was applied for and issued in 1903, by a scientist who was familiar with vacuum tubes and wireless, as appears from his patent, and who undoubtedly knew of the "Edison effect" and perhaps many of the learned papers and discussions on it after the Edison patent was published in 1884. The fact that Valbreuze proposed

to employ the highly inefficient and practically useless point and ball type of rectifier, instead of the hot cathode-cold anode Fleming type, is strongly convincing that the "Edison effect" did not teach the Fleming invention.

5. THE FLEMING PATENT WAS VALID OVER THE PRIOR ART.

What Fleming did was patentable invention, whether tested by the "flash of creative genius" standard, *Cuno Engineering* v. *Automatic Devices*, 314 U. S. 84, 91, or the standard applied in *Williams Mfg. Co.* v. *United Shoe Mach. Co.*, 316 U. S. 364. He discovered that a vacuum tube containing a heated cathode and a cold anode, to the external circuit of which incoming alternating high frequency currents were applied, would rectify those currents and would "detect" the signals carried by those currents. This was new, useful, a discovery of great merit, the foundation of modern radio tubes, and worthy of the patents which were granted him here and in Great Britain.

The Fleming diode, two-electrode hot cathode tube, was widely used as a detector from 1907 to 1915, and relied upon for vitally important communication between ship and shore, being superseded about 1915 by the triode which differed only by the addition of a grid and associated battery, for amplification (plff's. brief, pp. 59-60). But Fleming's diode detector is in wide use today in radio broadcast receivers, in the form considered by this Court in *Detroit* v. *Hazeltine*, 318 U. S. 259, in which suit the Sixth Circuit Court of Appeals stated that "The patented device is used today in all well-known radio receivers manufactured in the United States", 117 F. 2d. 239, 240. Fleming made a real contribution to the practical radio art.

IV. The disclaimer was filed in time and its subject matter was proper.

A. The disclaimer was filed in time.

The Court of Claims said in its opinion that the patent was invalid because the disclaimer was filed too late (1 R. 106, 107) but did not make any finding on this point. The court referred (1 R. 106) to an 1890 observation of Fleming "that the current flowed only in one direction when an alternating current was used in connection with the lamp of an Edison apparatus" and "1897 similar statements made by Howell and Kennelly", and also to Fleming's statement in his patent that "I have discovered that if two conductors are inclosed in a vessel * * * the space between the hot and cold conductors possesses a unilateral electric conductivity, and negative electricity can pass from the hot conductor to the cold conductor, but not in the reverse direction" (pat., p. 1, l. 53 *et seq.*). The court erroneously thought that Fleming was "stating this feature in his patent specifications as new and patentable" (opinion, 1 R. 106), and that it was this discovery by Fleming which was disclaimed. Not at all; the disclaimer was with respect to frequencies other than high frequencies.

Claim 1 as issued was:

> "The combination of a vacuous vessel, two conductors adjacent to but not touching each other in the vessel, means for heating one of the conductors, *and a circuit outside the vessel connecting the two conductors.*"

This circuit was the one to which were applied alternating currents from an external source, which currents the

specification of the patent said might be either of low frequency or high frequency. The disclaimer limited the claim to "high frequency alternating electric currents or electric oscillations of the order employed in Hertzian wave transmission".

The 1890 Fleming paper did not invalidate claim 1 as originally filed, because Fleming did not apply external alternating currents to "a circuit connecting the two conductors", but merely heated his filament by an alternating current instead of a direct current (Fleming paper, 4 R. 3415). The 1892 Howell paper (5 R. 3459) containing some remarks by Kennelly (5 R. 3464) discussed the Fleming experiments.

Defendant's brief (p. 137-8) says that the disclaimer is invalid, because "Fleming had full knowledge of Edison's work before he filed his patent application" and the Fleming "claim 1 was patterned closely upon Edison's claim 5, covering Edison's device without change". This is essentially the same contention as above discussed (*supra*, p. 23), where the differences between Edison and Fleming are pointed out.

We think that claim 1 without the disclaimer was valid, because there was nothing in the prior art teaching the use of a hot cathode-cold anode vacuum tube, producing a one-way electron stream inside the tube from alternating currents applied to an external circuit including the cathode. However, the test is not whether the claim would or would not have been sustained, but whether there was unreasonable delay after the patentee became "aware that he has claimed more than he has invented or described" and until then "the allowance of his claim by the Patent Office raises such a presumption in its favor that he may rely on its

validity until a court of competent jurisdiction decides that it is broader than his real invention", *Ensten* v. *Simon Ascher*, 282 U. S. 445, 453. In the present case, it is plain that Fleming did not consider that the "Edison effect" or his 1890 experiments on it were more than observations from which his discovery and invention resulted, as appears from his 1905 paper where he states that he had recently returned to his 1890 observations and "it seemed quite possible that such a device would provide us with a means of rectifying electric oscillations and making them measurable on an ordinary galvanometer" (5 R. 3141). There is nothing in the record to justify the Court of Claim's view that Fleming must have known, when taking out his patent, that his 1890 experiments invalidated claim 1 (opinion, 1 R. 106). It is at least as probable that the Wehnelt German article, cited against the Fleming patent in the *Marconi* v. *De Forest* litigation, caused the disclaimer, it being plain common sense to avoid unnecessary argument, by limiting the claim to the particular subject matter of the *Marconi* v. *De Forest* suit, namely, the radio tubes used by defendant, which were used in connection with high frequency current (plff's. main brief, p. 73).

B. The subject matter of the disclaimer was proper.

Defendant's brief (p. 138 *et seq.*), asserts that the form of the disclaimer is improper and, therefore, that the disclaimer is invalid. This contention is unsound, and the Court of Claims did not so find or state.

This Court has often considered the form of disclaimers, sustaining some and invalidating others. The controlling principle of the decisions has been that a disclaimer narrowing the disclosed invention, as by limiting a claim to a

specific type of its general class or by deletion of unnecessary parts, is valid, but that a disclaimer which broadens the patent, or which changes the claimed combination, as by adding a new element, is invalid.

Disclaimers were sustained in *Silsby, et al.* v. *Foote*, 61 U. S. 378, the disclaimer limiting a broad claim for automatic stove opening mechanism to heat regulation; *Dunbar* v. *Myers*, 94 U. S. 187, disclaiming a single plate apparatus and claiming only a two plate apparatus (p. 192-194); *Hurlbut* v. *Schillinger*, 130 U. S. 456, limiting a process of forming blocks to the use of tar paper or its equivalent (p. 465); *Carnegie Steel* v. *Cambria*, 185 U. S. 403, 405, etc. Many other similar decisions are discussed in *Electrical Accumulator* v. *Julien Electric Co.*, 38 Fed. (C. C. S. D., N. Y.) 117, 134, *et seq.*

Altoona Publix v. *American Tri-Ergon*, 294 U. S. 477, considered the question of the form of disclaimers, incidentally referring to the disclaimer now before this Court. In the *Altoona* case, the disclaimer was held invalid, because it added a new element to the claim, namely, a fly wheel (pp. 490, 491). But this Court did not hold or intimate that a limiting disclaimer was improper, observing in the footnote to page 490 that disclaimers had been upheld

> "where the elimination from the patent of the matter not relied upon did not operate to enlarge the monopoly of the patent, but narrowed it . . . by limitation of a claim or specification by deletion of unnecessary parts, *Carnegie Steel Co.* v. *Cambria Iron Co.*, 185 U. S. 403, 435, 436; *Marconi Wireless Telegraph Co.* v. *DeForest Radio Telephone & Telegraph Co.*, 243 Fed. 560, 565 (C. C. A. 2nd), or by limiting the claim to a specific type of the general class to which it was applied, *Minerals Separation, Ltd.* v.

Butte & Superior Mining Co., 250 U. S. 336, 354; *United Chromium Inc.* v. *International Silver Co.*, 60 F. (2d) 913, 914 (C. C. A. 2d); *Seiberling* v. *Thropp's Sons Co.*, 284 Fed. 746, 756, 757 (C. C. A. 3rd)".

The *Marconi* v. *De Forest* case above cited sustained at the page referred to (565) the disclaimer here under consideration.

In *Milcor* v. *Fuller*, 316 U. S. 143, the courts below invalidated certain claims because disclaimers added new elements to the claims, and this Court affirmed. One disclaimer added a particular kind of flange to one claim, and the other disclaimer added a particular kind of a strip to another claim, this Court saying (p. 146) "the revised patent includes new elements which were not present in the original".

The disclaimers were there held improper because they did "more than delete a 'distinct and separable matter . . . without mutilating or changing what is left standing' ". The Fleming disclaimer, on the other hand, merely deletes a separable matter (use with low frequencies), without changing what is left (use with high frequencies).

Thus the disclaimer in the present case is like those referred to in the above quotation from the *Altoona* opinion (and, indeed, is one of them), and in the *Silsby*, *Dunbar* and *Hurlbut* decisions. It specifically limited broad claims for certain electrical apparatus to use "in connection with high frequency alternating currents or electrical oscillations of the order employed in Hertzian wave transmission" (disclaimer). These claims originally might have been argued to have to read upon some earlier work, and therefore been held invalid. The invention that Fleming made was to transform a laboratory experiment of scientific curiosity

and speculation into a practical device of the highest possible utility in the radio art, no one before Fleming knowing that a thing which produced unidirectional currents would rectify oscillations of the order used in radio communication, or that a thing which would rectify would detect, *i.e.*, act upon radio frequency currents carrying signal components so as to make the latter perceptible, *Marconi v. De Forest*, 2 Cir., 243 F. 560, 563, 564.

The Fleming patent plainly discloses that the invention is to be used in radio communication. The only apparatus shown in the drawings is radio apparatus, and the specification (pat. p. 1, l. 11, *et seq.*) states that the invention "relates to certain new and useful devices for converting alternating electric currents, and *especially* high-frequency alternating electric currents or electric oscillations" (pat. p. 1, l. 11, *et seq.*), "feeble electric oscillations, such as are employed in Hertzian-wave telegraphy" (*id.*, p. 1, l. 17), etc. Under such circumstances, it was proper to narrow the monopoly of the patent "by limitation of a claim or specification by deletion of unnecessary parts" or "by limiting the claim to a specific type of the general class to which it relates", *Altoona* opinion, *supra*.

Fleming made a real invention, which was clearly described in his specification. Limitation of specification and claims to that invention was proper, because "the disclaimer statute is remedial, and intended for the protection of both the patentee and the public", *Triplett v. Lowell*, 297 U. S. 638, 645; "The power to disclaim is a beneficial one, and ought not to be denied, except where it is resorted to for a fraudulent and deceptive purpose", *Sessions v. Romadka*, 145 U. S. 29, 40.

The form of the disclaimer was not improper.

V. The Fleming claims were infringed.

Defendant's argument on the issue of infringement of the Fleming claims 1 and 37 in suit (deft's. brief, p. 141, *et seq.*) is not that the claims do not read upon defendant's tubes (except as to tubes used as audio frequency amplifiers, brief, p. 158*), but it is, in essence that the De Forest improvement of a grid and a local battery avoids infringement. However, the real question is not whether defendant's tubes are better than the diode shown in the Fleming patent, but whether the Fleming invention is the foundation and basis of these tubes.

Cochrane v. *Deener*, 94 U. S. 730, 787:

> "The defendants admit that the process has produced a revolution in the manufacture of flour; but they attribute that revolution to their improvements. It may be, as they say, that it is greatly due to these. But, it can not be seriously denied that Cochrane's invention lies at the bottom of these improvements, is involved in them, and was itself capable of beneficial use, and was put to such use. It had all the elements and circumstances necessary for sustaining the patent, and cannot be appropriated by the defendants, even though supplemented by and enveloped in the very important and material improvements of their own."

*Defendant's point here is that claims 1 and 37 are limited to use in connection with radio frequencies, claim 37 being also limited to "a detector", and defendant's tubes merely amplify audio frequencies after detection by an associated tube. But both claims are infringed, because the tubes are used in connection with radio frequencies, as they amplify the audio frequencies carried by the radio frequencies, and the tubes are part of a detector, which would not "detect" without them (plff's main brief, p. 67).

The Fleming invention consists of an evacuated tube, a hot electrode (cathode), a cold electrode (anode), and an electrical circuit so arranged that when high frequency alternating currents carrying signals are applied to the tube circuits there is produced a unidirectional current between the hot electrode and cold electrode, containing the signal in the form of pulsations. This is found in defendant's tubes, whether used to detect or to amplify (the latter including regenerative feed back and oscillations, plff's. main brief, p. 56), and defendant's tubes would not operate if their cathodes were not hot and the alternating currents applied to the tube were not rectified to produce a unidirectional current through the tube. This should decide the issue of infringement in favor of plaintiff.

Defendant's discussion of the functions and operations of the grid in its tubes (brief, p. [illegible], *et seq.*) are irrelevant, because there is no question but that the grid was an improvement, plaintiff in the *Marconi* v. *De Forest* case agreeing that "De Forest in his three-electrode Audion has undoubtedly made a contribution of great value to the art", 236 Fed. 955 (Sept. 20, 1916).

The grid, whether the tube is used for detecting or amplifying, acts upon and utilizes *the Fleming uni-directional flow of electrons from heated cathode to anode inside the tube*. Such action is necessary in the operation.

When a triode tube is detecting, the grid, because of rectification of the radio frequency currents by the tube, accumulates on it the audio frequency variations, which are the signals, and are carried by the radio frequency currents. The Court of Claims so found (finding LXXV, 1 R. 69), and although it correctly says that after the rectification has charged the grid "rectification of the full

high radio-frequency waves ceases", it is obvious that rectification is necessary. The court appears to have been so impressed with the importance of the grid that it overlooked the fact that there must be a uni-directional rectifying current in order for the tube to operate. Defendant's brief (footnote, p. 161) says with respect to its tube that "one of its most important characteristics is that it is uni-directional only", but it is more than that, it is essential. The grid impresses its audio frequency variations upon *the uni-directional electron stream from heated cathode to anode*, which is a part of the cathode-anode circuit, and the variations operate an indicator. In Fleming, the audio frequency variations of the incoming radio freqency currents themselves operate, in the cathode-anode circuit, an indicator, Fleming of course using both rectification and the same uni-directional stream.

When a triode tube is amplifying, the grid varies with all the variations of the incoming currents, and impresses all these variations upon *the uni-directional electron stream from heated cathode to anode*, the resulting variations in the cathode-anode circuit then operating any desired device, including a following tube. Fleming does not disclose any amplification.

If the Fleming invention was the contribution to the radio art of an invaluable tool, namely, a hot cathode-cold anode tube with uni-directional electron stream carrying radio frequency variations, as was held in *Marconi* v. *De Forest*, and we think rightly, defendant's tubes infringe, because they use that invention, which is necessary to any function performed by the grid.

In connection with the *Marconi* v. *De Forest* case, defendant's brief (p. 169, *et seq.*) repeats the error of the

Court of Claims that there was no issue of infringement in that case (1 R. 112), although that error was pointed out in plaintiff's main brief (pp. 68, 69). As this error undoubtedly influenced the court below, it is desirable to make perfectly clear that the question of whether the De Forest triode tubes infringed the Fleming patent was contested.

In the district court, 230 Fed. 942, the defendants argued vigorously that the De Forest triodes did not infringe the Fleming patent, the district court stating (p. 951):

> "We now come to what I think is the only substantial question in the case—the infringement claimed against defendants."

Defendants alleged there, as defendant does here, that the addition of the grid and a local battery to the Fleming tube avoided infringement, and the operation of these things was much discussed (p. 952, *et seq.*).

In the circuit court of appeals, 243 Fed. 500, infringement again was contested, the court saying (p. 504), "it is upon the question of infringement that this record has been filled with theories", and again the action of the grid and local battery are considered, including their legal effect on the issue of infringement.

Defendant's brief (p. 171) quotes from the district court's opinion, 230 Fed. 953, "In reading this literature it must be remembered that both sides agree that the De Forest two-element and three-element bulbs operate *on the same principle*". By "same principle" was meant the principle of "unilateral conductivity or, in other words, a rectifier permitting current to flow in one direction only, *viz.*, from plate to filament and from grid to filament", as appears from the same page of the opinion. In the present case there is no

dispute that both the Fleming and De Forest tubes have this "unilateral conductivity". But the question there, as is the question here, was whether the addition of the grid and local battery avoided infringement.

Defendant's brief (p. 171) also quotes a similar statement from the opinion of the circuit court of appeals, 243 Fed. 405, in considering the issue of infringement of some De Forest counterclaim patents (not the Fleming patent) by Marconi diodes and triodes, where it was said "it is agreed that the 'two' and 'three electrode audions' operate on the same basic principle", 243 Fed. 405. Here again the "principle" was unilateral conductivity, and there was no agreement that the De Forest triodes infringed the Fleming patent. And, as above pointed out, infringement was contested in the court of appeals as well as in the district court.

The Fleming patent was infringed, if it contains patentable subject matter over the prior art, which it does.

CONCLUSION

This case is not like *Detrola* v. *Hazeltine*, 313 U. S. 259, where a 1927 diode circuit in the radio art was held unpatentable, nor *Cuno Engineering* v. *Automatic Devices*, 314 U. S. 84, where a 1929 cigar lighter patent was held invalid. The Marconi and Fleming inventions were made in the pioneer days of wireless, when little was known, and most of that was wrong.

Minerals Separation, Ltd. v. *Butte & Superior Mining Co.*, 250 U. S. 336, 345:

> "It is always difficult to recover the realities of a situation long past, such as we have here, but it is especially difficult when the importance of the

> discovery has led, as in this case, to extensive improvements in mechanical appliances for utilizing the invention and to large additions to the knowledge of the adaptability to the process of various oils, singly and in combination."

Kintner v. *Atlantic Communication Co.*, 249 Fed. (D. C., S. D., N. Y.), 73, 77-8, was a suit on a radio patent and the court in 1917 said:

> "In approaching the subject, it is extremely important to think, if possible, as of 1901. In this case, that is a troublesome task, because of the extraordinary progress in this art since then, and the consequent difficulty of discarding from consideration many items of after acquired knowledge. It is also necessary in this case not to accord undue importance to isolated suggestions in scientific papers and discussions. Such suggestions are not infrequently controlling in a well developed and well understood art where skilled men can readily appreciate the disclosure. In the infancy of a new, and, at the time, little understood, art, however, the alleged prior art, necessary to negative invention must be clear and doubts as to its meaning and disclosures should ordinarily be resolved in favor of the inventor."

The Marconi invention was a great advance in the practical art—it meant something useful to the public, and indeed was practically the only system employed for many years. At the risk of repetition, attention is again called to the unanimous verdict of the courts which considered it in the early days of the art, when the then realities of the situation could be more accurately appraised than today, those courts saying (plff's. main brief, p. 22), *National*

case (213 Fed. 841), a "conspicuous advance in wireless telegraphy" (p. 858); *Kilbourne & Clark* case (239 Fed. 328), "a real accomplishment" and the ideas involved in the patent "have proven of great value to the world" (pp. 335, 342); High Court of Justice, Chancery Division, "an entirely new and useful result" (4 R. 2557); and the Civil Tribunal of the Seine, in France, "a new and very important industrial result" and "a wonderful conquest" (4 R. 2641) and "the Marconi patent stands out as an unassailable monument until new discoveries are made" (4 R. 2674).

The Fleming invention was of even greater importance, because it contributed the hot cathode-cold anode tube to the radio art. The invention is widely used today in its original diode form, and also in the triode form, which, because of the De Forest grid and local battery, enables the tube to accomplish also the highly desirable result of amplification of electrical currents.

There was nothing in the prior art, which consists of merely laboratory experiments and unfruitful patented ideas, to anticipate the Marconi and Fleming patents. The multitude of prior papers and patents collected by defendant and contained in volumes 4 and 5 of the record are full of mistaken proposals and suggestions which led nowhere except to failures. It would have required ability of the highest order at that early time to have selected correctly the right principle to follow, even if it had been among the many advanced, which, however, was not the case.

If Marconi and Fleming made real inventions, as we believe, there is no substantial question but that their patents were infringed. The Court of Claims so declared with

respect to the Marconi patent, and it should have so found with respect to the Fleming patent, as indeed we have no doubt it would have, if the court had thought that Fleming was entitled to patent the high frequency rectifying operation described and claimed in his patent and upon which defendant's tubes depend for operation.

In Case 369, claims 1, 2, 3, 6, 8, 10 through 14, and 17 through 20 of the Marconi patent 763,772 should be held valid and infringed by the apparatus declared by the Court of Claims to infringe if the claims were valid; and claims 1 and 37 of the Fleming patent 803,684 should be held valid and infringed by defendant's triodes used as detectors or parts thereof, and as oscillators.

In Case 373, the judgment of the Court of Claims, that claim 16 of the Marconi patent was valid and infringed, and fixing compensation therefor, should be affirmed.

Respectfully submitted.

Petitioner,

vs.

THE UNITED STATES,

Respondent.

Motion and Notice of Motion

SIR:

PLEASE TAKE NOTICE that, upon the annexed affidavit of Abel E. Blackmar, Jr., verified the 25th day of November, 1942, the petitioner herein, Marconi Wireless Telegraph Company of America, by the undersigned, its counsel, hereby moves this Honorable Court for an order requiring respondent to reimburse petitioner for the cost of printing, and the fees of the Clerk of this Court for supervising the printing of, the required forty (40) copies of that portion of the printed transcript of the record herein which was included in the transcript and printed solely for use in connection with respondent's cross petition for a writ of certiorari (Case No. 373 of the October, 1942, Term of this Court) with respect to certain portions of the judgment

herein as to which petitioner has assigned no error, said portion of the printed transcript of the record comprising pages 2313 to 2522, inclusive, thereof, and for such other and further relief as may be proper in the premises.

Dated, November 25, 1942.

ABEL E. BLACKMAR, JR.,
RICHARD A. FORD,
Counsel for Petitioner.

To

THE HONORABLE THE SOLICITOR GENERAL
OF THE UNITED STATES,
Counsel for Respondent,

IN THE

SUPREME COURT OF THE UNITED STATES

OCTOBER TERM, 1942

No. 369

MARCONI WIRELESS TELEGRAPH COMPANY OF AMERICA,

Petitioner,

v.

THE UNITED STATES,

Respondent.

Affidavit

STATE OF NEW YORK)
COUNTY OF WESTCHESTER) ss.:

ABEL E. BLACKMAR, JR., being duly sworn, deposes and says:

That he is a member of the bar of this Court and of counsel for petitioner herein, and that he has been of counsel for petitioner throughout the proceedings in this cause in the court below since prior to the interlocutory judgment entered November 4, 1935, herein.

That this cause was instituted by petitioner in the Court of Claims of the United States, under the provisions of the Act of Congress of June 25, 1910 (amended July 1, 1918), U. S. Code, Title 35, Section 68, to recover compensation for the use, by respondent, of the subject matter of four

United States Letters Patent for invention, as more fully set forth in petitioner's Petition for Writ of Certiorari herein.

That the interlocutory judgment herein, among other things, held that claim 16 of Marconi patent No. 763,772 was valid and had been infringed by respondent. That thereafter, this cause was referred to a Commissioner of the Court of Claims to take the evidence on a proceeding to ascertain the amount of compensation to which petitioner was entitled by reason of respondent's infringement of said claim 16 and of certain claims of the Lodge patent No. 609,154, and to report thereon. That such report was made and the parties filed their exceptions thereto, which were duly heard by the Court of Claims. That said court thereupon rendered its final judgment herein, awarding compensation to petitioner for respondent's infringement of said claim 16 of the said Marconi patent and of the Lodge patent.

That, during the course of the accounting proceeding before the Commissioner, respondent introduced evidence directed to the issue of infringement of said claim 16 and argued, both before the Commissioner and before the Court of Claims, on final hearing, chiefly on the basis of such evidence, that the original decision of the Court of Claims on such issue was erroneous. That the Court of Claims, however, held that its interlocutory decision on this issue was the law of the case.

That, after the final judgment of the court below, deponent informed counsel for respondent that petitioner proposed to apply to this Court for a writ of certiorari with respect to the decision of the Court of Claims that the claims, *other than claim 16*, of the said Marconi patent were invalid and that the Fleming patent No. 803,684 had not been infringed. That deponent thereafter submitted to counsel for respondent a proposed transcript of the por-

tions of the record herein that deponent considered material to the errors which he intended to assign on behalf of petitioner; that this was done in the hope that the parties could agree on the record and thus avoid the difficulty, time, and great expense that would be involved both in the preparation of eight complete copies of the proposed record (both testimony and exhibits) for filing in the Court of Claims and for counsel, and in the submission of the record to the Court of Claims for settlement. That this portion of the record, including additional portions designated by counsel for respondent, was referred to, in correspondence between counsel, as "plaintiff's record".

That thereafter, counsel for respondent, in addition to designating such additional portions of plaintiff's record, also submitted, for inclusion in the proposed transcript, "extracts from the accounting testimony which the defendant desires to accompany its proposed cross-petition for certiorari, if the plaintiff's petition is allowed." (Letter of April 29, 1942, from Mr. C. V. Edwards, counsel for respondent, to deponent. The cross-petition is case No. 373 of the October, 1942, Term of this Court.) That this portion of the record, taken solely from the accounting proceeding and including additional parts designated by deponent, is material only to the issue of infringement of claim 16 of the said Marconi patent,—the subject matter of respondent's cross-petition,—and is not material to any of the issues assigned by petitioner, all of which were decided by the Court of Claims prior to the accounting proceeding. That, in correspondence between counsel, this portion of the record was referred to as "defendant's record".

That thereafter, counsel agreed upon the entire transcript of record—both those portions material to errors to be assigned by petitioner and those portions material to

errors to be assigned by respondent. That, prior to submission of the proposed transcript to the Court of Claims for certification, deponent was advised that the Court of Claims would not certify two records, one as plaintiff's record and the other as defendant's record. That the entire record was therefore submitted as a single record and has been printed as such for use both on petitioner's application for a writ of certiorari (No. 369) and on respondent's cross-petition (No. 373).

That petitioner moved, before the Court of Claims, for an order relieving it of the cost of certification of that portion of the record that was material solely to respondent's proposed cross-petition, but that the motion was denied without opinion. That, under Rule 101 of the Court of Claims, the Clerk's fee for preparing and certifying a transcript of the record for the purpose of a writ of certiorari is chargeable only when such transcript is "sought by plaintiff".

That the portion of the printed transcript of the record herein that is material solely to respondent's cross-petition is contained in pages 2313 to 2522, inclusive, thereof. That the said record was printed, in accordance with Rule 41 of this Court, under the supervision of the Clerk of this Court, and that the cost of printing, and of supervising the printing of, the entire record has been paid by petitioner.

That deponent is informed and believes that the cost of printing the required forty (40) copies of said pages 2313 to 2522, inclusive, of the transcript of the record amounted to Four Hundred and Eight and 85/100 Dollars ($408.85); and that the fee of the Clerk of this Court for supervising the printing thereof was approximately Eighty-one and 70/100 Dollars ($81.70).

WHEREFORE, deponent respectfully prays that this Court enter an order requiring respondent to pay to petitioner the sum of Four Hundred and Ninety and 55 100 Dollars ($490.55) to reimburse it for the cost of printing, and of supervising the printing of, said portion of the record.

ABEL E. BLACKMAR, JR.

Subscribed and sworn to before me

No. 369

MARCONI WIRELESS TELEGRAPH COMPANY OF AMERICA, PETITIONER

v.

THE UNITED STATES

ON PETITION FOR A WRIT OF CERTIORARI TO THE COURT OF CLAIMS

BRIEF FOR THE UNITED STATES IN OPPOSITION

OPINIONS BELOW

The opinion of the Court of Claims on the issues of validity and infringement of the patents in suit (R. 7–116) is reported in 81 C. Cls. 671. The opinion of the Court of Claims on the accounting proceedings (R. 117–182) is not yet officially reported.

JURISDICTION

The interlocutory judgment of the Court of Claims concerning validity and infringement, in

pursuance of which an accounting was held, was rendered November 4, 1935 (R. 75); the final judgment after accounting proceedings was rendered April 6, 1942 (R. 182). The petition for a writ of certiorari was filed September 2, 1942 (R. 2524), pursuant to an extension of time granted by the Chief Justice (R. 2523). The jurisdiction of this Court is invoked under Section 3(b) of the Act of February 13, 1925, as amended.

QUESTIONS PRESENTED

(1) Whether the Court of Claims erred in holding the Marconi patent, No. 763,772, invalid as to all the claims in suit other than Claim 16 (*viz.* as to Claims 1, 2, 3, 6, 8, 10–14 and 17–20).

(2) Whether the Court of Claims erred in holding that Claims 1 and 37 of the Fleming patent, No. 803,684, had not been infringed by the United States.

STATUTE INVOLVED

The Act of June 25, 1910, c. 423, 36 Stat. 851, as amended by the Act of July 1, 1918, c. 114, 40 Stat. 704, 705 (35 U. S. C. § 68), to the extent pertinent reads as follows:

> That whenever an invention described in and covered by a patent of the United States shall hereafter be used or manufactured by or for the United States without license of the owner thereof or lawful right to use or manufacture the same, such owner's remedy shall be by suit against the United States in the Court of Claims for the recovery of

his reasonable and entire compensation for such use and manufacture: * * * *Provided further*, That in any such suit the United States may avail itself of any and all defenses, general or special, that might be pleaded by a defendant in an action for infringement, as set forth in Title Sixty of the Revised Statutes, or otherwise. * * *

STATEMENT

On July 29, 1916, petitioner brought this suit in the Court of Claims under the Act of June 25, 1910, to recover compensation for the alleged unauthorized use by the United States of inventions alleged to have been covered by four patents, two issued to Guglielmo Marconi, one to Sir Oliver Lodge, and one to Sir John Ambrose Fleming. One Marconi patent (reissue No. 11,913) was held not to have been infringed, and as to this no review is sought by petitioner. The Lodge patent (No. 609,154) was held to be valid and infringed, and is not here involved. The remaining two patents are Patent No. 763,772 to Guglielmo Marconi, granted June 28, 1904 (Claims 1, 2, 3, 6, 8, 10, 11, 12, 13, 14, 16, 17, 18, 19, and 20 involved in suit), and Patent No. 803,684 to John Ambrose Fleming, granted November 7, 1905 (Claims 1 and 37 involved in suit).

The court below, in its interlocutory judgment of November 4, 1935, held that all the claims in suit of Marconi Patent No. 763,772, except Claim

16[1] were invalid, and that Fleming Patent No. 803,684 had not been infringed by the defendant (81 C. Cls. 671; R. 75). These holdings were embodied by the court in the ultimate findings of fact (R. 117) made in connection with its final decision of April 6, 1942. The final judgment (R. 182) entered on that date awarded compensation to plaintiff in the amount of $42,984.93, plus interest, for infringement of Claim 16 of the Marconi patent, and in the additional amount of $34,827.79, plus interest, for infringement of the Lodge patent (not here involved).

The evidentiary findings of fact of the court below, supporting the ultimate findings of fact referred to above, may be briefly summarized as follows:

(a) *Marconi Patent No. 763,772 (all claims involved in suit other than Claim 16)* is directed to the tuning of wireless telegraph transmitters and receivers.

The pre-existing transmitter alleged to have been improved consisted of an antenna-circuit (also known as the radiating-circuit) and a charging-circuit. The antenna-circuit had an antenna at one end and a connection to earth at the other; the charging-circuit was coupled to the antenna-circuit through a transformer. The charging-

---

[1] The defendant has filed a petition (No. 373) praying that in the event this Court grants the petition here involved (No. 369), but only in that event, a cross-writ of certiorari be issued to review that portion of the final judgment which awards damages against the United States for infringement of Claim 16 of the Marconi patent.

circuit contained a spark-coil, a charging condenser, and a spark gap—all three being known means for producing high frequency electrical oscillations (Finding XLIII, R. 38).

The pre-existing receiver alleged to have been improved likewise consisted of two circuits: the antenna-circuit which received the oscillations had an antenna at one end and a connection to earth at the other; and the detector-circuit which was coupled to the antenna-circuit through a transformer. Detecting and translating means, as a coherer and telegraph sounder, were connected in the detector-circuit (Fig. 13, Lodge patent, Ex. 20 R. 26), Finding XXVII, R. 24).

The alleged improvement of the Marconi patent (as embodied in all claims involved in suit except Claim 16) consisted in adjusting the inductance and capacity of either the two circuits at the transmitter or the two circuits [1] the receiver, or all four of these circuits to bring them into resonance to the same frequency or wave-length (Findings XXXVIII–XLIII, R. 31–38).

The court below found as facts that the alleged improvement of these claims was anticipated by the prior art (Findings LVII, LVIII, LIX, LXI, LXII, R. 56–60) as follows:

CLAIMS OF MARCONI PATENT INVOLVED IN SUIT	ANTICIPATING PRIOR ART
All claims for four-circuit tuning (except Claim 16)[1]	Stone Patent No. 614,756; and Tesla Patent No. 645,576 in conjunction with Lodge Patent No. 609,154

[1] Claim 16 was sustained for another feature. See cross petition for certiorari in No. 373 this Term, 1942.

[In addition, as anticipating prior art with respect to certain of these claims the Court found]

Claims 2, 12, 18, 39	Marconi Patent No. 627,650
Claims 1, 3	Lodge Patent No. 609,154, Fig. 4
Claim 2	Lodge Patent No. 609,154, Figs. 12, 13
Effecting four-circuit tuning by means of a variable inductance	Lodge Patent No. 609,154

(b) *Fleming Patent No. 803,684 (Claims 1 and 37)* disclosed a radio receiving circuit using as a rectifying detector the two-electrode tube of Edison patent No. 307,031 (Findings LXIV, LXX, LXXI, R. 60, R. 64–67). Fifteen years before the filing of this patent application in 1905 Fleming described in publications the unilateral conductivity of the Edison tube and its ability to rectify alternating currents when connected in a circuit as defined in Claim 1 of the Fleming patent. In 1915, ten years after his patent issued—long after the three-electrode tube had been invented and employed in radio apparatus as detector, amplifier and oscillator, and after the United States had used substantial quantities of three-electrode tubes as detectors and amplifiers—Fleming's assignee filed a disclaimer limiting "the combinations of elements" in certain claims, including Claim 1, and making other modifications in the specification (Findings LXV, LXXI, R. 62, 74).

The opinion of the court below indicated that the Fleming patent may be invalid because the new use it made of the "Edison effect" lacked invention (R. 104–105), and because of insufficiency and unreasonable delay in filing the disclaimer (R. 105–107). However, these matters are not included in

As modified by the disclaimer, the Fleming patent does not include all uses for the electron emissions from the heated electrode of the tube of the Edison patent, nor all uses for such emissions in connection with radio frequencies, but relates only to a *rectifying* use of such emissions of the Edison tube in connection with *alternating* currents of radio frequencies (Finding LXXII, R. 67).

All the alleged infringements comprise use of the three-electrode vacuum tubes of De Forest and purchase of such tubes and apparatus for use (Finding LXXV, R. 69). The defendant's structures used the De Forest three-element vacuum tubes as detectors and amplifiers. In these arrangements (both detector and amplifier), the hot filament and plate of the Edison tube were connected with a *direct current* battery circuit polarized so that current would flow, and the translating device, i. e., headphone, was placed in this battery circuit. In the detector arrangement, the incoming alternating current signal was connected through a grid condenser to a grid placed in the space between the hot filament and the plate so that the audio-components of the received oscillations would alternatingly stop and permit flow of a larger local battery current (Finding LXXV, R.

---

the findings of fact on which the judgment is based (R. 60–74), since those findings are restricted to the pivotal issue of infringement (R. 75).

69); in the amplifier arrangement, the alternating current of audio frequency was also applied to the grid to control increase or decrease of a larger current in the local battery circuit (Finding LXXVI, R. 72).

The court below found that insofar as defendant's structures and the invention disclosed in the Fleming patent had anything in common, the common matter had been disclosed in the earlier Edison patent (Finding LXXII, R. 67); that the Fleming patent was limited to his manner of applying the so-called "Edison effect" (Finding LXXII, R. 67); that the defendant's manner of using the "Edison effect" differed in means, mode of operation and result from that of Fleming (Findings LXV–LXXX, R. 62–74); and that, therefore, defendant's structures did not infringe the Fleming patent (R. 116; Finding I, R. 117).

ARGUMENT

In making the evidentiary findings in support of its ultimate findings as to invalidity of the Marconi patent (except Claim 16) and noninfringement of the Fleming patent, the court below analyzed in detail the prior art relied upon by defendant and pointed out wherein it anticipated or limited the subject matter and claims of these patents. Petitioner has not challenged these analyses, nor has it charged, or made any showing, that there is a lack of substantial evidence to sustain the findings, or that any ultimate finding is not sustained by the

evidentiary findings. Likewise no contention has been made, nor could it have been made, that the court below failed to make any finding of fact on a material issue. There is thus no basis for review under the 1939 amendments to the Act of February 13, 1925, providing for review by certiorari of decisions of the Court of Claims.[4]

As the sole reasons for allowing the writ petitioner urges (1) an alleged conflict between the conclusions reached below and several decisions of the lower federal courts, and (2) recommendations of an administrative board in 1921 that Congress enact legislation awarding petitioner a greater sum

---

[4] Section 3 (b) of the Act of February 13, 1925, c. 229, 43 Stat. 936, as amended by the Act of May 22, 1939, c. 140, 53 Stat., part 2, 752, provides that in cases of certiorari to the Court of Claims, "the Supreme Court shall have authority to review, in addition to other questions of law, errors assigned to the effect that there is a lack of substantial evidence to sustain a finding of fact; that an ultimate finding or findings are not sustained by the findings of evidentiary or primary facts; or that there is a failure to make any finding of fact on a material issue."

Indeed, the only questions involved—the issue of invalidity with respect to the Marconi patent, and the issues of scope of claims and of infringement with respect to the Fleming patent, are purely factual. *United States* v. *Esnault-Pelterie*, 299 U. S. 201; 303 U. S. 26, 29. And even before the Act of May 22, 1939, decisions of the Court of Claims upon such matters were not subject to review by this Court except where the ultimate findings were not sustained by the evidentiary findings. *United States* v. *Esnault-Pelterie*, 303 U. S. 26. The decision of such issues in the federal courts will not ordinarily be reviewed except to resolve a conflict of decision between circuit courts of appeals. *Keller*

than it has recovered below. Neither of these grounds justifies the issuance of the writ.

1. *The decision below does not conflict with decisions of other federal courts on either of the two questions in this case.*

The Marconi patent here involved was considered by the federal courts in three reported cases, but, as the Court of Claims pointed out in its decision of this case (R. 95–102), none of these adjudications is inconsistent with the result reached below. In *Marconi Wireless Telegraph Co. of America* v. *National Electric Signaling Co.*, 213 Fed. 815 (E. D. N. Y.), the District Judge held the Marconi patent valid and infringed, but the defense of the prior art Stone patent (which the Court of Claims relied upon in this case to hold the patent invalid) was neither presented nor referred to. *Marconi Wireless Telegraph Co. of America* v. *De Forest Radio Telephone & Telegraph Co.*, 225 Fed. 65 (S. D. N. Y.), affirmed 225 Fed. 373 (C. C. A. 2), involved a motion for preliminary injunction under the Marconi patent. The court, merely issuing preliminary relief against infringement, did not pass upon the question of validity. In *Marconi Wireless Telegraph Co.* v. *Kilbourne & Clark Mfg. Co.*, 239 Fed. 328 (W. D. Wash.), affirmed 265

---

v. *Adams-Campbell Company*, 264 U. S. 314, 319; *Layne & Bowler Corporation* v. *Western Well Works, Inc.*, 261 U. S. 387; *cf. General Talking Pictures Corp.* v. *Western Electric Company*, 304 U. S. 175. There is no such conflict here.

Fed. 644 (C. C. A. 9), the district court, again not passing upon validity, merely held the Marconi patent not to have been infringed. While the "Stone" defense was before the court, it was presented solely to sustain the defense of "noninfringement of the invention as limited by the prior art," and the circuit court of appeals in affirming the decision as to noninfringement expressly recognized defendant's position in this respect (265 Fed. 646). The significance of the court's language as to validity is thus considerably diminished. Of greater significance is the fact, as the court below recognized (R. 97–99), that anticipation by Lodge Patent No. 609,154 taken with Tesla Patent No. 645,576—the other basis for the Court of Claims' conclusion of invalidity—was not considered in that decision.

The Fleming patent was considered by the federal courts in two cases, neither of which involved the question of infringement here presented. In *Marconi Wireless Telegraph Co.* v. *De Forest Radio Telephone & Telegraph Co.*, 236 Fed. 942 (S. D. N. Y.), the plaintiff sued for infringement of the Fleming patent by the use of the three-electrode tube, alleging that it was the same in principle as the Fleming two-electrode tube. The defendant agreed they were the same in principle, but urged that the hot-gas tube patents of defendant, which were earlier than the Fleming patents, were also the same in principle. The court held the hot-gas

tube patents to be different in principle, and the Fleming patent to be valid and infringed. The Circuit Court of Appeals for the Second Circuit affirmed (243 Fed. 560), noting that both parties agreed the two-element and three-element tubes were the same in principle. In 261 Fed. 393, the district court extended the decree to oscillators, on the theory that the Fleming valve was inherently capable of oscillating. Since there was no conflict between the parties in that litigation as to the point most important to the issue of infringement here involved—*viz.*, whether the two-electrode and three-electrode tubes are different in principle—the decision cannot be deemed a holding in conflict with the result reached below.[1] Nor did *Radio Corporation of America* v. *Radio Audion Co.*, 278 Fed. 628 (Del.), pass on the point here involved.[2]

The decisions of the British and French courts to which petitioner refers plainly have no application, being rendered under different patents and different statutory standards.

2. Petitioner makes reference to the recom-

---

[1] In this connection it should be noted that the findings and opinion of the Court of Claims in the present case as to the operation of the three-electrode tube are in accord with the analysis thereof made by this Court in *De Forest Radio Co.* v *General Electric Co.*, 283 U. S. 664.

[2] In that case, the district court, without explanation, but apparently following the *De Forest* case (Pet. 22, note 26) granted a preliminary injunction under the Fleming patent as to detectors, but refused to grant restraint as to amplifiers and oscillators.

mendation of an Interdepartmental Board in 1921 that legislation be enacted granting petitioner $1,250,000 for respondent's use of the Marconi, Fleming, and Lodge patents (Pet. Br. p. 20). Not only is this factor irrelevant, but whatever significance is sought to be attached to it is virtually nullified by petitioner's admission that the recommendation, which was based upon an *ex parte* presentation by petitioner, was without prejudice and not binding upon the Government, and was rejected by Congress (Pet. Br. pp. 20, 26).

Since the patents in suit have long since expired (Pet. Br. 12), no question of importance with respect to the patents is here involved. And no novel question of law is presented by this case.

CONCLUSION

The decision of the court below is correct. There is no conflict and no question of importance is involved. It is therefore respectfully submitted that the petition for a writ of certiorari should be denied.

No. 369

MARCONI WIRELESS TELEGRAPH COMPANY OF AMERICA, PETITIONER

v.

THE UNITED STATES

ON WRIT OF CERTIORARI TO THE COURT OF CLAIMS

BRIEF FOR THE UNITED STATES

OPINIONS BELOW

The opinion of the Court of Claims on the issues of validity and infringement of the patents in suit (I R. 7–116[1]) is reported at 81 C. Cls. 671; its opinion on the accounting proceedings (I R. 117–182) is not yet officially reported.

JURISDICTION

The interlocutory judgment of the Court of Claims concerning validity and infringement, pur-

[1] The record citations refer to the volume and page.

suant to which an accounting was held, was rendered November 4, 1935 (I R. 75); the final judgment after the accounting proceedings was rendered April 6, 1942 (I R. 182). The petition for a writ of certiorari was filed on September 2, 1942 (III R. 2524), pursuant to an extension of time granted by the Chief Justice (III R. 2523), and was granted on December 14, 1942. The jurisdiction of this Court is invoked under Section 3 (b) of the Act of February 13, 1925, as amended.

QUESTIONS PRESENTED

I. Whether the Court of Claims erred in holding the Marconi patent No. 763,772 invalid as to all the claims in suit other than claim 16.

II. If the answer to the first question is in the affirmative, whether the Marconi patent was infringed by defendant's apparatus.

III. Whether the Court of Claims erred in holding that claims 1 and 37 of the Fleming patent No. 803,684 were not infringed by the United States.

IV. If the answer to the third question is in the affirmative, whether the Fleming patent was invalid for—

(1) anticipation by the prior art;

(2) unreasonable delay in disclaiming a part of the patent lacking invention; or

(3) impropriety of the subject matter of the disclaimer.

STATUTES INVOLVED

The Appendix, pp. 175–178, *infra*, contains the pertinent provisions of the statutes involved.

STATEMENT

On July 29, 1916, petitioner Marconi Wireless Telegraph Company of America (herein called "plaintiff") brought this suit in the Court of Claims under the Act of June 25, 1910, to recover compensation for the allegedly unauthorized use by the United States (herein sometimes called "defendant") of inventions alleged to have been covered by four United States patents, two issued to Guglielmo Marconi, one to Sir Oliver Lodge, and one to Sir John Ambrose Fleming.

The court below held that one Marconi patent, reissue No. 11,913, was not infringed (I R. 117), and that the Lodge patent No. 609,154 was valid and infringed (I R. 117). As to these, no review has been sought by either party.[1] The court below further held that claim 16 of Marconi patent No. 763,772 was valid and infringed (I R. 117), and after accounting proceedings rendered final judgment on April 6, 1942, awarding plaintiff compensation in the amount of $42,984.93 plus interest (I R. 182). The decision concerning claim 16 is now before this Court in *The United States* v.

[1] The final judgment rendered after the accounting proceedings awarded plaintiff $34,827.70 plus interest for infringement of the Lodge patent (I R. 182).

Marconi Wireless Telegraph Company of America, No. 373, this Term.

The remaining claims in suit of Marconi patent No. 763,772[1] were held invalid (I R. 117), and the Fleming patent No. 803,684 was held not infringed (I R. 117). This decision is the subject of the present proceeding.

The findings of fact of the court below, briefly summarized, were:

Marconi Patent No. 763,772 granted on June 28, 1904, was directed to the tuning of wireless telegraph transmitters and receivers, and claimed an improvement therein. The preexisting transmitter alleged to have been improved by Marconi consisted of a charging circuit and an antenna circuit. The charging circuit of the preexisting transmitter, which generated the oscillations, contained means for producing high frequency electrical oscillations, namely, a spark coil, a charging condenser and a spark gap. The antenna circuit, which transmitted the oscillations, had an antenna at one end and a connection to earth at the other. The charging circuit and the antenna circuit were coupled together by a transformer. (Finding XLIII; I R. 38.)

The preexisting receiver alleged to have been improved by Marconi likewise consisted of two circuits: an antenna circuit and a detector circuit. The antenna circuit, which received the

[1] Claims 1, 2, 3, 6, 8, 10, 11, 12, 13, 14, 17, 18, 19, and 20.

oscillations, had an antenna at one end and a connection to earth at the other. The detector circuit contained a means for detecting the transmitted oscillations (such as a coherer) and a means for translating them (such as a telegraph sounder). The detector circuit and the antenna circuit were coupled together by a transformer (Finding XXVII; I R. 24).

The alleged improvement of the Marconi patent (as embodied in all claims involved in suit except claim 16) consisted in adjusting the inductance and capacity of either the two circuits at the transmitter or the two circuits at the receiver, or all four of these circuits, in order to tune or bring them into resonance to the same frequency or wave length (Findings XXXVIII–XLIII; I R. 31–38).

The court below found that this alleged improvement was anticipated and consequently invalidated by the prior art (Findings LVII–LIX, LXI, LXII; I R. 56–60). It made findings as to the subject matter of the prior art and of the claims in suit, showing, by direct comparison, the lack of novelty in the latter (Findings XXVII, XL–XLIII, LI–LIX, LXI–LXII; I R. 23, 32–40, 45–57, 57–59). More specifically, it found or held that all claims for four-circuit tuning (except claim 16, which was sustained on account of a feature not relevant here) were anticipated by Stone patent No. 714,756 (Finding

LVIII; 1 R. 57), and by Tesla patent No. 645,576 read in conjunction with Lodge patent No. 609,154 (1 R. 98).*

Fleming Patent No. 803,684 granted on November 7, 1905 (claims 1 and 37 in suit), disclosed a radio receiving circuit using as a rectifying detector the two-electrode tube of Edison patent No. 307,031 (Findings LXIV, LXX, LXXI; 1 R. 60, 64–67). The unilateral conductivity of the Edison tube and its ability to rectify (by changing to direct current) alternating currents when connected in a detector circuit as defined in claim 1 of the Fleming patent had been described in publications as early as 1890, fifteen years before Fleming filed his patent application; and it was such rectification, with the same detector circuit, that claim 1 of the Fleming patent described (Finding LXXI; 1 R. 67). In 1915, ten years after the patent issued, plaintiff as Fleming's assignee filed a disclaimer purport-

* The Marconi claims for effecting four-circuit tuning by means of a variable inductance were also found to have been anticipated by the Lodge patent, and six Marconi claims were found to be additionally anticipated in other prior art, as follows (Findings LIX and LXI; 1 R. 57):

Marconi Patent No. 763,772	*Anticipating Prior Art*
Claims 2, 13, 18, 19.	Marconi Patent No. 627,650.
Claims 1, 3.	Lodge Patent No. 609,154, Fig. 4.
Claim 2.	Lodge Patent No. 609,154, Figs. 12, 13.

ing to limit the field of use of certain claims (including claim 1) to the use of the two-electrode rectifier, without change, to rectify alternating currents of high (or Hertzian wave) frequencies (Finding LXXII; 1 R. 67). The Edison two-electrode rectifier used by Fleming consisted of two elements within a vacuous enclosure: a filament heated to cause it to emit electrons, and a colder plate in proximity to but not touching the filament. The two elements were connected by a circuit outside the tube, and, because the electrons flowed through the tube only from the hotter to the colder element, alternating current introduced into the circuit from an external source would pass in only this one direction through the vacuous space between the elements, thus resulting in rectification.

The alleged infringements by the defendant consist of the use of the three-electrode vacuum tubes of DeForest, and the purchase of such tubes and apparatus for use in receivers and transmitters (Finding LXXV; 1 R. 69). The defendant's receivers used the DeForest three-electrode vacuum tubes as detectors and amplifiers. In these arrangements, the vacuum tube contained not only the two electrodes of the Edison tube, but also contained a third element—a grid of spaced wires—placed in the vacuous space in the tube between the hot filament and the plate. The heated filament and plate of the tube were

here connected with a *direct current* battery circuit, having its negative end permanently connected to the filament and its positive end permanently connected to the plate, and thus tending to produce a flow of current through the tube at all times. The operation of the device depended on the discovery that by changing the potential of the grid, the flow of electrons from the always negatively charged filament (cathode) to the always positively charged plate (anode) could be controlled. In the detector arrangement, the translating device (the headphone) was placed in the local battery circuit, and the incoming alternating current signal was connected through a grid condenser to the grid in the tube, so that the audio-components of the received oscillations would so polarize the grid relative to the filament as alternately to retard and accelerate the flow of the larger battery current between filament and plate (Finding LXXV; 1 R. 69). In the amplifier arrangement, an alternating current of audio-frequency was applied to the grid to control the increase or decrease of a larger current in the battery circuit (Finding LXXVI; 1 R. 72).

The court below found that insofar as defendant's structures and the invention disclosed in the Fleming patent had anything in common, the common matter had been disclosed in the earlier Edison patent and was well known to the art

before the earliest date to be accorded the Fleming patent; that the art was familiar with the ability of the Edison tube to rectify alternating currents; that the Fleming patent, to one skilled in the art, included only the use of the well-known "Edison effect" to rectify alternating currents of radio frequencies; that the defendant's manner of using the "Edison effect" differed in means for applying it, mode of operation, and result, from that of Fleming (Findings LXV–LXXX; I R. 62–74); and that defendant's structures therefore did not infringe the Fleming patent (Finding 1; I R. 116–117).[3]

Although the ultimate findings of fact on which the judgment relating to the Fleming patent is based (I R. 60–74) were restricted to the issue of infringement (I R. 75), and did not include matters relating to validity, the court made evidentiary findings relating to the prior art and to the disclaimer; and in its opinion the court below held that the Fleming patent was invalid because of unreasonable delay in filing the disclaimer (I R. 105–107).[4] The court further indicated, without

[3] Findings identified by arabic numerals refer to those made by the court below after the accounting proceedings, in connection with the final judgment of April 6, 1942; roman numerals refer to findings made before such proceedings, in connection with the interlocutory judgment of November 4, 1935.

[4] The court found that the disclaimer was filed long after the three-electrode tube had been invented and employed in radio apparatus as a detector, amplifier and oscillator, and

deciding, that the patent may also be invalid because the alleged new use Fleming made of the "Edison effect" lacked invention (I R. 104–105).

SUMMARY OF ARGUMENT

I

The court below properly held that the Marconi patent No. 763,772, as to all claims in suit except claim 16, was invalid because anticipated in the prior art. The alleged improvement in the field of wireless communication, which the patent purported to disclose as of November 10, 1900, consisted in adjusting the inductance and capacity of either the two circuits at the transmitter or the two circuits at the receiver, or all four of these circuits, in order to tune them to the same frequency or wave length. All these features had already been shown in the art, as the court below properly found. Hertz between 1879 and 1890 had established the basic principles of tuning the transmitting and receiving circuits of a wireless system to the same frequency in order to sustain the maximum response. Lodge in 1894 fully explained Hertz' teachings in terms of a wireless communication system, and Marconi in an 1897 patent showed receiving apparatus which could be electrically tuned to oscillations from a transmitter.

---

after the United States had used substantial quantities of three electrode tubes as detectors and amplifiers (Findings LXV, LXXI; I R. 62, 74).

Then Tesla in 1897 showed (as Marconi's patent in suit showed in 1900) a wireless transmitter system containing a charging circuit for causing oscillations of a desired frequency, an antenna circuit for transmitting these oscillations, coupled to the charging circuit through a transformer, and the synchronizing or tuning of these two circuits by adjusting the inductance of the circuits. Tesla, moreover, disclosed the same arrangement in the receiver, and thus anticipated the four circuit tuning combination of Marconi.

The only feature in Marconi's arrangement which was absent from Tesla's was the use of a more readily variable inductance in the antenna circuit as the tuning medium of the transmitter, but this very feature, used for the same purpose, was found in Lodge's disclosure of 1898, almost three years prior to Marconi. Hence, the court below properly held that Tesla, read in conjunction with Lodge, anticipated all of Marconi's claims for four-circuit tuning. It might properly have found that Lodge alone anticipated all the receiver claims. Similarly, the 1899 patent of Marconi, antedating the one in suit, brought out the principle of tuning the circuits of transmitter and receiver by variable inductance coils, in accordance with the varying wave lengths. Finally, before Marconi's date of November 10, 1900, Stone disclosed on February 8, 1900 (and even earlier in his letters to Baker) the

tuning of all four of the open and closed circuits of transmitter and receiver to the same frequency. While Stone did not prescribe the particular means for adjusting the frequency of the aerials, he did prescribe tuning them to the desired fundamental frequency; and the art was familiar at that time with the use of a variable inductance for such purpose.

Prior litigation upholding the Marconi patent is of no authority on the question of validity since in two of the cases the Stone defense was not before the court and in the third the patent was held not infringed, rendering unnecessary any opinion as to invalidity. Moreover, none of the prior cases considered specifically whether there was any invention in using the Lodge tuning coil to effect the tuning of Tesla's apparatus.

II

An additional ground for affirmance of the judgment for defendant, urged but not passed on below, is that the evidentiary findings made by the court and the record upon which they are based establish that defendant's apparatus did not infringe the Marconi patent. No criteria of infringement are available under the decision below since all claims of the Marconi patent (except claim 16, not here involved) were held invalid. But the conclusion must be against infringement even if, as the criteria, there be taken

features judicially upheld in two decisions of lower federal courts (*Marconi Wireless Telegraph Co.* v. *National Electric Signaling Co.*, 213 Fed. 815 (E. D. N. Y.) and *Same* v. *Kilbourne & Clark Mfg. Co.*, 239 Fed. 328 (W. D. Wash.) affirmed 265 Fed. 644 (C. C. A. 9)), and in a decision of an English court concerning the corresponding British patent (*Marconi* v. *British Radio Telegraph & Telephone Co.*, 27 T. L. R. 274). The feature held novel in these cases was the use in the transmitter of a persistently oscillating charging circuit employing a low resistance plain spark gap, with loose coupling between that circuit and an antenna circuit in exact tune therewith. With this arrangement the charging circuit fed only a small part of its energy to the antenna circuit on each oscillation, so that the radiation of the antenna circuit would be continually replenished on each oscillation and thus be prolonged. The courts in question distinguished this arrangement from the prior art transmitter of the Lodge patent, which used tight coupling and a more highly resistant, and less persistent oscillator circuit, whereby the latter would deliver its energy to the antenna in a rush and then cease operating, to leave the antenna circuit free to oscillate at its own natural period and rate of damping.

The defendant's quenched gap transmitters, constituting most of the transmitter apparatus

alleged to infringe, do not employ the distinctive structure, mode of operation, and result held to differentiate Marconi's system from Lodge, but instead follow Lodge's principles, using a high-resistance quenched gap in a charging circuit tightly coupled to a somewhat detuned antenna circuit—features which prevent the charging circuit from being a persistent oscillator, and give both the charging and antenna circuit a mode of operation like that of Lodge and different from that of Marconi's arrangement. The commercial displacement of the plain gap transmitters by the quenched gap type soon after their development further attest to their substantial dissimilarity. On principle and authority and in view of the prior art, these transmitters did not infringe Marconi's alleged invention.

Defendant's rotary gap transmitters were similar to the quenched gap type, also quenching the spark quickly and preventing the charging circuit from being a persistent oscillator; these transmitters did not infringe for the reasons stated with respect to the quenched gap transmitters. And the few plain gap transmitters used by the defendant did not trespass upon Marconi's patent because defendant's apparatus had direct instead of transformer coupling between the charging and antenna circuits, and there is no evidence that they were loosely coupled or that they attained Marconi's slow feeding operation and result.

Defendant's receivers also do not infringe the Marconi patent. The features of Marconi's system upheld by the three courts referred to above were attributable solely to Marconi's transmitter, and not to his receivers, *per se;* and to the extent that any matters disclosed by Marconi are to be found in defendant's receivers, they are equally to be found in the prior art.

III

The court below properly found that the Fleming patent No. 803,684 was not infringed, and did not pass upon the defense of invalidity urged by defendant. However, the court's evidentiary findings as to the prior art, and as to the structure, operation, and effect of Fleming's device—which were required in order to enunciate the proper criteria for gauging the alleged infringement—necessarily lead to a conclusion of invalidity.[49] The Fleming patent disclosed a two-electrode vacuum tube, one electrode of which was heated, with a circuit connecting the two electrodes outside the tube. A direct current indicator in this circuit responded when an alternating current was impressed on the circuit and rectified by the one-way conductivity of the tube. The incoming alternating current signal was received in an antenna circuit and was impressed on the single external circuit of the tube by a transformer.

---

[49] As to the order of argument, see n. 49, p. 105, *infra.*

Every element of this arrangement, and this combination, was to be found in the prior art. Edison in 1884 received a patent on the very two-element tube shown by Fleming as of November 16, 1904, containing a heated filament and a colder plate, connected together outside the tube. The rectifying operation of the Edison tube upon alternating currents, due to the unidirectional flow of current between filament and plate, was recognized and published by Fleming in 1890, more than ten years before his patent application; it was also described and illustrated by others in 1897. In 1903, the deValbreuze patent employed a similar two-electrode tube in an identical circuit to rectify alternating currents of high or Hertzian wave frequency, and Wehnelt in October 1904—a month before Fleming's earliest date—also disclosed the specific arrangement described in Fleming's patent to rectify alternating currents. The art prior to Fleming, in discussing the rectifying operation of the Edison tube, properly had drawn no distinction between rectifying high frequency and low frequency alternating currents; and to those skilled in the art it was implicit in the known operation of the device, that it would rectify low or high (Hertzian) frequencies of alternating current with equal facility. The specific disclosure of the prior art de Valbreuze patent applying a like two-electrode tube as a rectifying

detector of wireless waves, in the same circuit proposed by Fleming, disposes of any contrary contention. The Fleming patent was thus invalid for anticipation and lack of invention.

Additional reasons exist for invalidity of the Fleming patent. Plaintiff disclaimed from the scope of that patent all use of the device to rectify low-frequency currents, but did so more than ten years after it had been held out to the public as dominating rectification of high and low frequencies. Indeed, whatever the frequencies, the arrangement operated without change in but one manner, to produce but one result, rectification. The patent when issued, on its face squarely covered subject matter which Fleming knew had entered the public domain years before. The disclaimer thus was unreasonably delayed. Moreover, the subject matter of the disclaimer was improper, for it either did not disclaim any properly separable part of the patent, or it attempted to add a new element to the invalid claims—the requirement that the current rectified be of radio frequency.

IV

The finding of the court below that the Fleming patent No. 803,684 was not infringed by the De-Forest three-electrode tube employed by defendant, is sustained by evidentiary findings which are in turn supported by substantial evidence. The Fleming patent employed the Edison two-electrode

tube as a rectifier of alternating current introduced into its single external circuit to enable that very current, when rectified, to operate an indicator in that circuit. DeForest's three-electrode tube, on the contrary, employed only the large direct current of a local battery in its plate circuit to operate the indicator. This current needed no rectification. DeForest added a new discovery to the Edison tube, nowhere suggested by Fleming, namely, that by placing a third element, a grid, in the evacuated space between the filament and plate, it would be possible to impart to the tube a new mode of operation, relay action, enabling one to produce large changes in the local battery current of the plate circuit by impressing small potential changes on the grid.

As the incoming energy acted in the grid circuit to control a local current in the entirely separate plate circuit, the device was a relay. As it produced the proportionately large changes in the current of the plate circuit, compared to the changes of potential on the grid, the device was an amplifier. Thus its structure, mode of operation and result were different from those of the Fleming device.

Further, the three-electrode tube served to reproduce, as variations in the local plate current, changes of potential, however derived, applied to the grid. In defendant's amplifiers, the changes of potential were derived from an alternating

current of low or audio-frequency (excluded from the Fleming patent by disclaimer). In one form of defendant's detector, the grid was given a basic negative charge by a small battery in the grid circuit so that it would permit only a small current to flow in the plate circuit. Alternating current applied to the grid then rendered it alternately more positive and negative than its basic charge, reproducing by relay action the modulation of the incoming alternating current by allowing large increases and causing only small decreases in the plate current. These plate current variations, when averaged up by an indicator, caused the indicator to respond to the reproduced modulation. In the other form of detector, a grid condenser bridged by a high resistance leak was employed in lieu of the grid-biasing battery. This arrangement caused the grid to assume a negative charge proportional to the modulation (amplitude) of the incoming signal and thus, by relay action, to reproduce, in variation of the local direct current in the plate circuit, a replica of the intelligence transmitting characteristic of the signal, suitable to operate the indicator.

The ability of the three-electrode tube to amplify enables it to be used as an oscillator or self-sustained generator of oscillations for use in a transmitter; and plaintiff now concedes that the two-electrode valve, as disclosed by Fleming, cannot either amplify or oscillate. Oscillation in

the triode is effected by using a little of the current variation in the plate circuit to effect changes in potential of the grid which in turn produce larger variations in the plate current, until a maximum variation of plate current results; and this continues as a steady oscillation continuously replenished by amplification through the tube. That portion of the steady oscillation not being "feedback" to maintain the tube in oscillation may then be delivered to a transmitting antenna circuit coupled directly, or through a transformer, to the plate circuit of the oscillating tube circuit, for radiation thereby. The regenerative receivers employed the same "feed-back" principle, but feed-back only enough energy to reenforce an incoming signal applied to the grid, and not enough to sustain the tube in oscillation.

Thus the Fleming patent used the two element tube theretofore shown by Edison, in an already known alternating current rectifying circuit containing a direct current indicator, to *rectify* the received alternating currents of Hertzian frequencies, so that the rectified energy of those received currents could operate the direct-current indicator in the alternating-current circuit. Defendant's three-electrode tubes employed a different structure (a three-element tube) operating in a different way (by relay action) to produce a different result (an amplified reproduction in a large local direct current of a replica of voltage variations impressed on the grid).

The substantial dissimilarity between defendant's and Fleming's devices is further shown by the rapidity with which the triode replaced the older form of tube, and the signal contributions which the triode made to the art. The only case which held the Fleming patent valid and infringed by DeForest's triode is *Marconi Wireless Telegraph Co. of America* v. *DeForest Radio Telephone & Telegraph Co.*, 236 Fed. 942 (E. D. N. Y.), affirmed 243 Fed. 551 (C. C. A. 2). That decision is entitled to little weight on either of these issues, for both parties had there agreed, for collateral reasons, that the two-electrode and three-electrode vacuum tubes were essentially alike, thus eliminating any controversy on the matter crucial to the decision here.

ARGUMENT

The judgment entered below holding Marconi patent No. 763,772 invalid and Fleming patent No. 803,684 not infringed can be challenged only by showing that the findings of fact lack substantial evidence to support them or that the ultimate findings of fact are not sustained by the evidentiary findings of fact. We believe that plaintiff has not and cannot make any such showing. But even if the court below were in error in holding the Marconi patent invalid and the Fleming patent not infringed, we submit that the judgment should be affirmed because it is adequately sustained by additional grounds, which were urged

but not passed on by the court below. More particularly, we submit that the Marconi patent, even if valid, was not infringed by the defendant's transmitters because these differed substantially from Marconi's arrangement in structure, mode of operation and result. Likewise, the Fleming patent, whether or not infringed, was in our view invalid because anticipated, at least as to the features alleged to have been infringed, by prior disclosures. In any event, Fleming's patent was invalid because the 1915 disclaimer of the device as applied to low frequency currents was made after unreasonable delay and was not in its substance within the disclaimer statutes. The evidentiary findings made below will sustain the judgment in defendant's favor upon these alternative grounds; and such alternative grounds, having been urged below, may be considered by this Court. *Stelos Co.* v. *Hosiery Motor-Mend Corp.*, 295 U. S. 237.

PART ONE: MARCONI PATENT NO. 763,772

POINT I

THE COURT BELOW PROPERLY HELD MARCONI PATENT NO. 763,772 INVALID BECAUSE ANTICIPATED IN THE PRIOR ART

The court below found that Marconi patent No. 763,772, as to all claims in suit except claim 16, was anticipated by the prior disclosures of Tesla, Lodge and Stone, and by an earlier patent to Mar-

coni himself. This conclusion is supported by adequate evidentiary findings of fact, which are in turn grounded upon substantial evidence.

1. *The Disclosures of Marconi Patent No. 763,772*

Marconi patent No. 763,772 was granted on June 28, 1904. Its stated object was "to increase the efficiency" of wireless telegraph transmitting and receiving systems, and

> to provide new and simple means whereby oscillations or electric waves from a transmitting station may be localized when desired at any one selected receiving station or stations out of a group of several receiving stations (Ex. 21, p. 1, lines 13–19; IV R. 2588).

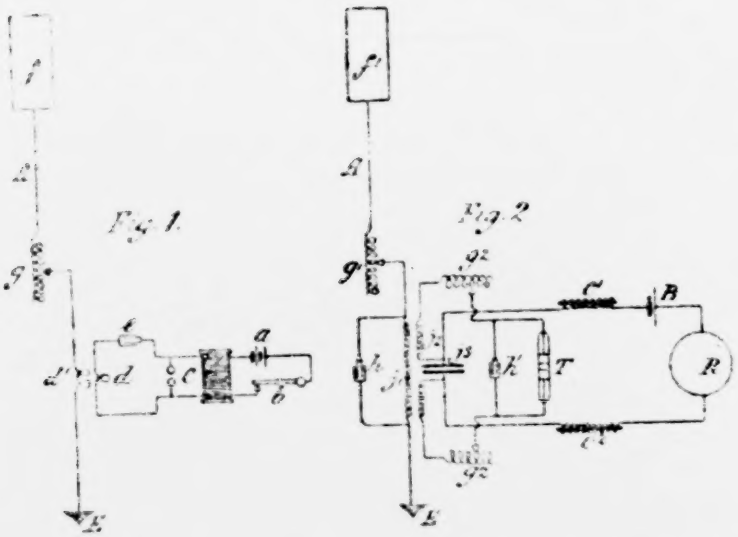
The means employed by Marconi to carry out his invention are illustrated as follows in Figures 1 and 2 of his patent:

(a) The Transmitter: Claims 1, 3, 6, 8, 11, and 12

At the transmitting station (Fig. 1), the patent specification (IV R. 2591) calls for

(i) an oscillation transformer *d d'* "of a kind suitable for the transformation of very rapidly alternating currents" (lines 36–38),

(ii) "one coil of said transformer" *d'* "being connected between the aerial wire or plate" *f* "and the connection thereof to earth" *E*,



(iii) "while the other coil of the transformer" *d* "is connected in circuit with a condenser" *e* (lines 39–43), and forms part of

(iv) a persistent oscillator, which further comprises "a producer of Hertzian oscillations or electric waves shown in the form of a spark producer" (i. e., the low-resistance plain spark gap, adjacent to the letter *c*) "and an induction coil (*c*) controlled by a signaling instrument" *b* (lines 43–46), and

(v) a good radiator (i. e., the open antenna circuit, *f A E*).

The specification explains that the battery *a*, through the induction coil *c*, charges the condenser *e* until the voltage thereof is sufficiently high to break down the resistance of the spark gap (adjacent to the letter *c*), whereupon the current leaps the gap and completes the primary

circuit, *e d* and gap, creating high frequency oscillations therein. This circuit, sometimes referred to as the charging circuit, constitutes the "persistent oscillator" of the patent.[1] The spark gap is shown as a "plain gap", i. e., one of relatively low resistance which allows the oscillations to persist in the charging circuit, *e d* and gap, for some time before being damped out by the resistance of the circuit. The circuit is tuned to the desired frequency of transmission by the inductance (the coil *d*) and capacity (the condenser *e*) in the circuit; hence, the oscillations in the charging circuit will persist for a maximum period of time commensurate with their transfer to the antenna circuit before the spark gap ceases to be conductive. As long as the oscillations persist in the charging circuit they will induce correspondingly prolonged oscillations in the antenna *A* to which the charging circuit is coupled by the oscillation transformer *d d'*. The persistency of the oscillations is aided, and their

[1] The patent specification states (IV R. 2392, lines 12–24):

"My experiments have demonstrated that the best results are obtained at the transmitting station when I use a persistent oscillator—an electrical circuit of such a character that if electromotive force is suddenly applied to it and the current then cut off electrical oscillations are set up in the circuit which persist or are maintained for a long time—in the primary circuit, and use a good radiator—i. e., an electrical circuit which very quickly imparts the energy of electrical oscillations to the surrounding ether in the form of waves—in the secondary circuit."

gradual transfer from the charging circuit to the antenna or radiating circuit is effectuated, by "loosely" coupling the circuits so that only a small portion of the energy of each oscillation in the charging circuit is transferred to the antenna circuit on each alternation of the current. This "loose-coupling" is effectuated by the presence in the antenna circuit of the relatively large inductance *g*, which, not being coupled to the charging circuit, acts to delay (i. e., "swamp" or "bog down") the influx of energy from the charging circuit into the antenna circuit, thus permitting the remainder of the energy to persist as oscillations in the charging circuit.*

The principal features of Marconi's transmitter are thus

> i. means for adjusting the charging and antenna circuits to the same frequency by a variable capacity (*c*) in the charging circuit and a variable inductance (*g*) in the antenna circuit, and

---

* When the circuits of an oscillation transformer (such as *d d'* in Marconi's Fig. 1) are coupled tightly, as by the coils being close together or wholly overlapping each other without other provisions for loosening the coupling between the circuits, the reaction of the currents in the circuits produces resonance to waves of two frequencies (known to the art as a "double hump") in the resonance characteristic of the antenna at the transmitter or of the detector circuit at the receiver. This reduces the power applied in generating the desired frequency, and reduces the persistency of oscillation (II R 900-905; Ex. M-2, Loftin Sketch F; V R. 3590).

> ii. means for making the oscillations in the charging circuit persistent, that is, the low resistance plain spark gap and the loose coupling between the circuits produced by the "swamping" action of the inductance *g*.

Of the claims in suit, claims 1, 3, 6, 8, 11, and 12 relate to the transmitting station. They cover both the charging circuit and the antenna circuit, and provide either for a "variable inductance included in the open circuit" (claims 1, 3, 8, and 12) or "an inductance" (claim 11) or a "means for adjusting the oscillation period of each of the two circuits" (claim 6).

(b) The Receiver: Claims 2, 13, 14, 17, 18, and 19

At the receiving station (Figure 2), the patent specification calls for an oscillation transformer *j' j''*

> one coil whereof is included between the aerial receiving-wire and earth, constituting a good absorber of electrical oscillations, while a device responsive to electric waves, such as an imperfect contact or a device for operating the same, is included in a circuit with the other coil of said transformer (p. 1, lines 49–56).

The receiver consists of a receiving circuit *f' A g' h j' E*, and a detector circuit $j'' g'' h'$—*T* j^3 containing a wave responsive device *T*, with variable inductances *g'* and g'' for adjusting the two circuits to the same frequency. Of the claims in

suit, claims 2, 13, 14, 17, 18, and 19 deal with the receiving station.[9] They cover both the antenna circuit and the detector circuit, and provide for a wave-responsive device in the detector circuit together with "means for adjusting the two transformer circuits" (claims 14 and 17), or for a variable inductance in the antenna circuit (claims 2, 13, 17, 18, and 19).

(c) Tuning: Claims 10 and 20

An essential element of Marconi's system is the tuning of the two circuits at the transmitter and of the two circuits at the receiver to the same frequencies, so that all four circuits will be in electrical resonance with each other. The specification first prescribes tuning the two circuits at each station (p. 1, lines 56–62), and particularly states (this having been added by amendment, IV R. 3955–3967, 3968):

> The system also requires as essential elements thereof the inclusion in the lines (at both stations) from the aerial conductor to the earth of variable inductances and the use at both stations of means for varying or adjusting the inductances of the two circuits at each station to accord with each other.

[9] Claim 16, which also relates to the receiving station, is dealt with in the *United States* v. *Marconi Wireless Telegraph Company of America*, this Term, No. 373.

It then provides for tuning all four circuits (p. 2, lines 118–129):

> The capacity and self-induction of the four circuits—i. e., the primary and secondary circuits at the transmitting-station and the primary and secondary circuits at any one of the receiving-stations in a communicating system—are each and all to be so independently adjusted as to make the product of the self-induction multiplied by the capacity the same in each case or multiples of each other—that is to say, the electrical time periods of the four circuits are to be the same or octaves of each other.

The variable elements e g g' g^2 constitute the means whereby all four circuits can be adjusted to the same frequency. Claim 10 specifies that the two circuits at each station shall be in electrical resonance with each other, and claim 20 recites that there shall be "means" for bringing the four transformer circuits, two at each station, into electrical resonance with each other.

2. *Wireless Development Prior to the Marconi Patent*

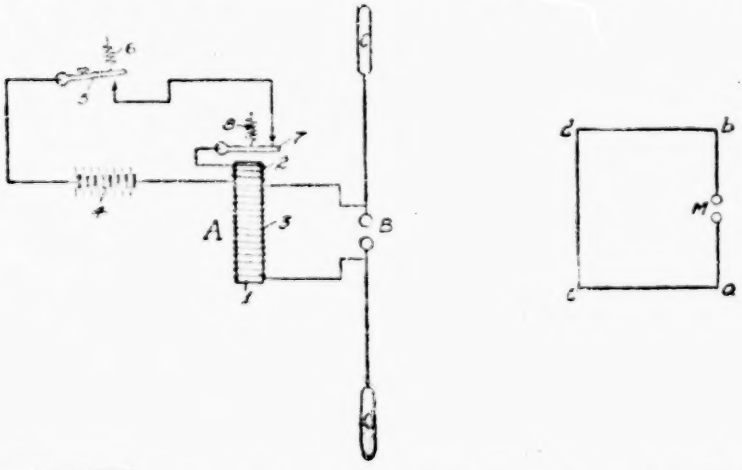
A brief summary of the early development of wireless telegraphy will facilitate a comparison between Marconi's alleged invention in suit and the prior art which the court below found anticipated Marconi.

(a) Hertz' Teachings

Clerk Maxwell at an early date disclosed the theory of wireless telegraphy, and his statements of fundamental laws still serve as the foundation of wireless communication (II R. 858). Maxwell, however, did not reveal any apparatus for utilizing his theory; it was Heinrich Hertz, between 1879 and 1890, who first evolved and demonstrated apparatus for carrying the Maxwellian theory into effect (II R. 869, 872, 873). One form of apparatus used by Hertz and described in a publication of September 21, 1888, was as follows (transmitter on the left, receiver on the right):[10]

(i) *Hertz' Transmitter*

Referring to the transmitter (left), A represented an induction coil (or Ruhmkorff coil),



[10] Hertz' work was described by De Tunzelmann in 1888 in a series of articles published in the *London Electrician* (Ex. F-2, bound in reversed order at V R. 3566–3589).

which was already a well-known device. It consisted of an iron core *1*, upon which were wound a primary coil *2*, consisting of relatively few turns of heavy wire, and a secondary coil *3*, consisting of a large number of turns of fine wire, so that an alternating or pulsating current in the primary coil would induce a current of much higher voltage in the secondary coil. The primary circuit of the induction coil consisted of the primary coil *2*, a battery *4*, a circuit breaker *5*, normally held in open position by a spring *6*, and another circuit breaker or "trembler" *7*, normally held closed by a spring *8*, but adapted to be opened by the attraction of core *1* when energized by current in the closed primary circuit. The secondary circuit of the induction coil (the charging circuit for the antenna) comprised the secondary coil *3*, the spark gap or discharger *B*, and the plates or capacity areas *C C*. These capacity areas *C C*, being connected to the spark gap *B*, imparted capacity to this charging circuit and also, with the spark gap *B*, formed the antenna or radiating circuit.

The operation of this transmitter was as follows: Upon closing switch *5*, battery *4* would energize coil *2*, magnetizing core *1* and causing it to attract switch *7*; such attraction would then open the primary circuit and thus demagnetize the core *1*, permitting switch *7* again to close (through its spring *8*) and start the energization

of coil 2, to resume the entire process. As long as switch 5 was held closed, switch 7 was thus caused to "tremble", i. e., to make and break its circuit. The constant making and breaking of the primary circuit induced in the core a rising and falling magnetism which in turn induced an alternating current in the secondary coil 3. The voltage of the current in the latter coil, however, was higher than that in the primary coil 2, in the same proportion that the number of turns of wire in the secondary coil bore to the number of turns of wire in the primary coil.

By connecting the secondary coil to the spark gap or discharger *B*, the voltage built up in the knobs or terminals of the gap would ionize the air between them until the insulating effect broke down, causing a spark to leap across the gap from knob to knob. So long as the switch 5 was closed, a succession of sparks was caused to pass across the gap of the discharger, and during the continuation of each spark, a high-frequency oscillation of current occurred in the circuit *C B C*, consisting of several "swings" or impulses steadily decreasing in amplitude. As long as the primary circuit was closed there would occur a succession of these group oscillations.

By connecting the spark gap to the plates *C C* in the antenna circuit, which had a large area, capacity areas were provided for receiving a large charge of current from the induction coil,

thus increasing the power of the transmitting system. The frequency or wave length to which a circuit resonates or vibrates (the "fundamental" of the circuit), and thus the wave length of the oscillations it can generate, is determined by the circuit's inductance (length and disposition of the straight or coiled-up wire in the circuit) and capacity (area of and distance separating charged metal surfaces in the circuit, as the plates *C C*). Consequently, the additional capacity areas *C C*, as Hertz recognized (see n. 12, p. 34, *infra*), changed one of the two components determining the frequency of the oscillations in the circuit and thus constituted a means modifying or adjusting the frequency of its oscillations. This was one of the first principles in tuning.

(ii) *Hertz' Receiver*

Hertz' receiver comprised a loop or ring of wire, shown in the form of a rectangle half a meter in length, the ends being connected to the knobs of a spark gap or micrometer *M*. In the apparatus illustrated above (p. 30), the terminal conductors of the transmitter, *C* and *C*, "were three meters apart" while the receiver or "micrometer circuit" consisted of a "rectangle 80 centimeters broad by 120 centimeters long" (Ex. F–2; V R. 3585).

These measurements are significant in demonstrating Hertz' awareness of the principles of

tuning or synchronization, for the dimensions of Hertz' receiving circuit (the inductance) were so chosen, and the spacing of his micrometer knobs *M* (determining the capacity between them) was intentionally so adjusted as to render the circuit resonant to the wave length of his transmitter.[11]

There is thus no doubt that the principles of resonance, so universally employed in all wireless apparatus, were understood and applied by Hertz in determining the constants for his receiver (i. e., the length of wire and the micrometer dimensions) and that he selected those constants which would cause his receiver to resonate to the transmitted wave length.[12]

---

[11] This is revealed in Hertz' own detailed description of his apparatus (Ex. J 4; V R. 3891) and was recognized by Lodge (see p. 36, *infra*).

[12] De Tunzelmann recognized this in 1888. He wrote that in order to determine whether "the oscillations were of the nature of a regular vibration," Hertz "availed himself of the principle of resonance," according to which "an oscillatory current of definite period would, other conditions being the same, exert a much greater inductive effect upon one [i. e., a receiving circuit] of equal period than upon one differing even slightly from it.

"If, then, two circuits are taken having as nearly as possible equal vibration periods, the effect of one upon the other will be diminished by altering either the capacity or the coefficient of self-induction of one of them, as a change in either of them would alter the period of vibration of the circuit." (V R. 3585.)

Prof. Ebert also recognized in 1894 that the Hertz receiver was "electrically tuned" to resonance, and that he used "tuned circles of wire." (V R. 3888.)

(iii) *Lodge's Observations on Hertz' Teachings*

After about six years, during which the work of Hertz attracted wide attention, Sir Oliver Lodge in 1894 published a series of articles in the *London Electrician*[13] describing and explaining Hertz' teachings by diagrams corresponding to those now in common use. In an article of June 8, 1894, he explained the elementary principles in precisely the way they are explained today:

> Conversely, if the source is a persistent vibrator, correct tuning is essential, or it will destroy at one moment motion which it originated the previous moment. Whereas, if it is a dead-beat or strongly damped exciter, almost anything will respond equally well or equally ill to it. * * *
>
> Furthermore, any conductor electrically charged or discharged with sufficient suddenness must emit electrical waves into the ether, because the charge given to it will not settle down instantly, but will surge to and fro several times first, and these surgings or electric oscillations must, according to Maxwell, start waves in the ether, because at the end of each half swing they cause electrostatic, and at the middle of each half swing they cause electromagnetic effects, and the rapid al-

[13] This series of articles, June 8 to July 20, 1894, is in evidence as Exhibit E–4. (V R. 3872.)

ternating from one of these modes of energy to the other constitutes etherial waves.

Maxwell and his followers well knew that there would be such waves; they knew the rate at which they would go, they knew that they would go slower in glass and water than in air, they knew that they would curl around sharp edges, that they would be partly absorbed but mainly reflected by conductors, that if turned back upon themselves they would produce the phenomena of stationary waves, or interference, or nodes or loops; it was known how to calculate the length of such waves, and even how to produce them of any required or predetermined wave length from 1,000 miles to a foot. * * *

Electric syntony.—That was his [Hertz'] discovery, but he did not stop there. He at once proceeded to apply his discovery to the verification of what had already been predicted about the waves, and by laborious and difficult interference experiments he ascertained that the previously calculated length of the waves was thoroughly borne out by fact. These interference experiments in free space are his greatest achievement. (V R. 3873–3874.)

The range of wave lengths given by Lodge—from one foot to 1,000 miles—includes the entire range of what are sometimes called radio frequen-

cies and a very large part of the range of the so-called audio-frequencies.[9]

The Lodge papers also pointed out that several different types of detecting device could be employed in the receiving circuit to detect or ascertain the existence of the transmitted wave: spark gaps, telephones, vacuum tubes, galvanometers and even a pair of frog's legs used by Hertz and Ritter. (V R. 3876–7.)

(iv) *Summary of Hertz' Disclosures*

Thus from the work of Hertz the art was informed that by applying to a spark gap current of a voltage sufficiently high to break down the gap and to send the current across it, an oscillating electrical discharge of high frequency (now known as "Hertzian waves") would be caused in

[9] Wave lengths are expressed today in terms of meters, or more commonly in terms of cycles or frequency. A wave length of 1,000 miles is the same as one of 1,584,000 meters, or 186 cycles per second—an extremely long wave length. A wave length of one foot is the same as a wave length of three-tenths of a meter or 982,080,000 cycles per second—an extremely short wave length.

The ordinary human ear can hear sound wave frequencies ranging from 16 cycles up to about 10,000 cycles per second; some extremely sensitive ears may hear such frequencies as high as 30,000 cycles. The range of radio frequencies may be said to be from 30,000 cycles per second up to 1,500,000 cycles per second (I R. 311). There is no fixed dividing line between radio frequencies and audio-frequencies (i. e., those corresponding to the frequencies of audible soud waves) but as a sound frequency rises above 6,000 cycles per second it begins to become inaudible to human ears.

the spark gap or charging circuit and would be communicated to the antenna circuit; that these high frequency waves would propagate ether waves of the same frequency, which could be intercepted by a receiving circuit at a distance; that either mechanical detectors or vacuum tubes could be employed as detector devices in the receiving circuit; that by tuning the antenna and the receiving circuits to the same frequency the maximum response would be obtained; and that the plain gap circuit was a "persistent vibrator."

Hertz did not discover the principles of resonance; they were already well known. He did, however, appreciate from the beginning that in view of the minute values of the energy utilized in the receiving apparatus, tuning to resonance would be essential to almost all practical apparatus, in order that the transmitted waves might be effectively received.

The basic soundness of the Hertz disclosures, and their faithful embodiment in most wireless systems, were judicially recognized in 1905. *Marconi Wireless Telegraph Co. of America* v. *DeForest Radio Telephone & Telegraph Co.*, 138 Fed. 657 (C. C. S. D. N. Y.).[15]

[15] The court there said: "The means for the later development of wireless telegraphy were furnished in the proof by actual experiment of the correctness of certain theories promulgated by Prof. Maxwell, of Cambridge, in 1865, that electricity, like light, traversed space through the medium of ether, and that, if a spark be created by a disruptive dis-

(b) Marconi Prior Patent No. 586,193

Marconi in a patent antedating by seven years the one here involved also recognized the principles of resonance, and tuned the antenna circuit of his receiver to accord with the antenna circuit of the transmitter. This prior patent No. 586,193, covering Marconi's earliest invention, was granted July 13, 1897, upon an application filed December 7, 1896, and was reissued as Reissue patent No. 11,913 on June 4, 1901 (Ex. 19, IV R. 2567). It disclosed the following transmitter (Fig. 10) and receiver (Fig. 11), both substantially like Hertz' apparatus:

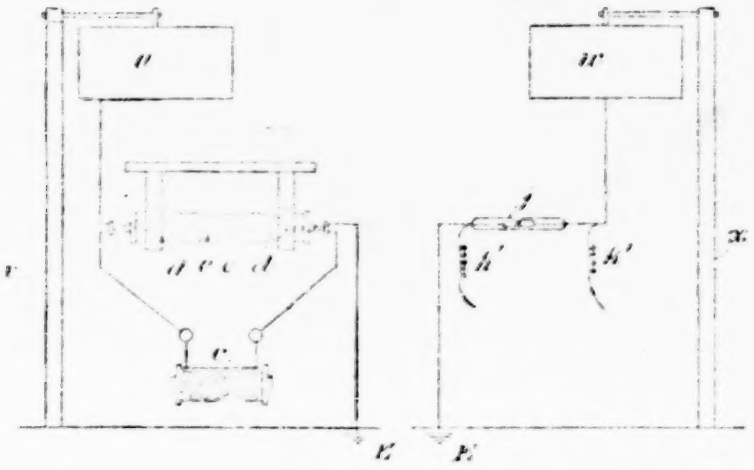
At the transmitting station (Fig. 10), the 1897 Marconi patent showed a Ruhmkorff coil c^{10} which

charge, it will spread out in waves or undulations. These waves are known as 'Hertz waves' or 'Hertz oscillations,' from the name of their discoverer, Heinrich Hertz. He produced these waves by the use of an apparatus consisting of a radiator and a receiver equipped with rods having small metallic knobs on the ends, and separated a short distance from each other. This separation is the spark-gap, by means of which the Hertzian waves or oscillations are produced. When the transmitter or radiator is connected with a Ruhmkorff coil, or any source of high electric tension, such as an induction coil, with mechanical vibrator, or a producer of electric current, such as a dynamo, a charge of electricity is sent through the circuit which includes the spark-gap, and a spark passes across the spark-gap and creates the electrical vibration or wave called the 'Hertz wave'" (p. 658).

[10] This coil, as shown in Fig. 1 of the patent (IV R. 2569) was the usual Ruhmkorff coil shown in the illustration on p. 30, *supra*, and had the customary key in its primary or battery circuit.

delivers a high tension, high frequency current to the spark gap, *d c c d* in the secondary circuit of the coil. One side of the spark gap is grounded at *E* and the other side connected to an elevated wire and plate *a* insulated from the earth on the pole *v*.

Fig. 10. Fig. 11.



At the receiving station (Fig. 11), a coherer *j* is inserted in the antenna circuit *w E* as the detector device. The coherer, a tube containing a rather coarse metallic powder, normally prevents flow of current in the local battery circuit (connected to choke coils *h' h'* but not shown in Fig. 11), but as soon as an impulse is received by the antenna circuit the metallic particles are caused to cohere,

so as to provide a conductive path closing the battery circuit, thereby causing a signal. Choke coils *k' k'* are provided to keep high frequency waves out of the local battery circuit. A relay in the battery circuit operates a stronger battery circuit containing a sounder and a trembler for tapping the coherer so that its circuit will be broken after the incoming waves have ceased (Ex. 19; Findings IX and X, I R. 12, 13). Metal plates are used for tuning, "preferably of such a length as to be electrically tuned with the electric oscillations transmitted" (Ex. 19, p. 3, lines 28–30; IV R. 2574).

In this Marconi patent the apparatus is substantially the same as that disclosed by Hertz, with the following exceptions: (i) Hertz, unlike Marconi, did not employ the earth as one of the capacity areas of his transmitter or use similar capacity areas at the receiver, and (ii) Marconi, unlike Hertz, used a coherer as the detector device in his receiver.

3. *Prior Art Anticipating Marconi's Patent No. 763,772*

Following the development in the art discussed above, came disclosures which the court below found anticipated Marconi's patent here involved.

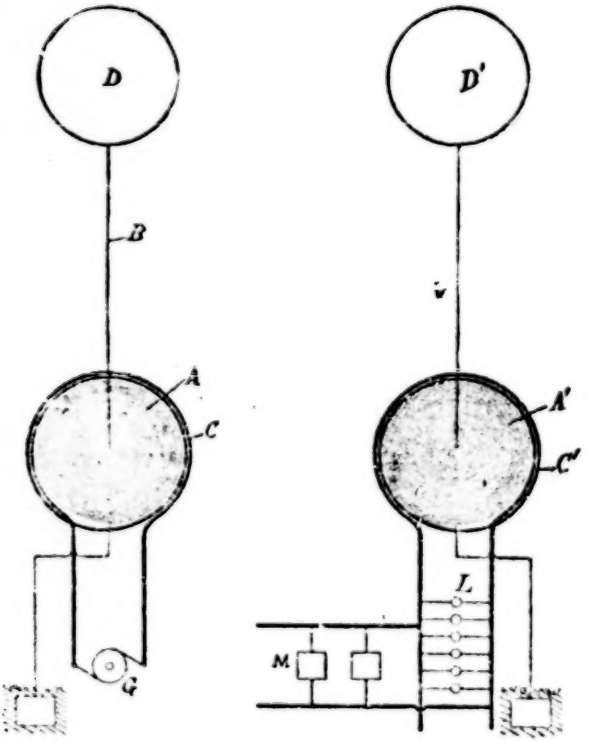
The art thus held to invalidate the Marconi patent consisted of prior inventions by Tesla, Lodge, Stone and Marconi himself. These disclosures antedated the earliest date which Marconi is entitled to claim for his alleged invention in patent No. 763,772—viz., November 10, 1900, the filing date of his application (Finding XLI, I R. 37). Consequently, the propriety of the conclusion below that the prior art invalidated Marconi's patent depends upon whether the anticipating disclosures and Marconi's device were substantially the same in structure, mode of operation and effect. We submit that such substantial similarity was properly found to exist.

(a) Tesla Patent No. 645,576

Tesla patent No. 645,576, granted March 20, 1900 upon an application filed September 2, 1897, disclosed two circuits (one open and one closed) at both the transmitter and the receiver, and provided for synchronizing or tuning these circuits together. The following apparatus was shown in the Tesla patent (Ex. X–2, V R. 3602):

In the transmitter (left-hand figure), high frequency oscillations are delivered from the source *G* to the primary coil *C* of an oscillation transformer.[1] The secondary coil *A* of the oscillation

[1] The source *G*, "one of the elements of the transmitter," is described in the Tesla patent as "a condenser of a capacity of about four one-hundredths of a microfarad * * * charged from a generator of alternating currents of fifty



transformer, which has many more turns than the primary coil *C*, is connected at one end to earth and at the other end to an aerial *B D*. Thus the primary or charging circuit automatically causes oscillations of the desired frequency and delivers them to the open or antenna circuit, from whence they are radiated into space.

In the receiver (right-hand figure), a similar transformer is employed, except that it is the

---

thousand volts' pressure and discharged by means of a mechanically-operated break five thousand times per second through the primary *C*'" (Ex. X–2, p. 3, lines 117–125, V R. 3605.)

primary coil *A'* which is of thin wire and which has more turns than the other, the secondary coil *C'*. Tesla contemplated primarily the transmission of waves sufficiently powerful to operate motors and the like, for in the secondary circuit he included lamps *L*, motors *M* "or other devices for utilizing the current" (Ex. X–2, p. 3, lines 24–26; V R. 3605). However, he also recognized that this method of energy transmission, without change of apparatus, could be used for wireless communication (p. 5, lines 28–35; V R. 3607):

> The apparatus which I have shown will obviously have many other valuable uses—as, for instance, when it is desired to transmit intelligible messages to great distances * * *.

Since the transmission of intelligible messages to great distances involved no change of apparatus disclosed, and was merely dependent upon the use of the usual key to interrupt the power supplied through the source *G* at the transmitter, Tesla clearly disclosed to those skilled in the wireless telegraphy art an open aerial circuit coupled to a closed charging circuit at the transmitter, and an open aerial circuit coupled to a closed detector or receiving circuit at the receiver.

Moreover, as the court below properly found (Finding LXXII, I R. 58), Tesla instructed those skilled in the art that the open and closed circuits of the transmitting system and the open and

closed circuits of the receiving system should be in resonance with each other; in other words, that all four circuits should be in resonance. The Tesla patent states that the "primary and secondary circuits in the transmitting apparatus" are "carefully synchronized", this synchronism being attained—

> When the primary coil or system A', with its secondary C'', was carefully adjusted, so as to vibrate in synchronism with the transmitting coil or system AC. (Ex. X–2, p. 4, lines 27–29; V R. 3696).[*]

Thus, Tesla concentrated most of his inductance in the form of coils in his antenna circuits, and adjusted this inductance by adjusting those coils, so tuning his circuits. Indeed, in 1899 Stone recognized "four-circuit" tuning as Tesla's contribution (see p. 69 and note 28, *infra*).

---

[*] Tesla's teaching in this respect is further set forth in his prior art patent No. 649,621 granted May 15, 1900, upon a division of the application for patent No. 645,576, wherein he says (Ex. L–6, p. 1, line 97 to p. 2, line 10; V R. 4090, 4091):

"It will be readily understood that when the above-described relations exist the best conditions for resonance between the transmitting and receiving circuits are attained, and owing to the fact that the points of highest potential in the coils or conductors A A' are coincident with the elevated terminals the maximum flow of current will take place in the two coils, and this, further, necessarily implies that the capacity and inductance in each of the circuits have such values as to secure the most perfect condition of synchronism with the impressed oscillations."

It is thus clear that Tesla disclosed and anticipated the following features of the Marconi patent: (i) a charging circuit in the transmitter for causing oscillations of a desired frequency, (ii) an aerial or antenna circuit in the transmitter coupled through a transformer to the charging circuit for transmitting these oscillations, and (iii) the synchronizing of these two circuits by adjusting the inductance in the antenna circuit. Moreover, by disclosing the same arrangement in the receiver, Tesla anticipated the four-circuit tuning combination of Marconi.

The only feature in Marconi's arrangement which was absent from Tesla's—the use of a "variable inductance" in the antenna circuit of the transmitter and receiver as the tuning medium—was found in the Lodge disclosure prior to Marconi, as we shall show.

(b) Lodge Patent No. 609,154

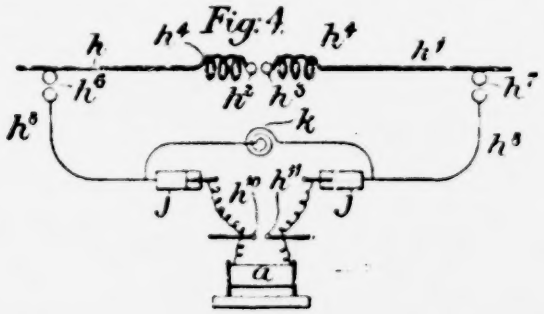
In patent No. 609,154, granted August 16, 1898, upon application filed February 1, 1898 (Ex. 20, IV R. 2581), Sir Oliver Lodge disclosed, prior to Marconi, a variable inductance coil in a wireless transmitter or receiver to enable them to be tuned together. The finding of the court below to this effect (Finding XXIX, I R. 26) is clearly sustained by substantial evidence.

Lodge's patent provided for a self-inductance coil *h* ' between a pair of capacity areas *h* and *h'*

(which, he disclosed, may be antenna and earth respectively) in an oscillating circuit of either a sending or receiving set (or both) for Hertzian wave telegraphy. The patent disclosed that such coil should be made adjustable at will to vary the value of its self-inductance. Lodge explained that the adjustment, that is, "the desired frequency of vibration or syntony with a particular distant station," may be attained by a coil itself capable of adjustment, or

> by replacing one coil by another, for the frequency can be adjusted either by varying the capacity of the condenser or jar or other conductor employed or the charged body on the one hand or by varying the number and position of coils or other portion of the discharge-circuit on the other (Ex. 20; IV R. 2585, lines 39–48).

The transmitter was illustrated as follows in Figure 4 of the patent:



As decribed in the specification, the transmitter contained three or four spark gaps (h^{10}–h^{13}, h^{a}, h^{c}, and optionally h^{d}–h^{f}), instead of the usual single

spark gap. The effect of this was to cut off quickly the arc of energy in the charging circuit, and, with the aid of tight coupling between the open and closed circuits, to transfer the energy quickly from the closed to the open circuit," i. e., in "an impulsive rush." (Ex. 20; IV R. 2584, lines 72-75).

The Marconi patent, claims 1 and 3, describe the open circuit of the transmitter simply as "electrically connected with" the charging circuit, and as containing a variable inductance. These Marconi claims do not require an oscillation transformer in the transmitter, nor the tuning of the open and closed circuits; consequently, as the court below properly found (Findings LXI; I R. 57), they read directly upon the auto-transformer arrangement in Figure 4 of the Lodge patent and are anticipated.[*]

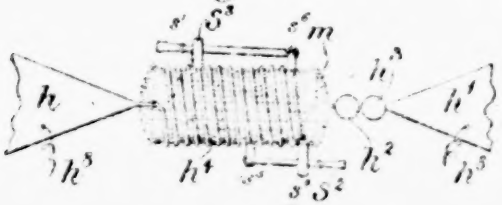
As the court below found, the Lodge patent also described and claimed a variably acting self-inductance coil in a transmitter or receiver, to enable the transmitter and the receiver to be tuned together (Finding XXIX; I R. 26). The adjustable inductance of the Lodge patent is set

[*] All of the inductance h^1 h^4 is common to the charging circuit and the antenna circuit, hence the coupling between the two oscillatory circuits is tight. When two circuits are each connected to include a common coil, the coil is called an "auto-transformer."

[*] The similarity between the two devices is plainly to be seen from a comparison of Figure 1 of the Marconi patent (*supra*, p. 24) with Loftin's simplified sketch of Lodge's Figure 4 (*infra*, p. 50).

forth in Figure 9 of his specification (following), in which the switches s' s^2 are so related to the inductance coil h' as to short-circuit any desired number of turns of the coil to adjust its effective inductance and thus tune the circuit.

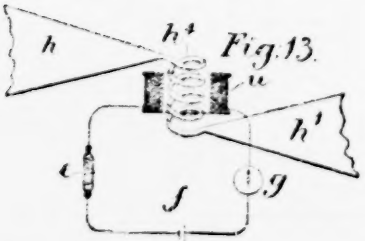
Fig. 9.



The two forms of receiver in the Lodge patent are shown in Figures 12 and 13:

Fig. 12.

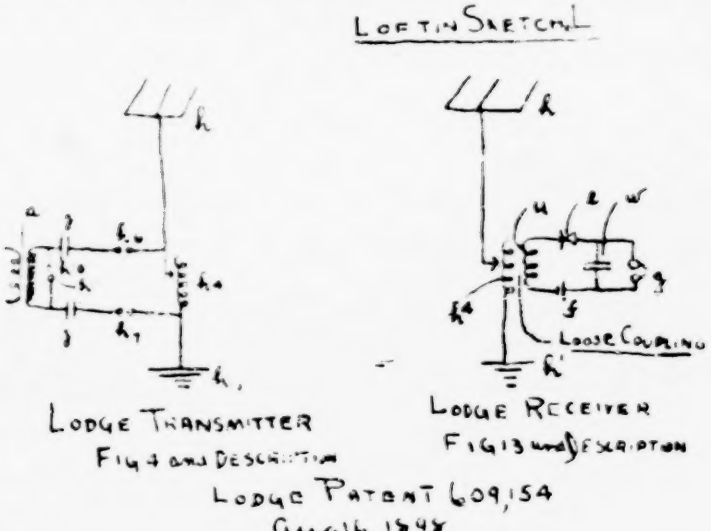
Fig. 13.



In Figure 12, the detector circuit e f g is directly coupled to the terminals of the inductance coil h' in the antenna circuit; in Figure 13, the two circuits are inductively coupled through a

transformer having the primary coil h^4 in the antenna circuit and the secondary coil u in the detector circuit. The element w in Figure 12 is either a resistance or a capacity (IV R. 2586, line 65), which may be used across the instrument g, i. e. in circuit with coherer c in Figure 13 (IV R. 2586, line 62).

The following simplified sketch submitted by defendant's witness Loftin presents, in the conventional diagrammatic form, the Lodge transmitter of Figure 4 and the Lodge receiver of Figure 13, with antenna and earth as the capacity areas, as previously taught by Marconi in patent No. 586,193 (pp. 39–40, *supra*),[a] and as contemplated by Lodge (Ex. 20, IV R. 2584, line 37 and lines 103–107; and Figs. 6 and 7, IV R. 2581):



[a] Ex. V-2, IV R. 3600. Loftin fully explained this sketch and the operation of Lodge Fig. 4 at II R. 946–952.

The only feature in Marconi which was not shown in Tesla's system was the use of a variable inductance in the antenna circuit of the transmitter as the tuning medium to vary its periodicity, instead of accomplishing the same result by selection of a proper fixed inductance. But, as shown above, this more convenient mode of effecting the tuning specified by Tesla was shown by Lodge before the earliest date attributable to Marconi. Since Lodge's variable inductance was the only feature which Marconi combined with Tesla's system of tuning the two transmitter circuits to the same frequency, the court below correctly held (I R. 98) that Tesla, read in conjunction with Lodge, anticipated all of Marconi's claims for four-circuit tuning.[22]

Indeed, the court might properly have found that Lodge alone fully anticipated the receiver

[22] The court below made evidentiary findings of fact explaining the structure and mode of operation of Tesla's disclosure of four-circuit tuning (Finding LXII, I R. 58-59) and of Lodge's showing of a variable inductance coil as an instrumentality for effecting tuning (Finding XXIII, I R. 23). It also made evidentiary findings as to the structure and operation of Marconi's four-circuit tuning (Findings XXXVIII, XLIII, XLVII; I R. 31-40, 42). While it made no "findings" labeled as such, that Tesla and Lodge anticipated particular claims of Marconi, such "findings" are mere conclusions readily to be drawn from a simple comparison of the appropriate evidentiary findings, and are in any event implicit in the ultimate finding made by the court as to invalidity of the Marconi patent, as its opinion in fact reveals (I R. 97-99).

claims of Marconi's patent here involved. These claims (2, 13, 14, 17, 18, and 19) were directed to the combination of an oscillation receiving conductor (the antenna circuit), a wave responsive device electrically connected with the conductor (the detector circuit), and a variable inductance in the antenna circuit (claims 2, 13, and 18), or "means for adjusting the two transformer circuits in electrical resonance with each other" (claims 14 and 17). As the court below found (Findings LIX and LXI, I R. 57), none of these claims actually require that the two circuits shall be in resonance with each other; they require only that there shall be means for making the adjustment, the means shown being an adjustable inductance in the antenna circuit. Lodge's patent alone, as shown above, fully disclosed the use of the variable inductance coil for tuning the antenna circuit; consequently, no invention was involved in Marconi's employing the Lodge variable inductance for adjusting the circuits in lieu of making the adjustment by varying the length of the wire or the size of fixed coils, especially since no new function was imparted thereby either to the circuits or to the variable inductance.[*] Merely making known elements ad-

[*] The court below also found (Finding LXI, I R. 57) that claim 2 of Marconi's receiver group was the same in structure and operation as Figure 13 of the Lodge patent, and

justable, when no new or unexpected result is attained thereby, is not invention, particularly when the prior art shows such adjustability to be known in the same or analogous uses, *Peters* v. *Hanson*, 129 U. S. 541, 550–551.

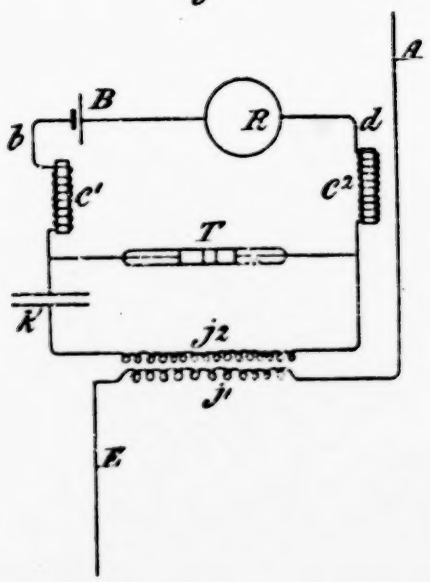
(c) Prior Art Marconi Patent No. 627,650

As the court below found (Finding LII, I R. 46), the principle of tuning the respective circuits of the receiver (and transmitter) by varying inductance coils to accord with the varying wave lengths, was also brought out in the prior art Marconi patent No. 627,650, granted June 27, 1899, upon an application filed January 5, 1899 (Ex. P–5, same as Ex. B–6, V R. 4085–8). The receiver described in this patent was illustrated in Figure 1 as follows:

---

hence anticipated by it. This is fully sustained by the evidence. Marconi's claim 2 is not limited to the tuning of the open and closed circuits, nor to a variable inductance used in addition to the transformer primary coil. Lodge's Figure 13, with condenser *w* of Lodge's Figure 12 connected in circuit with coherer *e* as described by Lodge (p. 50, *supra*), satisfied every requirement of Marconi's claim 2. Indeed, that claim does not even require an oscillation transformer, and is thus directly applicable to Figure 12 of Lodge as well.

Fig. 1.



In it, Marconi employed a coupling transformer j' j^2 which he referred to as an "induction coil," the antenna or aerial conductor A being connected to the primary winding j' of the "induction coil" and thence grounded to earth E. The secondary winding j^2 of the coil was in the detector circuit, and a coherer T (described as an "imperfect contact") was connected to the ends of the secondary winding of the coil, through a variable condenser k' (id., V R. 4087, lines 14–20). The specification recited that:

> It is desirable that the induction-coil should be in tune or syntony with the electrical oscillation transmitted, the most appropriate number of turns and most appro-

> priate thickness of wire varying with the length of wave of the oscillation transmitted.
>
> The capacity of the condenser on the connection between the imperfect contact and the secondary of the coil should be varied (in order to obtain best effects) if the length of wave is varied. (id., lines 31–42).

As was pointed out by defendant's expert witness Loftin (II R. 951), these are clear directions to tune the respective circuits, by means of the variable inductance in the antenna circuit and the variable condenser in the detector circuit. The apparently contrary statement of plaintiff's expert witness Weagant that varying the condenser *k'* would be "totally incapable of tuning the receiving circuit" (II R. 1627) is the result of a confusion between the effect of resistance and the effect of inductance and capacity. *Resistance*, it is true, does not affect the tune or frequency of the circuit, and merely affects the amplitude of the wave, whatever its frequency. But it is clear that changing the *capacity* does affect the tune. This was brought out by Marconi himself, who in effect contradicted Weagant's testimony as follows (I R. 539):

> How do you tune a coherer circuit?
>
> A. We tune it by proportioning the inductance and the capacity of the circuit

> in which it is, so that that circuit will be in tune with the oscillations which you want to receive.

The tuning of the two receiver circuits by using a variable inductance in the antenna circuit was the subject matter of claims 2, 13, 18, and 19 of Marconi's patent in suit (see pp. 27–28, *supra*). Since Marconi's earlier patent in 1899 disclosed such tuning by the use of an "induction coil" containing "the most appropriate number of turns" and by the use of a variable condenser in the secondary winding of that coil, the finding of the court below that Marconi's earlier patent anticipated claims 2, 13, 18, and 19 in suit is fully sustained by substantial evidence.

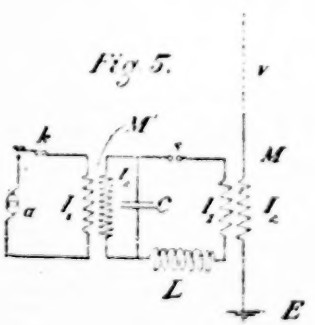
(d) Stone Patent No. 714,756

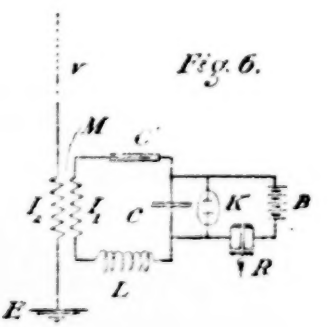
(i) *Stone's Disclosures*

Also before the earliest date for Marconi's alleged invention (November 10, 1900) John Stone Stone clearly disclosed the tuning of the aerial circuits of wireless apparatus by inductance, and the tuning of the open and closed circuits of the transmitter and receiver, all four to the same frequency. This disclosure was made by Stone in a patent application filed February 8, 1900, upon which patent No. 714,756 was granted on December 2, 1902 (Ex. P–3, V R. 3648.) While Stone did not describe the partic-

ular means for adjusting the frequency of the aerial, he did prescribe adjusting the value of the inductance to the desired frequency, and to one skilled in the art this meant the use of a variable inductance, such as had previously been disclosed by Lodge patent No. 609,154, for example (Finding LVII, I R. 56).

Stone's patent explained in great detail the effect of one circuit upon another, and showed that in a *single* tuned circuit there is a "single degree of freedom," i. e., one natural period in which the current oscillates with freedom, whereas if *two* such circuits are coupled together, there will result a system of "two degrees of freedom," i. e., the super-position of two frequencies. Stone then described the following transmitter (Figure 5) and receiver (Figure 6):





The transmitter (Fig. 5) had a telegraph key *k* in the primary winding I'_1 of an induction coil *M'*. In the secondary winding I'_2 of this induction coil there was a spark gap *s* which generated high-frequency oscillations through the closed cir-

cuit s C L I_1. This circuit was electrically connected, through an oscillation transformer M, with an open or antenna oscillating circuit r I_2 E.

The receiver (Fig. 6) comprised an open oscillating circuit r I_2 E, inductively coupled through the transformer M with a closed oscillating circuit I_1 C' C L. A coherer or wave-responsive device K was connected across the condenser C.

In his specification, Stone disclosed two systems of four-circuit tuning, one of which the court below held anticipated Marconi. In that system Stone disclosed tuning the open and closed circuits at the transmitter and receiver, all to the same frequency or wave length.[5] For this purpose, at the transmitter he adjusted the charging circuit (C s I_1 L) to the desired frequency, and preferably adjusted the antenna circuit to be resonant to the same frequency, thus tuning the two transmitter circuits to the desired wave length: at the receiver he tuned the antenna circuit to the incoming frequency, and tuned the detector circuit to the antenna circuit. This is to be seen

[5] For the other system, a multiplex arrangement, Stone proposed employing two tuned circuits at the transmitter and two at the receiver, all tuned to the same wave length, those at the transmitter forcing the selected wave length on an aperiodic antenna circuit, and those at the receiver receiving the selected wave length from an aperiodic antenna circuit. The aperiodic antennas used in this form of Stone's system were ones capable of radiating or absorbing any one of a number of wave lengths in the range of wave lengths to be employed. Figures 13, 14, 16 and 17 of the Stone patent relate to this system.

from the following statements in his specification referring to the transmitter:

> Thus the frequency impressed upon the elevated conductor may or may not be the same as the natural period or fundamental of such conductor (Ex. P–3; V R. 3648, lines 16–20).
>
> The vertical wire may with advantage be so constructed as to be highly resonant to a particular frequency, and the harmonic vibrations impressed thereon may with advantage be of that frequency (Ex. P–3; V R. 3653, lines 62–66).

And with respect to the receivers:

> When the apparatus at a particular station is attuned to the same periodicity as that of the electromagnetic waves emanating from a particular transmitting-station, then this receiving-station will respond to and be capable of selectively receiving messages from that particular transmitting-station to the exclusion of messages simultaneously or otherwise sent from other transmitting-stations in the neighborhood which generate electromagnetic waves of different periodicities. Moreover, by my invention the operator at the transmitting or receiving station may at will adjust the apparatus at his command in such a way as to place himself in communication with any one of a number of stations in the neighborhood by bringing his apparatus into resonance with the periodicity em-

ployed by the station with which intercommunication is desired (Ex. P–3; V R. 3651, lines 17–36).

Indeed, further to insure that only the one desired fundamental frequency would be transferred at the transmitter from the charging circuit to the antenna circuit, and at the receiver from the antenna circuit to the detector circuit, Stone proposed that another closed circuit be interposed between the closed (charging or detecting) circuit and the open (antenna) circuit of transmitter and receiver, as shown in Figures 7 and 8, respectively, of his patent:

Fig. 7

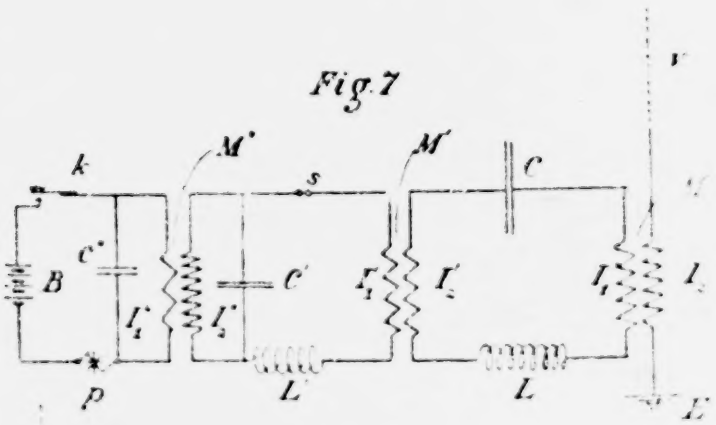


Fig. 8.

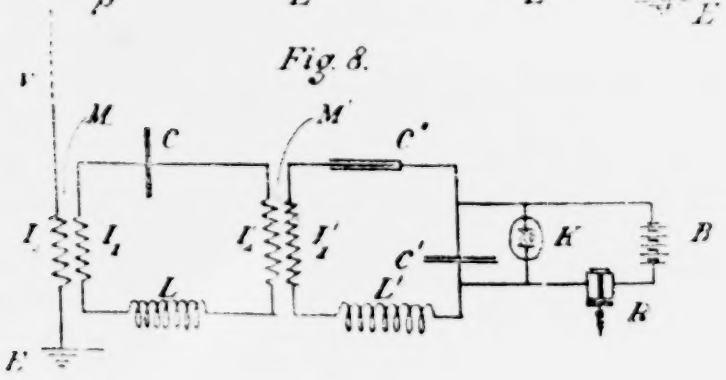

In respect of the transmitter (Figure 7), the specification states:

> In the transmitter arrangements illustrated in Figure 7 the circuit $C I'_2 L I_3$ is attuned to the same period as the circuit $C'' L' I'_3 s$ and merely tends to weed out and thereby screen the vertical wire from any harmonics which may exist in the current developed in the circuit $C'' L' I'_3 s$ (Ex. P–3; V R. 3653, lines 89–94).

And in respect of the receiver (Figure 8), the specification states:

> In the organization illustrated in Figure 8 the electric resonator $C I'_2 L I_3$, interposed between the vertical conductor and the circuit containing the coherer is attuned to the same period as the circuit $L' C'' C''' I'_1$ and acts to screen the coherer-circuit from the effect of all currents developed in the vertical conductor, save that of the current of the particular period to which the receiving-station is intended to respond (*id.*, lines 122–131).

The Stone disclosures thus fully support the finding below that Stone tuned the closed circuit of his receiver and transmitter "to the frequency of the transmitted signal," and that from his suggestion to tune the open transmitter circuit "it was obvious to one skilled in the art that the receiver open circuit should also be tuned." Indeed, as the court further found, Lodge among others had earlier disclosed the desirability of

such tuning and the manner of accomplishing it (see pp. 47–48, *supra*), and the disclosure and first claim of Stone's application as filed had suggested it.[25] In short, "to one skilled in the art, Stone's patent contemplated having all four oscillating circuits in tune or accord with each other" (Findings LIII and LVII; I R. 47, 50, 56–57).

The court recognized that the Stone patent drawing made no attempt to show adjusting of the condensers or inductances in any of the oscillating circuits, but found that "one skilled in the art at the time knew how to adjust any or all of them to obtain the desired resonance in the open and closed circuits." (Finding LIII, I R. 47, 50). This finding is equally supported by the evidence. Lodge, among others, had informed the art how to adjust the inductances (see p. 49, *supra*) and easily adjustable condensers were also well known at this time, having been shown by Marconi himself in a prior patent (pp. 54–55, *supra*) and by Tesla in 1894 (Ex. B-4; V R. 3839, 3840–3841). Consequently, the Stone patent was correctly found to anticipate Marconi with respect to adjustable four-circuit tuning.

Plaintiff attacks the Stone defense, asserting that the description of tuning the open antenna

---

[25] The specification as filed also shows clearly Stone's understanding that any coupled circuits would be tuned to resonance in obtaining the single frequency by his loose coupling arrangement. (V R. 3653, lines 98–102; see also footnote 26, p. 64, *infra*.)

circuits was inserted in the Stone application by amendment in April 1902, after Marconi's application was filed on November 10, 1900. This contention is in effect that the 1902 amendment of Stone's application departed from the original disclosure and for the first time introduced the matter of tuning the antenna circuits. But the record completely disproves this.

In claims 1, 3, and 4 of his application as originally filed, Stone claimed producing the same wave length or frequency in both circuits (Ex. R-3; V R. 3685, 3708). His original specification explained that the antenna or vertical conductor "is made the source of electromagnetic waves of but a single periodicity" (V R. 3697), and directed that the closed circuit should be tuned to the desired frequency, that the closed and antenna circuits should be "loosely" coupled, and that the coupling between these circuits should be adjusted to impart the desired single frequency to the antenna circuit (V R. 3697–9). These directions necessarily amounted to a disclosure that the antenna currents of both transmitter and receiver would be of the same frequency.[27] Moreover, Stone's original specification had made clear that if but one frequency was to be transmitted, the apparatus would correspond to a tuning fork (V R. 3698), whereas when the elevated conductor was aperiodic several fre-

[27] I R. 770, last two paragraphs, and particularly last three lines. (See also footnote 26, p. 64, *infra*.)

quencies would be transmitted. This in effect was a statement that the elevated conductor was *not* aperiodic when only one frequency was to be transmitted.[29] The subject of the 1902 amendment, which merely explained these matters in more detail, was thus plainly found in the original disclosure. Indeed, if plaintiff's contention had any foundation, it would have been the duty of the Patent Office examiner to have refused the 1902 amendment, as containing matter not shown, described or suggested in the original specification.[30] The absence of any indication in the record that the examiner had the slightest difficulty in allowing the amendment, coupled with the presumption that public officers have properly performed their duties,[31] require the conclusion that the tuning of the antenna circuits had been sufficiently disclosed in the original application to be apparent to the examiner as one skilled in the art at the time.[32]

---

[32] When a "single frequency" is to be attained by loosely coupled circuits, the circuits *must* be attuned to the same natural period (I R. 770).

But even if the disclosure of tuning the open circuits had not been complete in the original application and had been supplemented by the 1902 amendment, it would not deprive Stone of priority. For the record shows that long before Marconi's date Stone had conceived four-circuit tuning (including tuning of the antenna circuits as previously taught by Lodge); that Stone had recorded this conception and disclosed it to others as early as June and July 1899; and that during the intervening period Stone was diligent in reducing the invention to practice and in obtaining capital to exploit his invention.

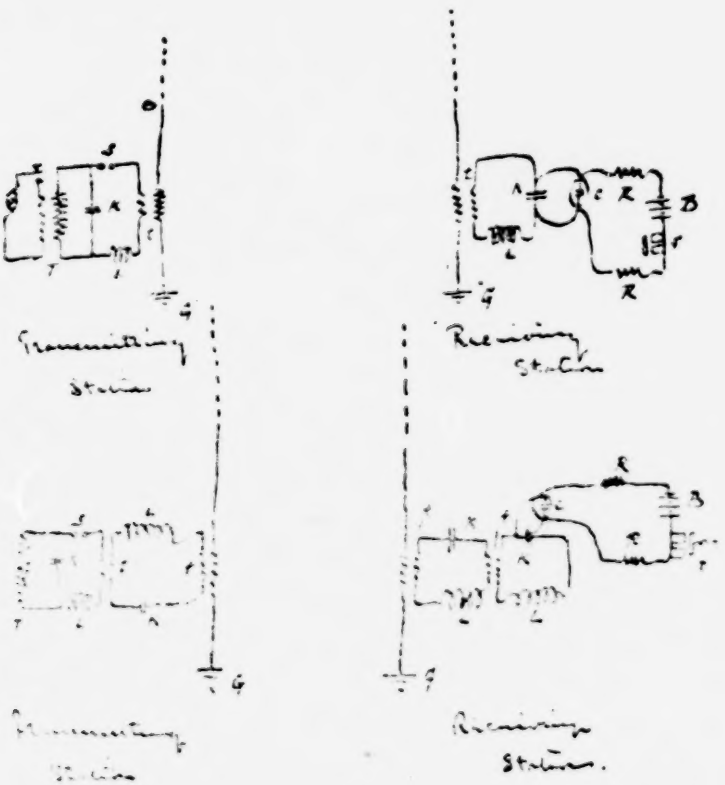
(a) *Stone's Disclosures Prior to His Patent Application*

In the summer of 1899, Stone disclosed his four-circuit tuning system to his friend, Mr. J. B. Baker, who was also skilled in the art, and who corroborated the disclosure (I R. 735, 738, 739). Stone's letter of June 30, 1899, to Baker, reads in part as follows:

> Instead of utilizing the vertical wire itself at the transmitting station as the oscillator, I propose to impress upon this vertical wire, oscillations from an oscillator, which oscillations shall be of a frequency corresponding to the fundamental of the wire. Similarly, at the receiving station, I shall draw from the vertical wire, only that component of the complex wave which is of lowest frequency.
>
> If now the fundamental of the wire at the receiving station be the same as that

of the wire at the transmitting station, then the receiving station may receive signals from the transmitting station, but if it be different from that of the transmitting it may not receive those signals.

* * * * *



In these sketches, G is ground, K is condenser, C is coherer, L is inductance coil without iron, T is step-up transformer, t is transformer without iron, R is retardation coil, B is battery, r is relay.

The tuning of these circuits one to another and all to the same frequency will probably be best accomplished empirically.

though the best general proportions may be determined mathematically (Ex. F–3, V R. 3631–3633).

In the first paragraph quoted above, Stone clearly showed that at the transmitter he would not put the spark gap in the vertical wire of the antenna circuit, as had Marconi's 1897 patent (see pp. 39–40, *supra*), but instead would put it in a separate oscillator or charging circuit adjusted to generate oscillations of the same frequency or wave length as that of the antenna circuit, and then transfer these oscillations to the antenna circuit. In his sketches he showed this transfer to be accomplished by a coupling transformer *t*.

Plaintiff attempts to construe the arrangement disclosed in the above letter as limited to "forced" oscillations, because of the phrase "I propose to impress," etc. Plaintiff argues that this letter consequently makes no disclosure of the transfer of oscillations through inductive coupling of resonant circuits, the method used by Marconi and the defendant (Pl. Brief, pp. 35–36). This argument, based upon a mere play on words, is untenable.[*] Any limitation of Stone's disclosure to

[*] If Stone had used the words "I propose to induce in the vertical wire," he might have limited his concept to transformer coupling, which was the specific mode of transfer shown by Tesla (see pp. 42–46, *supra*), and in Stone's diagrams, reproduced above. The use of the broader term "impress upon," to distinguish his method from the prior manner of generating the oscillations directly in the antenna circuit, indicates an intention to embrace generically the idea

"forced" oscillations is impossible in view of the context of the letter and more particularly the statements (1) that the oscillator circuit frequency would be made to correspond to the fundamental of the antenna circuit, (2) that the fundamental of the vertical aerial wire at the receiver should be the same as that of the aerial wire at the transmitter, and (3) that the several circuits would be tuned "one to another and all to the same frequency" (Ex. F–3; V R. 3631, 3633).

Since in the letter of June 30, 1899, Stone clearly disclosed, prior to Marconi, a transmitter having a charging or spark gap circuit and an antenna circuit coupled together by a transformer, a receiver having an antenna circuit and a detector circuit coupled together by a transformer, the two circuits at each station being tuned to one another, and all four circuits being tuned to the same frequency, this letter alone would be sufficient evidence to support the finding below (Finding LIV, LVIII; I R. 51, 57) that Stone anticipated this concept of Marconi's patent. But there is further supporting evidence.

---

of transfer. That other than transformer coupling could be used is borne out by the fact that at the time of the letter Hertz's direct coupling was well known (p. 30, *supra*, and Lodge had already filed his application for patent showing such transfer accomplished by autotransformer coupling (see Lodge figs. 4 and 12, pp. 47 and 49, *supra*). See also I R. 762. Stone's careful choice of broad language was to be expected, for the letters to Baker were written for the purpose of making a record (I R. 739).

On July 18, 1899, Stone again wrote to Baker (Ex. G-3; V R. 3634), explaining and mathematically demonstrating how to achieve the "single" frequency. He pointed out that if the fundamental of the vertical wire (antenna) is of the same period (or frequency) as the oscillator circuit in the transmitter, the "*current*" in the vertical wire will be greater. Significantly, Stone himself observed in this letter that the tuning of the four circuits to the same frequency, which he had disclosed to Baker in the letter of June 30, "is practically the same as that employed by Tesla" (see pp. 42–46, *supra*), except that by the use of the large inductance coil *L* Stone "swamped" the reactions from the coil of the oscillating transformer. The "swamping inductance" *L* reduced the coupling between the open and closed circuits of the transmitter,[28] and

[28] The letter of July 18, 1899, from Stone to Baker is in part as follows:

"The current in the vertical wire in my system may therefore be represented by a simple harmonic

$$A_2 \sin 2 pt$$

and if the period of the impressed force be the same as that of the fundamental of the vertical wire then it may be represented by

$$A_1 \sin pt$$

"*The radiations will also be simple harmonic and of the same periodicity p* and will develop in the vertical wire at the receiving station a corresponding simple harmonic electromotive force *of periodicity p.*

"I space the coherer at the receiving station in a resonant circuit tuned to the periodicity p.

* * * * * *

(Continued at bottom of p. 70.)

slowed down the transfer of energy from the plain gap charging circuit to the antenna circuit, thus permitting the former to oscillate more persistently.

These letters were acknowledged by Baker in a letter of July 22, 1899, to Stone, reading in part (Ex E–3; V R. 3629):

> The "selective" methods of space telegraphy therein described I believe I understand sufficiently to set up and operate them.
>
> Allow me to add that this speculation of the work which Marconi's experiments to date leave in rather primitive condition is

---

"The first transmitting circuit shown in my letter to you of June 30 is practically the same as that employed by Tesla for the production of high frequency currents, except that I place an inductance coil *L* in the circuit to give additional means of tuning and to swamp by its greater inductance the reactions from the induction coil *t*, which would tend to make the oscillations multi-periodical instead of simple harmonic. The induction of this coil should be made large compared with the inductance of the primary of *t*.

* * * * *

"At the receiving station the coil *L* and condenser *k* form a resonant circuit which is attuned to the frequency of the current developed at the transmitting station.

"Again the inductance of the coil *L* should be made larger compared to the inductance of the secondary of the induction coil *I* at the receiving station in order to obtain well defined resonance to a single frequency."

The mode of operation of this "swamping inductance" to reduce the coupling between the circuits is explained in detail by defendant's expert Loftin at II R. 977, in connection with Ex. M-2, Loftin Sketch F; V R. 3590. See Brief for the United States in No. 373, this Term, pp. 20, 21, notes 19 and 20.

very important and should be prosecuted without delay by way of further development and protection by letters-patent.

Besides being the prior inventor in this respect, Stone showed diligence in adapting and perfecting his invention. He disclosed his invention to several persons in addition to Baker, and in January 1900 described the invention to his class at the Massachusetts Institute of Technology (I R. 760, 765, 1120, 1123). Further, during this and the succeeding period he was diligent in obtaining capital to form the Stone Wireless Syndicate (I R. 760) and in reducing the invention to actual practice (I R. 762), and he filed his application for patent on February 8, 1900, still prior to Marconi's earliest date (I R. 37). Thereafter, the Stone Telegraph & Telephone Company was organized in December 1901 (I R. 821), and it built wireless stations and sold apparatus, equipped a Navy collier and some battleships, and applied for a large number of patents (I R. 762–763, 822).

The character of apparatus used in the stations is described by Stone (I R. 766–767) as comprising, at both the transmitter and the receiver, resonant open and closed circuits loosely coupled inductively with each other, and all tuned to the same wave length in accordance with the Stone system as set forth in the Baker letters, the Stone patent No. 714,756, and the Stone M. I. T. lectures (I R. 765–766). All of these were prior to the earliest date established for the Marconi

invention, and although some of the stations built by the Stone Company continued up to 1909 or 1910 (I R. 822), the Company was never notified by plaintiff or Marconi that it infringed upon the Marconi patent in suit (I R. 774). What is of even greater significance, when the Stone patent was cited against Marconi's application in the Patent Office, Marconi acquiesced in Stone's priority, and purportedly limited his claims expressly or by inference to the use of the "variable inductances" in the *antenna* circuits, stated in his specification to be "essential elements" in his invention (see p. 28, *supra*).

(iii) *Summary*

Thus, in sum, the court below properly held that Stone anticipated Marconi's transmitter claims 1, 3, 6, 8, 11, and 12, because Stone, like Tesla, disclosed a charging circuit in the transmitter for causing oscillations of a desired frequency, and an antenna circuit coupled to the charging circuit through a transformer, and Stone disclosed the tuning of the two transmitter circuits to the same frequency.[39]

The court was equally corrected in holding that Stone anticipated Marconi's receiver claims here involved (claims 2, 13, 14, 17, 18, and 19) for

[39] Indeed, as pointed out above (pp. 69–70), Stone further disclosed loose coupling of the two circuits in conjunction with the plain gap persistently oscillating circuit which had been known to the art as such since 1894 (p. 35, *supra*, and footnote 32, p. 75, *infra*).

Stone disclosed loosely inductively coupled antenna and detector circuits in the receiver, both tuned to the frequency being received.

Similarly, the court was correct in holding that Stone anticipated the combined transmitter and receiver claims (claims 10 and 20). Claim 10 is the only claim requiring that the four circuits shall actually be in resonance with each other; it does not require tuning by a variable inductance and hence in any aspect is readable directly upon the Stone disclosure. Indeed, this claim was apparently inadvertently allowed in the Patent Office, as we shall show (n. 34, p. 76, *infra*). Claim 20, which also covered the transmitter and receiver, was likewise properly held anticipated by Stone, since if the four circuits are in electrical resonance with each other, then there must be means for bringing them into resonance. Stone disclosed such syntony for all four circuits, and justifiably left it to those skilled in the art to utilize any of the well-known means to achieve such synchronization.

The court's findings of fact as to anticipation by Stone thus sustain the ultimate findings of invalidity of Marconi's patent, and are adequately supported by the evidence.

(c) Marconi's "variable inductance" in the antenna circuit cannot save his patent

The only difference between Stone's disclosure and the claims of Marconi's transmitter group

was the use by Marconi of a "variable inductance" in the open antenna circuit to tune that circuit, in lieu of tuning it otherwise, as by adjusting the length of the antenna wire. This was the feature upon which the Marconi patent was allowed. We submit that this involved no novelty since it had already been disclosed in the earlier Lodge patent, and in any event was not a patentable invention.

The original Marconi application, filed November 10, 1900, was repeatedly rejected by the Patent Office examiners because of the prior art.[30] For example, a letter of rejection on June 3, 1902, held that the claims specifying a variable inductance were not patentable in view of Tesla and Lodge, and that an adjustable or variable condenser was not patentable over Tesla.[31] The ap-

[30] For example, the Braun British patent No. 1862 of 1899 (Ex. Z-2, V R. 3620); Lodge patent No. 609,154 (p. 46, *supra*); Marconi patent No. 627,650 (p. 53, *supra*); and Tesla patent No. 645,576 (Ex. X-2, V R. 3662); cited by the Examiner V R. 3982, 3983, 4002. The Braun British patent and the corresponding Braun U. S. patent No. 797,344, granted August 15, 1905, upon original application filed February 6, 1899 (Ex. X-6, V R. 4006), disclosed a transmitter consisting of a separate charging circuit with spark gap and condensers, coupled to the antenna circuit by an oscillation transformer consisting of two inductance coils. These patents did not refer directly to tuning the circuits, but at that date the art was fully conversant with the fact that they should be, since Hertz, Lodge, Tesla, and Marconi (in No. 627,650) had fully appreciated and discussed its desirability.

[31] The examiner's letter of rejection, dated June 3, 1902, was as follows (Ex. X-5; V R. 4002):

"Claims 4, 13, 14, and 16, which specify a variable inductance and means for adjusting the inductance, are not pat-

plication was then abandoned and no action taken until October 6, 1903, when a petition to revive was filed, with an amendment containing all the claims here involved except claim 19 (V R. 4003). The examiner recommended that it be denied on account of the prior art,[*] and the Commissioner denied it on December 2, 1903 (V R. 4040). Some months later, another petition for revival was presented (*id.* 4043) and was granted by the Commissioner on March 28, 1904 (*id.* 4066). The case was immediately referred to a new examiner, who on March 31, 1904—only three days later—allowed all but four of the rejected claims (*id.* 4068).

The sole basis for the allowance was that although the earlier Stone patent No. 714,756, like the Marconi application, showed a system in

---

entable over Tesla because Lodge, of record, has shown that it is old to adjust the period of the circuit by a variable inductance; and claims 3 and 5, which specify an adjustable condenser, are not patentable over Tesla because applicant has shown in his prior patent 627,650, that this adjustment may be produced by a variable condenser. Since it is impossible to exactly calculate the values of the electro magnetic constants of two circuits for the purpose of making their time periods agree, it is fair to assume that the electrical oscillator of Tesla must necessarily be made with an adjustable inductance or condenser, or both."

[*] Particularly Tesla patents No. 645,576 and 649,621, Fessenden patents Nos. 706,735 and 706,736, Stone patents Nos. 714,756 and 714,831, and a paper presented by Pupin in December 1899 (V R. 4022). The examiner stated that Stone had disclosed "tuning a closed persistently oscillating circuit with the vertical transmitting wire as well as the advantages resulting therefrom," with the closed and open circuits "inductively connected" (V R. 4023).

which the circuits were in resonance with each other. Stone attained resonance (in the view of the new examiner) by adjusting the length of his aerial conductors, whereas Marconi attained the same result by including a variable inductance in the aerial circuit. The examiner accordingly allowed all claims which included that element (*id.* 4069). And the four remaining claims (claims 4, 5, 6, and 7) were held by the examiner to be allowable if amended by inserting a reference to a "variable inductance" in each claim (*id.* 4070).

The narrow ground upon which Marconi's application was allowed by the new examiner—that it included an inductance coil for tuning the aerial already shown by Stone[1]—was clear error. For, as the former examiner had held, Lodge had already disclosed such an inductance coil, and had taught its use in precisely the same manner for tuning the same kind of aerial used by Stone.

---

[1] Marconi's amended specification, and his patent as issued, represented the use of the variable inductance a and a' to be one of the "essential elements" required by his invention (Ex. X-5; V R. 3908; Ex. 21, IV R. 2791, lines 50-70).

[2] Because of the examiner's reliance upon the variable inductance coil in the antenna circuit, his allowance of claim 10, the only claim in Marconi's patent which does not require tuning by a variable inductance, was apparently inadvertent, and doubtless attributable to the misleading statement in Marconi's amendment (Ex. X-5; V R. 4073) that the "claims now presented, all include an elevated conductor, or a circuit which is a good radiator of electrical waves, and means for adjusting the time of such elevated conductor or radiating circuit."

This was the view of the court below in holding the Marconi patent anticipated, and its decision is fully sustained by the evidence.

Lodge in his patent No. 609,154 of August 16, 1898, had included a variable inductance in the antenna circuits at the transmitter and receiver for the purpose of tuning them (see pp. 46–53, *supra*). Marconi merely applied the function and mode of operation of Lodge's variable inductance without change to tune Stone's antenna circuit. Moreover, the use of Lodge's variable inductance in the antenna circuit, in lieu of tuning by adjusting the length of wire, had no practical effect upon the operation of the apparatus. The Stone system functioned in precisely the same way under either method, and no new result was accomplished. The combining of Lodge's feature with Stone's circuit was nothing more than the "skill of the calling," for to those skilled in the art, the variable inductance was plainly susceptible of, and indeed intended for, such use. Certainly, this exercise of ingenuity fell far below the level of invention.[8]

The court below therefore properly held that Stone in conjunction with Lodge anticipated the only feature of Marconi's transmitter which the

[8] *Cf. Electric Cable Joint Co.* v. *Brooklyn-Edison Co., Inc.*, 292 U. S. 69; *Paramount Corp.* v. *Tri Ergon Corp.*, 294 U. S. 464, 473; *Altoona Public Theaters, Inc.* v. *Tri Ergon Corp.*, 294 U. S. 477, 486; *Toledo Pressed Steel Co.* v. *Standard Parts, Inc.*, 307 U. S. 350, 356.

Patent Office regarded as novel, and which was not anticipated by Stone alone.

4. *Prior litigation upholding Marconi patent No. 763,772 is distinguishable*

Plaintiff cites a prior decision of a British court holding the corresponding British patent valid, and two decisions in the lower federal courts favorable to the Marconi patent in suit. These constitute little authority on the question of validity in the case at hand, since in two of the decisions the Stone defense was not raised; and in the third Marconi's patent was held not infringed.

(a) Corresponding British Patent

Marconi v. *British Radio Telegraph & Telephone Co.*, 27 T. L. R. 274, 28 R. P. C. 18 (Ex. 7; IV R. 2525), involved the Marconi British Patent No. 7777 of 1900 (Ex. 34; IV R. 2606). This patent, which claimed four-circuit tuning (IV R. 2614), was upheld as against the prior art by Mr. Justice Parker in the High Court of Justice (the case was not appealed). His decision, rendered on a record which contained no reference to the work of Stone, attributed all of Marconi's improvement to the radiation of prolonged oscillations from the transmitter by slowly feeding to the radiating or antenna circuit the energy of a closed, persistently oscillating charging circuit, by means of loose coupling between those circuits. But these features, as the court

below held, were previously disclosed in the United States by Stone; and since the work of Stone was not before Judge Parker in the English case, that decision is of no authority respecting the Stone defense. Indeed, far from aiding the plaintiff here, the English decision, as will be shown herein (pp. 81 *et seq.*), supports defendant's contention that its apparatus did not infringe Marconi's patent in suit.

(b) *Marconi Wireless Telegraph Co. of America v. National Electric Signaling Co.*, 213 Fed. 815

In the above captioned case, Judge Veeder in the Eastern District of New York held Marconi's United States patent here involved to be valid and infringed. The apparatus alleged to infringe consisted of a plain gap, persistently oscillating charging circuit, loosely coupled to the antenna circuit, as in the English case. Although the court recognized that "the broad claim of invention resides * * * in the independent adjustment of the capacity and self-induction of the four circuits, two at the transmitting station and two at the receiving station," the work of Stone was not referred to. Moreover, Judge Veeder virtually followed the reasoning in the British case (213 Fed. 848–849), and in his opinion the supposed novelty was found to inhere in features other than the tuning. For example, Judge Veeder stated:

> Marconi's improvement in his second patent, upon his own prior apparatus, and his solution of the difficulty involved in Lodge's compromise, consists in the substitution for a single circuit in both transmitter and receiver of a pair of circuits, one of which is so constructed as to radiate or absorb readily and the other to oscillate persistently and be a good conserver of energy * * * (p. 846).

For these two reasons, this case (which did not go to the circuit court of appeals) adds nothing persuasive to the British case, but like the British case, supports defendant's contention of noninfringement.

(c) *Marconi Wireless Telegraph Co. of America* v. *Kilbourne & Clark Mfg. Co.*, 239 Fed. 328, affirmed 265 Fed. 644

Judge Netterer in the Western District of Washington held the Marconi patent in question not infringed, mainly because it was construed in the light of the prior Stone invention to exclude quenched gap transmitters—the principal devices here charged to infringe. Although the district court entered a formal finding as to validity, that conclusion, in view of the decision as to noninfringement, is little more than *dictum* and would not be entered under more recent practice in like circumstances.* For while the Stone

---

* *Electrical Fittings Co.* v. *The Thomas & Betts Co.*, 307 U. S. 241.

defense was before the court, it was relied on solely to sustain the defense of "noninfringement of the invention as limited by the prior art," and the circuit court of appeals in affirming the decision as to noninfringement expressly recognized Kilbourne & Clark's position in this respect (265 Fed. 646). The court's references to validity must therefore be treated as having been made *obiter*. Of even greater significance in depriving that case of any weight on the issue of validity is the fact recognized by the court below (I R. 97–99), that Judge Netterer did not consider the earlier Lodge patent No. 609,154 read together with the earlier Tesla patent No. 645,576, which was the alternative basis for the conclusion of invalidity below. Indeed, as regards the feature here involved, the *Kilbourne & Clark* case favors defendant's contentions, since Judge Netterer there specifically stated that tuned circuits and even four-circuit tuning were known prior to Marconi (265 Fed. 655, 661).

In the *Kilbourne & Clark* case, the apparatus alleged to infringe employed a quenched gap and tight coupling, and had no persistently oscillating charging circuit.[*] The district court described it as one which transfers the energy by a single

[*] These features were found to characterize defendant's transmitters in the present case, which are the principal apparatus alleged to infringe (Findings LXVIII, LXIX; I R. 4344).

impulse, as distinguished from other means (239 Fed. at 345):

> Such conversion is known to the art as impulse excitation. Impulse excitation of the oscillating currents is one in which the energy is set in motion within the oscillating, radiating circuit by a single impulse, as distinguished from a transfer of energy by other means.

This feature was held to distinguish the quenched gap transmitter of Kilbourne & Clark from Marconi's patented transmitter. After pointing out that the antenna circuit of Kilbourne & Clark's "impulse transmitter" was tuned to the desired frequency, and that the charging circuit (called "a disturbing circuit") had fixed elements of capacity and inductance, the court stated (p. 348):

> The difference in the operation of the defendant's impulse transmitter and the plaintiff's type of transmitter is in the fact that there is an entire absence of resonant tuning in the impulse transmitter, whereas in the tuned, coupling circuit transmitter, for any change in wave length there must be a change of tune of the two associated circuits, so as to keep them in resonance. The defendant's impulse transmitter is electrically the same as Lodge's and carries out his thought with relation to the transmission of energy.

The court's conclusion as to non-infringement because of differences in mode of operation was thus rested on the facts that Kilbourne & Clark used a high resistance spark gap which would rapidly cut off the charging circuit, damping further oscillations in that circuit but leaving the antenna circuit free to oscillate at its own natural frequency, and that the two circuits in the transmitter were neither loosely coupled nor required to be attuned to exact resonance with each other; whereas the essence of the Marconi system was the low resistance plain gap with its persistently oscillating circuit (i. e., reservoir circuit) loosely coupled to the antenna circuit and tied electrically to the antenna circuit for the entire period of persistent oscillation during which the energy is gradually transferred. This clear distinction in apparatus, producing a different mode of operation, lead inevitably to the court's conclusion of non-infringement. Because of this conclusion, the court held it unnecessary to enter into any detailed discussion of the validity of Marconi's patent.

It did, however, hold Kilbourne & Clark's apparatus to be identical with Lodge's transmitter [35] and, as to the feature of synchronization,

[35] Judge Netterer stated: "The operation of Lodge patent, Fig. 2, is identical with defendant's in using impulse charging and variable inductance coil in the antenna. No reservoir circuit is used, and, when the radiating circuit is charged, it is entirely separated from the source of supply circuit which necessarily has some natural period" (239 Fed. 350).

it held that Marconi was not the first to invent tuned circuits nor even four circuits tuned to the same frequency (239 Fed. 328, 338–342).

Although the decree of non-infringement entered by the district court recited the validity of the Marconi patent, the Circuit Court of Appeals for the Ninth Circuit, affirming the decision below, noted that defendant's counsel "did not find it necessary to depend upon the validity of the Marconi patent for a defense" (265 Fed. 644, 646). This observation, coupled with the absence of any statements or reasoning in the district court's opinion as to validity, renders the recital of validity purely formal and in effect entered upon consent. Such a decree would scarcely be entered today, and is entitled to little weight. *Electrical Fittings Corp.* v. *The Thomas & Betts Co.*, 307 U. S. 241.

Hence, nothing in the *Kilbourne & Clark* case can serve as authority against the propriety of the decision below, in accepting the Stone (and Lodge) defense as a prior disclosure in anticipation of the Marconi patent. Indeed, upon the question of infringement the *Kilbourne & Clark* case is in accord with defendant's contention that its quenched gap, tightly coupled, transmitter apparatus did not infringe Marconi's patent, as will hereinafter appear.

Point II

MARCONI PATENT NO. 763,772, EVEN IF VALID, WAS NOT INFRINGED BY DEFENDANT'S APPARATUS

In the court below, the defendant urged at the close of the hearing that Marconi patent No. 763,772 had been proved not only invalid for anticipation, but also not infringed by defendant's apparatus.[20] The court below made evidentiary findings of fact which, we believe, would adequately support a conclusion of non-infringement, but held in its opinion that it was unnecessary to pass upon that defense because of the conclusion as to invalidity of the patent (1 R. 94, 101). Since we consider that the defense of non-infringement is a sufficient ground to sustain the judgment in the Government's favor even if that court erred in its holding of invalidity, we reassert that defense before this Court. *Stelos Co.* v. *Hosiery Motor-Mend Corp.*, 295 U. S. 237.[21]

---

[20] Record, C. Cls. No. 33,642; pp. 3883, 4133 *et seq.*

[21] Nothing in *Esnault-Pelterie* v. *United States*, 299 U. S. 201, precludes such a finding by this Court. It was there held that a judgment of the Court of Claims in a patent case could not be sustained in the absence of ultimate findings concerning either validity or infringement, and the case was remanded for such findings. Besides being distinguishable from the instant case—in which an ultimate finding of invalidity was made—the *Esnault-Pelterie* decision was rendered on certiorari to the Court of Claims under Section 3 (b) of the Act of February 13, 1925, which, before the amendment of May 22, 1939, permitted only "the findings of fact, the conclusions of law, and the judgment or decree" of the Court of Claims to be brought up. The amendment of

1. *Criteria available to test infringement*

In surveying the prior art to determine possible elements of novelty in Marconi's disclosure, the court below stated that Marconi in this case was attempting to claim the tuning of all four circuits as his improvement and as the feature infringed (I R. 31–38; p. 5, *supra*). The court then found that four-circuit tuning had been known and disclosed in the prior art by Stone, as well as by Tesla's patent taken with that of Lodge (Findings LVIII and LXII; I R. 57, 58). Hence, under the approach adopted below, there remained no feature of Marconi's asserted invention which could be used as a criterion to test the allegations of infringement. To obtain such a criterion we may look to the only decisions which have recognized and upheld any element of novelty in Marconi's patent—the decision of Judge Veeder in *Marconi Wireless Telegraph Co. of America* v. *National Electric Signaling Co.*, 213 Fed. 815 (E. D. N. Y.), and the decision of Judge Netterer in *Same* v. *Kilbourne & Clark Mfg. Co.*, 239 Fed. 328 (W. D. Wash.).

May 22, 1939 (c. 140, 53 Stat. 752), now permits the entire record in the Court of Claims to be reviewed in the Supreme Court on certiorari, as is true on certiorari to a circuit court of appeals under Section 240(a) of the Judicial Code. The scope of review in patent matters coming from a circuit court—as did *Stelos Co.* v. *Hosiery Motor-Mend Corp.*, 295 U. S. 237—would therefore appear to apply to review of patent decisions of the Court of Claims under the 1939 amendment, when the evidence is brought up, as here.

affirmed 265 Fed. 644 (C. C. A. 9). We may also look to the decision of Justice Parker in respect to the corresponding British patent, *Marconi* v. *British Radio Telegraph & Telephone Co.*, 27 T. L. R. 274, 28 R. P. C. 18 (IV R. 2525). Even if these decisions be accepted as properly establishing invention in Marconi's patent over the prior art, the conclusion is inescapable that defendant's devices do not infringe.

Marconi's transmitter, to the extent held novel by these prior adjudications, involved the use of a persistently oscillating charging circuit, loosely coupled to the antenna circuit, and feeding only a small part of its energy thereto on each oscillation, so that the radiation in the antenna circuit for each discharge in the charging circuit would be prolonged, i. e., spread over a longer train of oscillations. Thus, Justice Parker in considering the Marconi British patent, found that from his transmitter Marconi desired to radiate a long train of waves of single frequency, as Lodge had wished to do; that instead of attempting suddenly to charge the antenna circuit by impulsive rush and then leave it to oscillate freely, as Lodge had done, Marconi proposed to feed it the energy to be radiated, a little at a time; that for this purpose Marconi proposed to use a charging circuit which was a persistent oscillator (i. e., a circuit of low resistance, shown as having a low-resistance plain spark gap, so that its oscil-

lations would not soon damp out) and to loosely couple this charging circuit to the antenna circuit so that only a small part of the energy of the charging circuit would be delivered to the antenna circuit on each oscillation, thus spreading the energy being radiated over a longer number of oscillations (i. e., lengthening the wave train) and at the same time avoiding the generation of a double frequency in the antenna circuit. The decision indicated that the entire improvement of Marconi's system flowed from the prolonging of the transmitted wave, which, when picked up by the antenna circuit of the receiver, thereby induced and then built up the amplitude of the oscillations in the coherer circuit (itself already a persistently oscillating circuit) and thus effectively actuated the receiver. Justice Parker attributed no novelty to the receiver,[1] and only incidentally adverted to the necessity of tuning the respective circuits to resonance, a requirement well understood by the prior art.

Judge Veeder in the *National Electric* case and Judge Netterer in the *Kilbourne & Clark* case made substantially the same analysis of the Marconi patent in suit. Tested by the features regarded as novel in these cases, the conclusion inevitably follows that defendant's apparatus did not infringe the Marconi patent in suit.

---

[1] No claim of the British patent covered the receiver apart from the transmitter (IV R. 2613, 2614).

2. *Defendant's transmitters*

The transmitters here charged to infringe were of three types. By far the greater number were quenched gap transmitters (Finding XLVI; I R. 40). A few used the rotary gap (Finding XLIX; I R. 41), and only a very few early transmitters were of the plain gap type (Finding XLVI; I R. 41).

(a) Quenched Gap Transmitters

The quenched gap transmitters, comprising practically all of the defendant's transmitter types,* employed in their charging circuit a high-resistance "quenched gap" (instead of a low resistance plain gap) and relied on relatively tight coupling quickly to transfer the energy of the charging circuit to the antenna circuit in the relatively few oscillations permitted by the high resistance gap.† Because the charging circuit in-

---

* The Telefunken type (Ex. 79); Kilbourne & Clark type (Ex. 95); the type manufactured by the Navy (Ex. 93); Wireless Improvement type (Ex. 88); Simon type (Ex. 89); Lowenstein transmitter (Ex. 101); National Electric Supply type (Ex. 90); and Wireless Specialty type (Ex. 87).

† The "quenched gap" consists of a series of gaps or open spaces separated by cooling plates. The gaps are of high resistance, and the plates separating them offer large cooling surfaces, thereby tending to cool and extinguish the arc of current quickly. In the plain gap, on the contrary, there is only one gap or open space, and the terminals offer a minimum of cooling surface; hence the gap has low resistance, facilitating persistence of the spark. The conventional symbol for the quenched gap is a series of parallel lines of equal length, as G in Ex. 89.

cluded a high resistance gap tending to damp-out the oscillation quickly, and because the tight coupling enabled the charging circuit to part with its energy rapidly, it was not a persistent oscillator. The high resistance gap "quenched" the spark quickly, after but a few oscillations; the charging circuit then ceased to oscillate, after transferring the energy rapidly to the antenna circuit; and the antenna circuit then continued to oscillate at its own natural frequency. (Finding XLVIII; I R. 43.)

Further to aid in quickly suppressing the oscillation of the charging circuit, the frequency of that circuit was in practice preferably adjusted so that it would *not* be in tune with the antenna circuit." With such detuning, after a few cycles

---

"This detuning is explained by defendant's expert Loftin (II R. 991, 1031) and illustrated by him in Exhibit D-3. The *Electrician* article of November 10, 1911 (Ex. C-5, V R. 39 g 3993) pointed out:

"To give the best result it is necessary that the reaction of the secondary circuit should assist the quenching in the primary, and for that reason the two circuits are slightly mistuned, namely, to the extent of about 2 percent. The closer the coupling the greater must be the mistuning."

Close coupling itself effects detuning and produces the "double hump" phenomena tending to prevent persistent oscillation of the charging circuit (see p. 26, n. 8, *supra*). Consequently, the instructions given by the Army Signal Corps to its personnel "that tuning of the closed and open circuits to resonance and the determination of the correct coupling between them are the two most important adjustments in a quenched gap transmitter," which plaintiff cites to distinguish defendant's quenched gap transmitters from those held not to infringe in the *Kilbourne & Clark* case (Pl. Brief,

of oscillation, the voltages of the two transformer coils (one in the charging and one in the antenna circuit) are in opposition with each other and hence stop the current flow in the charging circuit. Because the two circuits are thus coupled for only a brief instant, and because the quenched gap prevents persistence of oscillation in the charging circuit, the energy must be transferred rapidly from the charging circuit to the antenna circuit, which requires that the circuits be coupled tightly. It is true that during the extremely short time in which the current oscillation in the charging circuit continues, there is the generation of a double wave and diminution of efficiency which results from tight coupling and nonresonance, but these phenomena are only transitory. The close coupling is permissible and useful notwithstanding this minor fault because, when the charging circuit is cut off, its interference ceases, the antenna has received a much higher charge of energy than it would with the slow-feeding system of Marconi, the antenna is then free to oscillate at its own natural period, and it radiates a single frequency of greater initial amplitude (Ex. D–3, V R. 3628, II R. 991–998, 1031).

As was held in the *Kilbourne & Clark* case, *supra*, this principle was originally disclosed by

p. 43) are immaterial, for the "correct coupling" of defendant's apparatus, being tight, necessarily results in a detuning. Moreover, the apparatus does not employ the "persistent oscillator."

Lodge in 1898. In his patent No. 609,154, he employed a plurality of spark gaps, and his specification (p. 2, lines 57–85) described the manner of charging the aerial by "aerial disruption or impulsive rush," whereby the "charges so communicated are left to oscillate free from any disturbance due to maintained connection with the source of electricity" (see Fig. 4 of Lodge patent, p. 47, and n. 19, p. 48, *supra*). In 1906, Professor Wien in Germany redesigned Lodge's invention, devised a suitable spark gap apparatus having even more gaps than Lodge's system (since known as "quenched gap" apparatus) and arranged that the charging circuit and the antenna circuit should be out of tune during the charging process in order to aid quick extinguishment of the current flow in the gaps, thus cutting off the charging circuit from the antenna circuit as soon as possible."

---

[*] Professor J. A. Fleming, an expert associated with the Marconi Company (I R 554), in an article in *The Electrician* on June 11, 1909, explained and diagrammed the difference between the plain gap and the Telefunken quenched gap systems as follows (Ex. B 5; V R 3897):

"The Telefunken discharger is based on the known fact that the damping of very short sparks is extremely large, and that if we can 'quench' or stop the primary oscillations after one or two swings the secondary circuit then continues to oscillate freely within a single period, as shown in Fig. 1. * * *

"Finally, as the whole of the energy transferred to the secondary circuit expends itself in the production of radia-

The substantial difference between Marconi's and the defendant's transmitters in arrangement, mode of operation, and result are thus apparent. Marconi's structure involves a *low-resistance plain spark gap* in the charging circuit, *loose-coupling* between antenna and charging circuits, and *exact tuning* of these circuits. This *decreases* the resistance of the charging circuit and renders it a *persistent oscillator*, a reservoir-like conserver of energy. Because the coupling is loose, it feeds to the antenna circuit, on each oscillation, only a little of its energy, thereby prolonging the trans-

tion of one single wave length it must be more economical than methods which generate waves of two wave-lengths, but capture at the receiver radiation conveyed by only one of these wave-lengths."

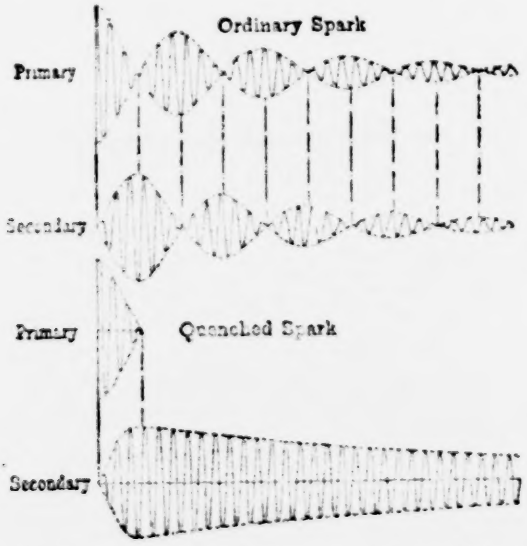


FIG. 1.—OSCILLATIONS IN INDUCTIVELY-COUPLED CIRCUITS.

mitted wave, but reducing its initial power. Marconi's charging circuit is thus electrically tied to the antenna circuit, as a driver, throughout its prolonged period of persistent oscillation, and does not leave the antenna circuit free to oscillate entirely by itself. The useful signal is transmitted *while* the persistent oscillation continues. (Ex. R–2, Loftin sketch J; V R. 3594, II R. 923–929.) *

The defendant's structures, on the contrary, involve a *high resistance quenched gap* in the charging circuit, *tight coupling* between the two transmitter circuits, and *detuning* of those circuits, thereby *increasing* the resistance of the charging circuit, preventing it from being a persistent oscillator, and providing for delivery of its energy to the antenna circuit "in a rush," after which it ceases to oscillate, leaving the antenna circuit free to oscillate at its own natural frequency. The useful signal is radiated *after* the charging circuit has delivered its energy to the antenna circuit and has ceased to oscillate. (Ex. D–3, Loftin sketch O; V R. 3628, II R. 991–998.)

The differences between Marconi's and the defendant's devices are tabulated, for convenient reference, in Table I, following:

---

* *Marconi* v. *British Radio Co.*, 27 T. L. R. 274, characterized Marconi's charging circuit as a reservoir feeding energy to the antenna in a manner similar to clock escapement mechanism.

TABLE 1

STRUCTURE

Marconi's transmitter	Defendant's quenched gap transmitter
(1) *Low resistance*, plain spark gap in the charging circuit.	(1) *High resistance*, quenched gap in the charging circuit.
(2) *Loose* coupling between the charging and antenna circuits.	(2) *Tight* coupling between the charging and antenna circuits.
(3) *Exact tuning* of the two transmitter circuits.	(3) *Detuning* of the two transmitter circuits.

OPERATION

(1) The low resistant gap *decreases the* resistance of the charging circuit, making it a persistent oscillator.	(1) The high resistant gap *increases* the resistance of the charging circuit, preventing it from being a persistent oscillator.
(2) The loose coupling feeds to the antenna circuit on each oscillation only a little of the energy, prolonging the transmitted wave but reducing its initial power.	(2) The tight coupling delivers to the antenna circuit on each oscillation a large part of the energy in a rush.
(3) No useful signal is transmitted from the antenna circuit while the persistent oscillation continues in the charging circuit.	(3) The useful signal is transmitted from the antenna circuit after the charging circuit has ceased to operate.

RESULT

The transmitter transmits a prolonged series of oscillations not initially of very great strength but continually replenished by energy being withdrawn from the charging circuit so long as it persists in oscillation.	The transmitter transmits a series of oscillations of such greater initial strength and which die out at the natural rate of damping of the antenna circuit.

Contrary to Marconi's theory, the "impulsive rush" operation of defendant's transmitter results in a great increase in the efficiency of the quenched gap over the plain gap apparatus of the Marconi patent (11 R. 1139), for there is no resonant retransfer of energy from the antenna circuit to the charging circuit after the antenna has been charged and commences to radiate at its natural frequency; and the transmitter's useful radiation has an initial amplitude or power much

greater than that obtained by slow feeding (*cf.* Ex. O-2, P-2, R-2, D-3; III R. 2120, 2291–2292).

Defendant's quenched gap apparatus is like that involved in *Marconi Wireless Telegraph Co. of America* v. *Kilbourne & Clark Mfg. Co.* (*supra*, pp. 80–84). This the Circuit Court of Appeals for the Ninth Circuit held did not infringe Marconi's patent because the quenched gap transmitters did not use the persistently oscillating charging circuit slowly feeding the energy to the antenna circuit, but instead followed Lodge's principle of charging the antenna quickly and then leaving it free to oscillate at its own natural frequency.

In summary: (1) The Lodge patent pointed the art along one path when it suggested that the antenna circuit be charged by "impulsive rush" to obtain in it an *initially strong oscillation*, and when it used a high resistance series of three or four spark gaps in the charging circuit to cause it quickly to stop oscillating and driving the antenna circuit, so that it would leave the antenna circuit free to oscillate at its own natural frequency and rate of damping. (2) Marconi pointed the art away from this principle, and in his system charged the antenna circuit only a little at a time, to obtain a *weaker but more prolonged series of oscillations* in the antenna circuit, using a single low resistance plain gap in the charging circuit to cause it to continue or

persist in oscillating and driving the antenna circuit during practically the entire period of radiation. (3) The Wien quenched gap systems employed by defendant returned to the path pointed out by Lodge, and travelled that path to a point still further removed from Marconi's principle than that at which Lodge had stopped, for Wien increased the number of gaps (to nine in the arrangement photographed at V R. 3906A for example), thus increasing their cumulative resistance, and also provided them with cooling flanges, all to extinguish the spark even more quickly. This produced still quicker cut-off of the charging circuit and still quicker stopping of any driving of the antenna circuit so as to leave the latter free to oscillate alone.

This difference in basic principle required differences in arrangements of apparatus. Marconi, in order to practice his slow feeding of energy during a large number of oscillations, required loose coupling and very exact tuning of the charging and antenna circuits to obtain a sufficient oscillation of the desired frequency in his antenna circuit. The quenched gap system, on the other hand, because it fed its energy in a rush and then allowed the antenna circuit to oscillate by itself, needed no such loose coupling or exact resonance, but preferred the opposite. In its preferred form, the two circuits were not only tightly coupled but intentionally de-tuned to further aid in

quickly stopping any prolonged driving of the antenna circuit by the charging circuit.

Since the prior art Lodge patent is the basis of the quenched gap system, Marconi's patent cannot embrace the latter without including and being invalidated by the Lodge disclosure.

That the quenched gap transmitter differs markedly from the plain gap type is further evidenced by the commercial displacement of the latter by the former, notwithstanding that the quenched gap transmitter went back to a principle antedating Marconi's patent. Soon after its introduction in this country in 1909, the quenched gap system displaced the plain gap "persistently oscillating" charging circuit of the patent in suit because its different mode of operation resulted in such greatly increased efficiency (II R. 1178). The Navy adopted the quenched gap and abandoned the plain gap apparatus in or about 1911 (II R. 1044). After 1911 the plaintiff's own United Wireless Company manufactured *quenched* gap transmitters exclusively, and because of the inability of the loose-coupled persistent oscillator to transmit beyond a short range (II R. 1044; III R. 2201) it abandoned the tuned circuit type (II R. 1181, 1210–1213) except at some existing stations (II R. 1269, 1270) and except for emergency use in war time.

Thus, upon the interpretation of the Marconi patent adopted by the courts in the few cases

which have considered and upheld it, upon principle, and in light of the prior art, defendant's quenched gap transmitters do not infringe. The differences in mode of operation and result requiring this conclusion are set forth in the evidentiary findings made below, which are supported by substantial evidence; and these evidentiary findings afford a sufficient foundation to uphold the judgment for defendant as to quenched gap transmitter systems on the ground of non-infringement.

(b) Rotary Gap Transmitters

A few of the transmitters alleged to infringe were of the rotary gap type, which consists of two widely spaced stationary electrodes and a rotating disc between them, having a number of spaced studs. The spark jumps from the stationary electrodes to the studs of the rotating disc when they are brought into alignment, and further rotation of the disc moves the studs away from the electrodes, lengthening the gap quickly and extinguishing the spark. As the court below held (Finding LXIX, I R. 44), this gap is similar to the quenched gap in that it effects a quenching of the spark as the moving electrodes recede from the stationary electrodes. Thus the rotary gap is simply another means for quickly quenching the spark and preventing the charging circuit from being a persistent oscillator. The finding of the quenching action of the rotary gap is not chal-

lenged by plaintiff; consequently the rotary gap transmitters must stand or fall with those containing the quenched gap, for they also employed the principles set forth by Lodge and avoided Marconi's system, as was urged below. The reasons urged above, to support the conclusion that quenched gap transmitters did not infringe, are equally applicable here.

(c) Plain Gap—Direct Coupled Transmitters

The few plain gap transmitters employed by defendant had the antenna circuit directly coupled across an inductance in the charging circuit, without any separate swamping inductances to loosen the coupling, as shown in the drawing in Finding XLVI, I R. 41. These transmitters thus did not embody the "essential" features of the Marconi patent, in which both loose coupling and persistent oscillation were required to attain Marconi's mode of operation and result. While in these plain gap transmitters the charging circuit had fewer gaps than that of Lodge, and hence would not cut off as quickly and efficiently, Lodge's mode of coupling the antenna and charging circuits to a common inductance (see illustration on p. 50, *supra*) was nevertheless common to these transmitters, and there is no evidence that they attained Marconi's slow feeding operation and result. For these reasons, as urged below, no infringement has been established in respect of the plain gap transmitters.

3. *Receivers*

We have shown above that the receivers charged to infringe the Marconi patent are so thoroughly grounded in the art prior to Marconi that if they infringe Marconi's receiver claims, those claims must necessarily be invalid for anticipation. The court below held these claims invalid, as it found no element in them not disclosed in the prior art. But if we turn to the other prior litigation on the patent, and on its British counterpart, we find that there is little basis even in them for any test of infringement of the receivers apart from the specific transmitters of Marconi.

In the prior litigation, no charge of infringement under the Marconi patent was brought or maintained against receivers except as parts of a system alleged to embody four-circuit tuning *and* the wave-prolonging loose coupled persistent oscillator at the transmitter. In the British case, Mr. Justice Parker indicated that the entire alleged improvement of Marconi's patent flowed from the supposed improvement of the transmitted wave (p. 78, *supra*), and Judges Veeder and Netterer followed substantially the same reasoning (pp. 79–84, *supra*). But, as we have already shown, these features are no part of the defendant's systems and, in any event, have no relevancy to the Marconi claims for receivers, *per se*. Hence even under the interpretation given Mar-

coni's patent by the courts which considered and upheld it, defendant's receivers are excluded from the valid scope of the patent. In any event, if any claim of the Marconi patent reads upon defendant's receivers, the identity of the prior art with such receivers is alone sufficient in our opinion to preclude any conclusion of infringement.[47]

PART TWO: FLEMING PATENT NO. 803,684

The court below found that Fleming patent No. 803,684, covering a use of a two-electrode vacuum tube, was not infringed, as charged, by defendants use of the three-electrode vacuum tubes in its receivers and transmitters, because the apparatus alleged to infringe was substantially different in structure, mode of operation and result from the device disclosed by Fleming. This decision is grounded upon adequate evidentiary findings of fact and upon substantial evidence. Moreover, apart from the question of infringement, the record and the findings of fact below would fully support the conclusion that the Fleming patent was invalid.

---

[47] As pointed out (pp. 54-55, *supra*), Marconi's own prior patent No. 627,650 disclosed inductive coupling of two tuned circuits at the receiver, with the detector circuit tuned by a variable condenser, and the antenna circuit tuned in ways also known to the prior art and clearly tunable by a variable inductance as taught by Lodge. We have also shown (*supra*, pp. 42, 50, 56 *et seq.*) that Tesla, Stone, and others had taught that the two receiver circuits should be tuned and preferably loosely coupled.

The Fleming patent employed a two-element vacuum tube, and claimed its use as a rectifier to render capable of indication the high frequency alternating currents of wireless oscillations. The court below found as facts that the earliest date available to Fleming for his alleged invention was November 16, 1904; that prior to this date, the two-element device described by Fleming had been disclosed by Edison and was known to be a rectifier or detector of low-frequency alternating currents;* that use of a similar two-element vacuum tube rectifier as a detector of high-frequency waves was also known prior to Fleming's date; that the Fleming patent, if valid, was restricted to this particular use of the known Edison device to rectify the received alternating currents of radio signals in order to operate a direct current indicator in the received energy circuit, and that on principle, and in view of the prior art, Fleming's particular manner of using Edison's two-electrode rectifier was not embraced in the defendant's differently arranged and differently operating three-electrode vacuum tubes (Findings LXV, LXVI, LXX, LXXI, LXXII, LXXIII, LXXV–LXXX; I R. 62–74). The court below then found as an ultimate fact (I R. 117) that Fleming's claims in suit—claims 1 and 37—were not

* The court committed inconsequential error in impliedly limiting the prior art to use of the two-element rectifier with low frequencies. The prior art was not so limited, as we shall show (*infra*, p. 121 *et seq.*).

infringed by defendant's devices and entered judgment accordingly (I R. 75, 182).

The court below made no ultimate finding on the issue of validity, because as is not unusual it decided to rest its decision on the ground of non-infringement. However, for either ground, the prior art is an essential frame of reference. On the issue of infringement, it is used to determine distinguishing features of the plaintiff's patent in order to establish the criteria by which to gauge the alleged infringing use; on the issue of invalidity, the prior art is itself the test of whether the alleged invention was a patentable invention. In either case, therefore, evidentiary findings regarding the prior art and a comparison between it and plaintiff's alleged improvement are necessary; and such findings were made by the court below, together with findings as to the structure and operation of the devices. From these findings, the court below concluded there was no infringement, and we submit that this conclusion was clearly correct. But we further urge that, even were that holding improper, the same evidentiary findings would require an ultimate finding of invalidity, in that the device disclosed by Fleming, and its uses, were fully known to the art before Fleming's earliest date. Moreover, we shall show that apart from want of invention, Fleming's patent was void because of unreasonable delay in disclaiming, as the court below held

in its opinion, and for the additional reason that the subject matter of the disclaimer was improper. All these grounds were urged below by defendant, and although the judgment for defendant in respect of the Fleming patent was placed primarily upon absence of infringement, we reassert them as alternative and additional grounds for sustaining the judgment below.[*] *Stelos Co.* v. *Hosiery Motor-Mend Corp.*, 295 U. S. 237.

Point III

The Fleming patent is invalid

1. *Disclosure of the Fleming Patent; Claims 1 and 37*

Patent No. 803,684, entitled "Instrument for Converting Alternating Electric Currents into Continuous Currents", was applied for on April 15, 1905 and granted on November 7, 1905 to plaintiff as assignee of Professor J. A. Fleming (Finding IV; I R. 8). Its specifications stated:

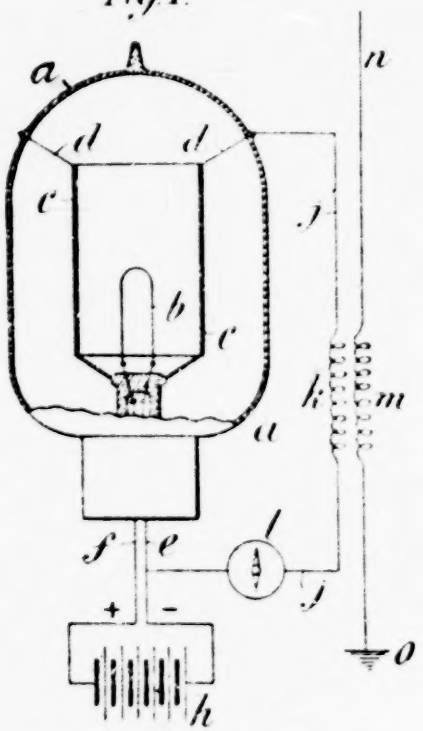
> This invention relates to certain new and useful devices for converting alternating electric currents, and especially high frequency alternating electric cur-

[*] Review of the art prior to Fleming is a necessary preliminary to a discussion of either infringement or validity. The latter issue, however, requires only a comparison between the prior art and Fleming's disclosures, while the issue of noninfringement calls for treatment of the alleged infringing structures as well. For convenience, we shall present our argument on invalidity after a review of the prior art, and follow with the discussion of noninfringement.

rents or electric oscillations, into continuous electric currents for the purpose of making them detectable by and measurable with ordinary direct-current instruments, such as a "mirror-galvanometer" of the usual type or any ordinary direct-current ammeter (Ex. 22; IV R. 2600, lines 11 *et seq.*).

Figure 1 of the patent illustrated the following apparatus to carry out the alleged invention (IV R. 2599):

Fig. 1.



Alternating current impulses are received through an antenna circuit *n o*. A transformer

m k couples the antenna circuit to a secondary circuit *c d j k j l c b*. In the latter circuit the element *b* is a carbon filament like that of an incandescent lamp (IV R. 2600, lines 85–86) and *c* is "a cylinder of aluminum open at the top and bottom, which surrounds but does not touch the filament" (*id.*, lines 87–90). The cylinder and the filament are enclosed in an evacuated vessel such as an ordinary lamp bulb *a*. The secondary coil *k* of the coupling transformer conducts the received alternating current to the cylinder *c* and the filament *b*. The indicating instrument or galvanometer *l* responds to the flow of current in this circuit.

The specification explained the operation of this device (IV R. 2601):

> The arrangement described above operates as an electric valve and permits negative electricity to flow from the hot carbon *b* to the metal cylinder *c*, but not in the reverse direction, so that the alternations induced in the coil *k* by the Hertzian waves received by the aerial wire *n* are rectified or transformed into a more or less continuous current capable of actuating the galvanometer *l* by which the signals can be read * * * (lines 18–27).
>
> * * * the aerial wire *n* may be replaced by any circuit in which there is an alternating electromotive force, whether of low frequency or of high frequency * * * (lines 30–34).

> Hence the device may be used for rectifying either high-frequency or low-frequency alternating currents of electrical oscillations * * * (lines 97–101).[20]

Only claims 1 and 37 of the patent are in suit, and read as follows (italicized letters refer to Figure 1):

> 1. The combination of a vacuous vessel (*a*), two conductors adjacent to but not touching each other in the vessel, (*b* and *c*), means for heating one of the conductors (*e*, *g*, battery *h*), and a circuit (*j*) outside the vessel connecting the two conductors. (IV R. 2601, line 125.)
>
> 37. At a receiving-station in a system of wireless telegraphy employing electrical oscillations of high frequency a detector comprising a vacuous vessel (*a*), two conductors adjacent to but not touching each other in the vessel (*b* and *c*), means for heating one of the conductors (*e*, *g*, battery *h*), a circuit (*j*) outside of the vessel connecting the two conductors, means for detecting a continuous current in the circuit (indicator *l*), and means for impressing upon the circuit the received oscillations (*e*, *g*, transformer coil *k*). (IV R. 2604, line 125).

---

[20] In Figure 2 of his patent, Fleming showed two of the vacuum tube rectifiers in reversed position so that current will flow through either one or the other of the valves during each half cycle of the alternation of current to provide two usable pul-sating direct currents. This arrangement is not involved in the present suit, nor is the arrangement of three tubes in parallel, shown in Figure 3 of Fleming.

Both claims were thus identical in their structural elements: a vacuum tube containing two adjacent but noncontiguous elements or electrodes, connected by a circuit outside the tube, one element being heated. The claims differed only in that claim 37 included "means for detecting" the continuous or direct current in the circuit between the two elements (the indicator *l*) and "means for impressing upon the circuit the received oscillations" (transfo mer coil *k*). In the patent as originally issued, another difference had existed: claim 37 had specified that the tube was to be used "in a system of wireless telegraphy employing oscillations of high frequency" whereas claim 1 was applicable to any use of the claimed device, including use with low frequency. This distinction was, however, eliminated by disclaimer filed November 17, 1915, restricting the combination of the elements of claim 1 to use "in connection with high frequency alternating electric currents or electric oscillations of the order employed in Hertzian wave transmission" (Ex. 22; IV R. 2505).[5] The result of the disclaimer was to limit both claims to use of the device for rectifying high frequency alternating waves or currents.

2. *The Art Prior to Fleming*

November 16, 1904, is conceded by plaintiff to be Fleming's earliest invention date for the patent

[5] The specification was correspondingly amended by disclaiming all references to low frequency alternating currents (IV R. 2605).

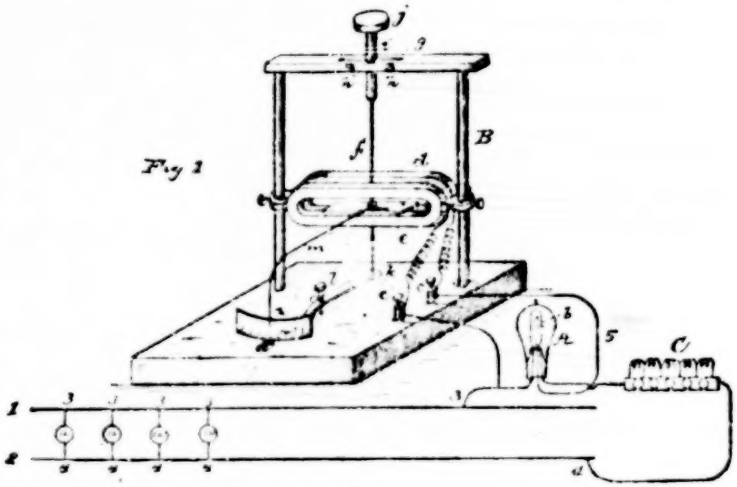
in suit (Finding LXVI, I R. 63). The art prior to that date begins with an invention of Thomas Alva Edison.

(a) The Edison Tube

Prior to 1884, the incandescent electric lamp as developed by Edison consisted of a vacuous glass tube or globe, containing a thin wire loop or filament, one end of which connected outside the globe to a resistance coil and thence to a generator, the other end being grounded outside the globe. The course of current through the filament in the partial vacuum caused it to become heated to incandescence. On October 21, 1884, Edison was granted United States patent No. 307,031, which announced:

> "I have discovered that if a conducting substance is interposed anywhere in the vacuous space within the globe of an incandescent electric lamp, and said conducting substance is connected outside of the lamp with one terminal, preferably the positive one, of the incandescent conductor, a portion of the current will, when the lamp is in operation, pass through the shunt-circuit thus formed, which shunt includes a portion of the vacuous space within the lamp. This current I have found to be proportional to the degree of incandescence of the conducter or candle power of the lamp. (Ex. J, IV R. 3297, lines 16–20).

Figure 1 of his patent showed this structure:



In this diagram, the filament circuit is wire *1*, *3* through filament *b*, resistance coils *C*, and wire *4* to the generator *2*. The "conducting substance" which is interposed "in the vacuous space within the globe" is the plate or electrode (unlettered) within the filament loop but not touching it, consisting of "a piece of platinum" (IV R. 3297, line 91). The "shunt-circuit" is from the plate electrode thence by wire *5* to contact *c* and coils *d* and *e* of a galvanometer *B*, then from the coil *e* of the galvanometer to contact *c'* and wire back to the filament circuit at *3*.

The description in the patent disclosed that (i) the vacuous space within the globe is a conductor of current between the plate electrode and the filamentary electrode, (ii) the strength of the current in the filament to plate circuit through the

vacuum within the globe depends upon the *temperature* of the filament, and (iii) the plate electrode is preferably connected to the *positive* side of the current supply. The claims of the patent are directed to the combination of the filament, plate and interconnecting circuit, including the galvanometer or indicating instrument. Claim 5, for example, is as follows:

> The combination, with an incandescent electric lamp, of a circuit having one terminal in the vacuous space within the globe of said lamp, and the other connected with one side of the lamp-circuit, and electrically controlled or operated apparatus in said circuit, substantially as set forth.

Structurally, the Fleming tube and its circuit as defined in the claims in suit are identical with those disclosed by Edison. Both have a vacuum globe containing two non-contiguous conductive elements, one susceptible of being heated, the other connected with the first by an outside circuit. Moreover, Fleming's claim 1 is patterned after the cited Edison claim 5, and structurally reads directly on the Edison disclosure.[1] Consequently the court below correctly held that these features of the Fleming patent cannot be treated as his discovery (Finding LXXII; I R. 67), and the plaintiff does not seriously dispute this.

---

[1] See p. 108, *supra*.

(b) The Edison Tube as a Rectifier of Alternating Current

Edison disclosed that his two-electrode tube operated to pass current across the vacuous space within the tube between plate and filament. Fleming described the use of a substantially similar device to rectify alternating currents of Hertzian-wave frequency. But there was no novelty in such use, for it had been disclosed not only by others but by Fleming himself, years before the invention date of the patent here involved.

On January 9, 1890, more than ten years before he filed his application for that patent, Fleming acknowledged in a paper read before the Royal Society of London:

> It has been known for some time that if a platinum plate or wire is sealed through the glass bulb of an ordinary carbon filament incandescent lamp, this metallic plate being quite out of contact with the carbon conductor, a sensitive galvanometer connected between this insulated metal plate enclosed in the vacuum and the external *positive* electrode of the lamp indicates a current of some milliamperes passing through it when the lamp is set in action but the same instrument when connected between the *negative* electrode of the lamp and the insulated metal plate indicates no sensible current. This phenomenon in carbon incandescence lamps was first observed by Mr. Edison, in 1884, and further ex-

amined by Mr. W. H. Preece, in 1885. (Ex. I-1, IV R. 3413, 3414).

This 1890 paper further pointed out that the vacuous space is "unilateral" in its conductivity, that is, it permits current to flow from the hot carbon filament to the cooler metal plate "but not in the reverse direction" (IV R. 3415, 3417), and noted the ability of the tube to act as a rectifier of alternating current:

> When the lamp is actuated by an *alternating* current a *continuous* current is found flowing through a galvanometer, connected between the insulated plate and *either* terminal of the lamp. The direction of current through the galvanometer is such as to show that negative electricity is flowing from the plate through the galvanometer to the lamp terminal (IV R. 3416).

The then popular conception was that electricity flowed from the positive pole to the negative pole, but Edison's discovery made it necessary to revise this conception, and to accept the phenomenon of electricity's passing from negative pole to positive pole. Fleming's 1890 paper noted that it is *negative* electricity which is flowing from negative pole to positive pole, but emphasized that even this had been part of general *scientific* knowledge, as follows:

> The effect of heating the negative electrode in facilitating discharge through

vacuous spaces had previously been described by W. Hittorf ("Annalen der Physik und Chemie," Vol. 21, 1884, p. 90–139), and it is abundantly confirmed by the above experiments. We may say that a vacuous space bounded by two electrodes—one incandescent, and the other cold—possesses a unilateral conductivity for electric discharge when these electrodes are within a distance of the mean free path of projection of the molecules which the impressed electro-motive force can detach and send off from the hot negative electrode.

This unilateral conductivity of vacuous spaces having unequally heated electrodes has been examined by MM. Elster and Geitel (see "Wiedemann's Annalen," Vol. 38, 1889, Vol. 24, 1885, p. 83), who in experiments of various kinds have demonstrated that when an electric discharge across a vacuous space takes place from a carbon conductor to another electrode, the discharge takes place at lower electromotive force when the carbon conductor is the negative electrode and is rendered incandescent (IV R. 3421–3423).[5]

[5] Other papers on the same subject published by Fleming years prior to November 1904, expounded and elaborated upon this phenomenon. Proceedings of Royal Institution of Great Britain, February 14, 1896 (Ex. J–1, IV R. 3425); London Electrician, February 21 and 28, 1896 (Ex. K–1, IV R. 3443; Ex. L–1, V R. 3447; Physical Society of London, March 27, 1896 (Ex. N–1, V R. 3466).

Fleming's reference in his 1890 papers to the unilateral conductivity of the vacuous space between filament and electrode, and the consequent ability of the tube to derive a continuous current from an alternating current, recognized the Edison tube to be a rectifier of alternating current in general terms; and this knowledge entered the public domain by publication.[*]

Rectification was the result of unilateral conductivity for the following reason: If to the tube with its external circuit from filament to plate, there be delivered an alternating current, the unilateral conductivity of the internal space between filament and plate would allow the flow of current between them only during those parts of the alternating current cycles when the alternating current is of such direction that the plate is rendered positive relative to the body of the filament. Thus the alternating current applied to the tube flows in the plate to filament circuit of the tube only as a pulsating continuous or direct current made up of alternate half cycles of the alternating current having a common direction of flow. Thus, the function known as rectification of the alternating current is performed.

---

[*] It is fundamental in patent law that an inventor's own prior publication made more than two years (now one year) before his application for a patent is a bar to any claims of the patent applicable to the published disclosure. Rev. Stat. §§ 4886, 4920; 35 U. S. C. § 31, 69. *Wianer* v. *Meccano, Ltd.*, 246 Fed. 663 (C. C. A. 6); *Mailhahn* v. *R. C. A. Victor Co.*, 89 F. (2) 317 (C. C. A. 4).

This mode of operation was a matter of general knowledge before the earliest date for Fleming's patent. It was specifically explained in a paper delivered by Fleming in 1896 (Ex. N–1, Experiment No. 27, V R. 3466, 3511). On February 17, 1897, at a meeting of the American Institute of Electrical Engineers in New York, Dr. Clark Howell described and illustrated the "Edison effect" in detail and mentioned that when the Edison tube was actuated by alternating current, unidirectional current resulted (Ex. M–1, V R. 3459, 3462); and in discussing Dr. Howell's paper, Dr. Kennelly specifically drew attention to this fact (V R. 3465).

In 1903, the deValbreuze patent, as we shall show, employed the two-electrode tube as a rectifier of alternating current (of Hertzian frequencies). And in October 1904, before the earliest date attributable to Fleming's patent, Wehnelt also disclosed the specific arrangement employed by Fleming, in which a source of alternating current was connected between the hot filament and cold electrode of a vacuum tube and was rectified by the unidirectional conductivity of the tube (Ex. O–1, P–1, V R. 3515). Indeed, Wehnelt improved the sensitivity of the Edison tube by substituting a better filament, capable of emitting a greatly increased flow of electrons.

Edison and Fleming employed carbon filaments in their vacuum tubes and heated the filament by

passing current through it. Since carbon is a poor electron emitter, and since the value of the current flowing between plate and filament depends upon a large electron flow from the filament, the current passing through the vacuous space in these tubes was not large, i. e., the sensitivity of the tube was small. The improvement in this respect, developed by Dr. Wehnelt and published in his paper of October 1904, consisted of a metal-oxide coating of the filament in Edison's two-electrode tube. Such oxide coating, when heated by the filament, emitted an enormously increased supply of electrons, greatly increasing the conductivity of the vacuous space.[24] In his article Wehnelt illustrated the application of the oxide-coated filament to a two-electrode tube and the use of the tube as a rectifier of alternating currents (Ex. O–1, translated in Ex. P–1; V R. 3515–3518). After describing the unidirectional conductivity of the tube in terms of the voltages necessary to force current through it between plate and filament, Wehnelt's article described the exact manner of connecting and rectifying the alternating current employed by Fleming (V R. 3516–3517), as follows:

Emission of Negative Ions by Incandescing Metallic Oxid. A glass tube *K* (Fig.

[24] Wehnelt's paper in the *Annalen der Physik* set forth in great detail the results of numerous tests on filaments coated with oxides of the alkaline earth metals barium, calcium, and strontium, and showed the enormously increased emission obtained therefrom (Ex. Q–1, translated in Ex. R–1; referred to in Ex. P–1, V R. 3515).

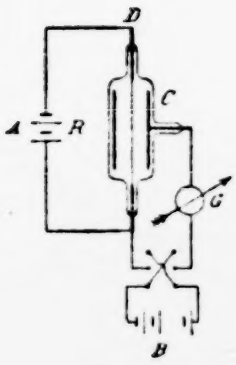


Fig. 1.

1), exhausted to a moderate extent, contains a brass cylinder C in the axis of which there is situated a thin platinum wire D covered with CaO. The wire can be heated to high temperatures by the current of two accumulators A. If I connect the wire D with the one pole, the cylinder C through a galvanometer G with the other pole, of a source of current B, then there only flows a current through the tube if D is connected with the negative pole of B. The experiment shows consequently that only negative ions are emitted from the incandescing oxid. * * *

Application of Discharge Tubes with Glowing Metal Oxid Cathodes in Practice. If in an exhausted discharge tube R (Fig. 4)[2] we push one or several metallic electrodes A close to the glowing metallic oxid electrode K (platinum sheet P covered with

[2] The cathode K is assumed to be turned 90° as regards the plane of the picture.

Fig. 4.

the CaO) then the discharge potential, if *A* is anode and *K* is cathode, amounts to only about twenty volts. If we reverse the direction of currents so that now *A* is cathode and *K* is anode, the discharge potential now amounts to some thousands of volts, since under deep pressures the cathode drop on metals takes on exceedingly high values. *If, therefore, we connect the electrodes A and K with an alternating source of current, the potential of which lies below the value which the cathode drop on the metallic electrode A has, then the tube acts as an ELECTRIC VALVE, in that it allows to pass through only one phase of the alternating current. The tube (Fig. 4) can consequently serve for the purpose of transforming alternating current into pulsating direct current.* [Italics supplied.]

It was therefore well known prior to Fleming, as was correctly held by the court below (Findings LXXI and LXXII; I R. 66–67), that the two-electrode vacuum tube shown by Edison

operated as a rectifier to receive alternating current and transform it into direct current.

(c) The Two-Electrode Vacuum Tube as a Wireless Detector

The knowledge in the prior art concerning the use of the uni-directional two-electrode tube to rectify alternating currents was not restricted to the rectification of low frequency current. Not only was its applicability to high frequency alternating currents a natural corollary of the tube's mode of operation with which the art was familiar; but its actual use to rectify high frequency currents for wireless detection[58] had been fully disclosed in the art antedating Fleming's patent.

To one skilled in the art, it was implicit in the earlier teachings concerning the Edison effect that the two-electrode tube would serve as a rectifying device of waves of wireless frequencies.

---

[58] Many forms of detectors were known for detecting (or recognizing) that a signal has been received in a system of wireless telegraphy (see 1894 publication of Lodge, V R. 3876-3877). When the incoming signal energy was employed merely to "trigger" (i. e., close) a local battery circuit, as with the coherer (described at pp. 40-41, *supra*), the signal current could be employed without change, since the local battery supplied the pulsations of direct current for operating the indicator. When it was desired, however, to use the incoming signal current itself to actuate the indicator, the alternating current of the signal had to be rectified, i. e., converted into pulsations of direct current to which the indicator would respond, as was disclosed by de Valbreuze in 1903, for example (Ex. A-2, translated in Ex. B-2, V R. 3540-3547; Finding LXX, I R. 65-66).

None of the detailed treatises by Fleming, Howell, Kennelly and Wehnelt, discussing the rectifying action of the two-electrode tube, made any suggestion that this phenomena was dependent in any manner on the frequency of the alternating current. On the contrary, all treated it as applicable regardless of frequency (Ex. I–1, IV R. 3413; Ex. M–1; V R. 3459; Ex. P–1, V R. 3515). Indeed the work of J. J. Thompson, O. W. Richardson, and others in the years immediately prior to 1904, had identified the theory and operation of the Edison effect with the now familiar electron theory,[28] and had thus made obvious the potentialities of the two-electrode rectifier in the high-frequency field.[29] As the court below properly found, Thompson's and Richardson's experiments established that the incandescent filament of the Edison tube served to emit electrons, that the mass of these electrons was only 1 2000 of that of a hydrogen atom, and that their speed was so enormously high that the electron discharge device of Edison would operate practically without inertia.[30]

[28] XLVI Philosophical Magazine (1898), 328 (Ex. S–1); XLVIII *Ibid.* (1899), 547 (Ex. T–1); V *Ibid.* (1903), 354, 429 (Ex. U–1, Z–1); IX Proceedings Cambridge Philosophical Society (1897), 244, 333 (Ex. X–1, Y–1); XI *Ibid.* (1901), 286 (Ex. V–1); XI Philosophical Transactions Royal Society (1903), 497 (Ex. W–1), I R. 680, 681.

[29] This is well explained by Miller, I R. 671.

[30] Because the electron is of infinitesimal weight, it requires only an infinitesimal interval of time to start and stop its flow, and the oscillatory period of even the highest frequency wireless wave is so extremely long, by comparison,

Consequently, it was to be expected that Edison's device would operate under both high and low frequencies in exactly the same way to pass the current in one direction between the filament and plate of the tube. As stated by the expert witness, Dr. Miller, in view of this knowledge in 1903 "any scientist at that date would have known it would so operate from his reading of the literature of the art. Indeed, he would have no reason to think otherwise" (I R. 678–684, at 682). That none in fact thought otherwise is clearly shown by the circumstances that despite exhaustive study of the phenomenon, no one suggested that the frequency would make any difference in the rectifying action of the device.[20]

But apart from these indications of the inherent efficacy of the Edison device as a rectifier of high frequency oscillations, which to the learned were unmistakable, there was specific disclosure by de Valbreuze of the application to wireless of the two-electrode vacuum tube. In his French patent No. 328,527 issued in 1903 (Ex. A–2, V R. 3540, translated in Ex. B–2, V R. 3547), de Valbreuze disclosed that the electronic vacuum tube would operate as a rectifier-detector of radio fre-

---

that the electron flow will respond at once to such a wave and will even be regulated by minute fractions of a single high frequency cycle.

[20] Plaintiff itself, in demonstrating the Fleming device in the case of *Marconi Wireless Telegraph Company of America* v. *De Forest Radio Telegraph & Telephone Co.* 243 Fed. 551 (C. C. A. 2), used low frequency current (I R. 682).

quency currents, and he showed its use in the same circuit arrangement used by Wehnelt and by Fleming. The court below so found (Finding LXX, I R. 65–66), and the correctness of this finding is conceded by plaintiff (Pl. Brief, pp. 64–65). The text of the de Valbrueze patent read in part as follows:

> As receiver there is employed an apparatus which allows of re-transforming the alternating current into a continuous current, actuating a relay. For that recourse is had to apparatus called electric valves, placed as described hereinafter, and diagrammatically represented by Fig. 2. (V R. 3550).[*]

Claim 2 of the de Valbreuze patent repeaaed that his device would transform high frequency currents:

> The use of a device called an electric valve formed by a vacuum tube, or of several similar valves combined together, in order to transform into currents always in the same direction, the alternating currents of very rapid frequency transmitted to the receiving apparatus (V R. 3550).

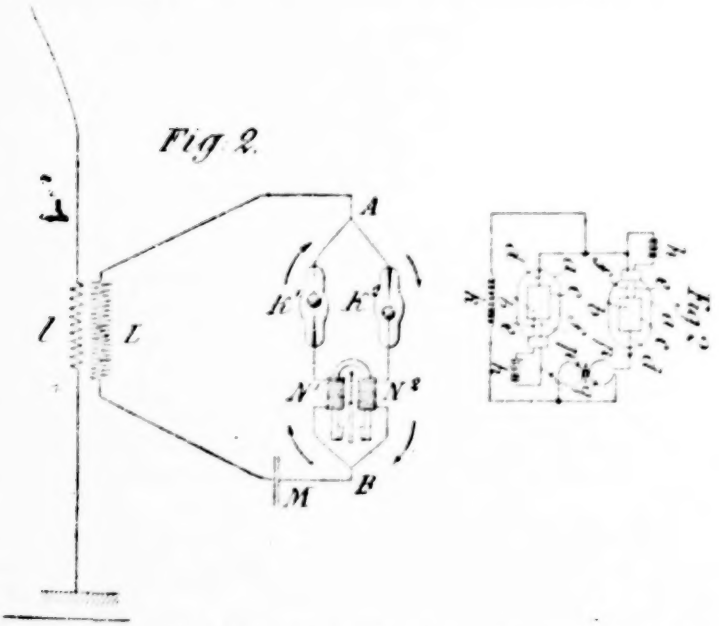
And Figure 2 of the de Valbreuze patent showed two vacuum tubes K' and K'' in reversed position,

---

[*] Wehnelt also called his two-element tube an "electric valve" (see p. 129, *supra*), and so did Fleming in his specification (IV R. 2601, line 19, p. 107, *supra*). That is now a commonly used term to designate the two-element vacuum tube rectifier of the Edison-Wehnelt-de Valbreuze-Fleming type.

so that current would flow through one or the other of the valves during each half-cycle of the alternation of current.[62] The two half-wave rectifiers so connected operated as a full-wave rectifier, corresponding exactly to the two half-wave rectifiers shown by Fleming in Figure 2 of his patent. The identity of arrangement and operation is obvious from the following reproductions of Figure 2 of de Valbreuse and Figure 2 of the Fleming patent (the latter turned on its side to correspond with the orientation of the former):

de Valbreuse Patent *Fleming Patent*



[62] This was also known to Wehnelt. In his 1904 publication he stated: "By using the well known Graetz system of connection, both phases of the alternating current can be utilized" (Ex. O-1, translated in Ex. D 1; V R. 3518).

Thus prior to November 1904—Fleming's earliest date—it was well known that the rectifier vacuum tube called an electric valve would be suitable for use as a radio detector of high frequency waves, and it had been so applied by de Valbreuze.

The unidirectional operation of the vacuum tube of de Valbreuze, like that of Edison and Fleming, depends upon heating the cathode or filamentary element to cause the current of electrons to flow from it to the anode or plate. The cathode in the de Valbreuze tube, being a fine point, has a greater potential and current density per cm than the large surface of his anode. Hence, in an alternating current circuit, it heats more and liberates more electrons than does the anode, and therefore exhibits the unilateral conductivity which makes it a rectifier. The only difference between the de Valbreuze vacuum tube and that of Edison and Fleming is that in the de Valbreuze tube the cathode was heated partly by electric current and partly by bombardment by the ions derived from the residual gas in the tube, whereas in the Edison and Fleming tube the cathode was heated practically entirely by current. But this involved no inventive difference. It was well understood by the art as early as 1896 that the heating of the cathode to cause unidirectional current flow could be accomplished in several ways. Fleming himself suggested that the cath-

ode of a two-electrode tube be heated by concentrating on it the rays of a lamp, which Professor Thompson characterized as equivalent to heating it electrically (Ex. N-1, V R. 3514),[93] Edison had already taught the art that the sensitiveness of the rectifier—i. e., the strength of the rectified current—would be increased if the temperature of the cathode were increased (see pp. 110–112, *supra*),[94] and Fleming, in his patented device, utilized the identical mode shown by Edison—the local battery circuit—to heat the cathode. This was not claimed, and obviously could not have been claimed, as the element of novelty in Fleming's patent.

3. *Fleming's alleged invention was not entitled to patent in view of the prior art*

In view of the state of the art at the time of Fleming's alleged invention (November 16, 1904), it is clear that plaintiff cannot assert a patentable right to any of the basic elements of Fleming's disclosed structure. Comparison between the essential features of the Fleming patent and the most pertinent prior art, as presented in

[93] In addition to the modes of heating referred to, Wehnelt had used a speck of calcium oxide as his cathode and heated it by contact with an electrically heated member (Ex. O 1, translated in Ex. P 1, V R. 3515), and this is the mode employed in heating the cathode in practically all of the "heater type" or "unipotential-cathode" tubes so widely used today.

[94] Fleming's 1890 papers acknowledged that Hittorf had also recognized this fact (see p. 115, *supra*).

TABLE 2

tabular form in the accompanying Table 2, will disclose the virtual identity between Fleming's device and the prior art devices, in structure, operation, and result. Such comparison will similarly establish that claims 1 and 37 of the Fleming patent, even after the disclaimer, did not comply with the requirement of the patent laws that they specifically point out the particular contribution, if any, which the patentee made; and since these claims assert a right to more than Fleming was entitled to claim, they were invalid.[3]

It is apparent, therefore, that at the time of Fleming's alleged invention, the art was already conversant with the two-electrode vacuum tube of which the cathode electrode—the electron emitter—was heated in various ways to increase its emission of electrons. It was also known at that time that such a tube would have unilateral conductivity in the vacuous space between the electrodes, making it a rectifier of alternating current; that the tube would operate at high as well as at low frequencies; and that the two-electrode vacuum tube rectifier was useful as a detector in wireless apparatus. Fleming's use of the unidirectional conductivity of the Edison two-element tube to rectify incoming alternating current was consequently nothing more than the noninventive application of prior disclosures. And his use of

[3] Cf. *General Electric Co.* v. *Wabash Appliance Corp.*, 304 U. S. 364, 372.

the current thus rectified to operate an indicator in the same circuit was precisely what Edison and Wehnelt had done earlier.

Plaintiff purports to distinguish Fleming's alleged invention from the Edison-Wehnelt rectifier arrangement on the ground that Fleming showed a use of his device with currents alternating at frequencies of the order of Hertzian waves. The vagueness and uncertainty of this differentiation was enough to condemn it;[65a] but in any event, such use is entirely without novelty, for the usefulness of the tube to rectify Hertzian waves was easily discernable and indeed squarely disclosed in the art. The two-electrode tube of Edison and Wehnelt was known to be a rectifier of alternating currents without regard to frequency, and by its very electronic character was capable of rectifying the entire range of alternating current frequencies, from the upper limit of Hertzian waves to frequencies corresponding to an occasional reversal of a battery current input. The use of a rectifier to detect wireless waves was old in the art, and deValbreuze had disclosed use of a two-electrode tube for this purpose. That the battery heated tube was a more sensitive rectifier than that of deValbreuze is without moment, for the Edison

[65a] The Hertzian waves, as pointed out by Lodge (see pp. 36-37, *supra*), range from 186 cycles to 900,000,000 cycles; while audible frequencies range from 50 cycles to about 15,000 cycles. There is no dividing line between these frequencies, nor is either range sharply defined.

patent, Fleming in his 1890 papers, and many others had recognized that the sensitiveness of the two-electrode vacuum tube rectifier was improved by increasing the temperature of the cathode to full incandescence. And while the battery heated filamentary cathode of the Edison tube used by Fleming may have been a better electron emitter than deVallbreuze's fine-point cathode heated by the Hertzian waves,* such battery heating of the filament to increase its emission was known prior to Fleming. Consequently, none of these features can be claimed as the novelty in Fleming's device, as the court below properly found (Finding LXXII; I R. 67).

Even if Fleming's claims in suit (p. 108, *supra*) were limited to battery-heating of the filament, instead of purporting to cover all means for heating it, at best he either (1) used the well-known alternating current rectifier shown by Edison or Wehnelt to rectify high-frequency alternating

* Fleming himself, in his patent, acknowledged that when strong Hertzian waves are received, their alternating current will itself be sufficient to heat the filament to incandescence. Since it is this same current which flows through and heats the fine point of the deVallbreuze tube—which will be further heated by ionic bombardment—this filamentary point of deVallbreuze will be heated at least as much as Fleming's filament under the same conditions. Fleming's claims in suit are not limited to battery heating of the filament but cover as well the acknowledged alternative in which the current of the received signal heats the filament; hence, these claims cover and are directly anticipated by the deVallbreuze arrangement alone.

currents in circumstances not specifically shown by them, as found by the court below (Finding LXXIII, I R. 68), or (2) substituted the more sensitive rectifier of Edison or Wehnelt for the analogous rectifier of deValbreuze, who had already informed the art that such a device was desirable for the rectification of wireless waves. Whichever Fleming did, he produced no result which was not obvious (III R. 2139). Even if deValbreuze's disclosures could be disregarded, Fleming's contribution would amount to no more than a new use of an old device, as the court below found (Finding LXXIII; I R. 68), and since no new or unexpected operation was imparted to the Edison tube by using it to rectify high-frequency instead of low-frequency currents, the "new use" cannot support a patent monopoly.[1] Fleming's structure may also be characterized as the result of varying the degree or extent of operation of a disclosed process or device, which this Court has held does not attain the dignity of invention.[2] It was in fact to be expected from "observations of common experience" that once the feasibility was established of using the two-

---

[2] *Thompson-Starrett Co. v. Otis Co.*, 271 U. S. 80; *Wells Co. v. Ford Motor Co.*, 263 U. S. 445, 451; *DeForest Radio Co. v. General Electric Co.*, 283 U. S. 664.

electrode tube to rectify alternating current, those familiar with the field "would seek to make use of known methods and appliances" to rectify wireless waves. (*cf. Concrete Appliances Co.* v. *Gomery*, 269 U. S. 177, 184); and once the rectifying properties of the two-element tube became known it was not long before the art sought to make use of the tube for alternating currents, such as wireless oscillations, as for example the two-electrode vacuum-tube rectifier which deValbreuze employed as a wireless detector in his patent.

Even the criterion utilized in cases of doubtful validity—the commercial success of the alleged invention—is not met by Fleming's device. The announcement of the Edison two-electrode tube excited world-wide interest, and scientists everywhere investigated it thoroughly (see pp. 113–122, *supra*), while the disclosure by Fleming of its use with high-frequency current evoked little comment. Measured by results and enduring use, comparison likewise favors Edison. The Fleming use was a fugitive one; a few were used experimentally in receiving stations, and later a number were sent to various Marconi receiving stations. But wherever they were installed, the sets were provided with crystal rectifier-detectors for alternate use (Finding LXVII, I R. 63), and within a year or two substantially all of the stations had discarded the Fleming tubes and were using crystals ex-

clusively (II R. 1374)." By contrast, the Edison tube-Wehnelt circuit is in large use today. Nearly every household A. C. radio set contains an Edison-Wehnelt rectifier operating to transform the low-frequency house lighting alternating current into direct current to operate or energize the tubes used for high-frequency uses."

In summary, the evidentiary findings of the court below concerning the disclosures in the prior art of the entire substance of the Fleming

---

" To argue that the deVallereuze diode was not sufficiently sensitive as a detector does not distinguish it from Fleming's disclosure, for his device was also insensitive. Even with the powerful Marconi interests behind it, the Fleming valve made no lasting impression on the art. It simply echoed deVallereuze's teaching that a rectifier was a desirable detector. The Fleming rectifier, like that of deVallereuze, passed from the scene in the face of the better rectifier-detector, the crystal. And all of them finally made way for the DeForest three electrode tube which, as a detector, substituted modulation amplifying relay action for rectification. The function of rectification in nearly every modern radio set is limited to conversion of the house lighting alternating current into direct current to operate the tubes; and this is performed by an Edison Wehnelt rectifier.

" As will be shown hereinafter (pp. 169-173), the decision in *Marconi Wireless Telegraph Co. of America* v. *DeForest Radio Telephone & Telegraph Co.*, 236 Fed. 942 (S. D. N. Y.), affirmed, 245 Fed. 551 (C. C. A. 2), is not entitled to any weight in the present case. Although holding that the Fleming patent here involved was valid and was infringed by DeForest's three-electrode tubes, for collateral reasons both parties had agreed in the district court and the circuit court of appeals that the two electrode and the three electrode device were essentially alike, thus eliminating any controversy on the point crucial to this case.

device are adequately sustained by the evidence, and would have justified an ultimate finding of invalidity for lack of invention. This Court may itself make such a finding as a basis for affirming the judgment below. Cf. *Stelos Co.* v. *Hosiery Motor Mend Co.*, 295 U. S. 237.

4. *The patent is invalid because of improper disclaimer*

There is no doubt that the Fleming patent, as issued on November 7, 1905, was partially invalid at least, for, as the court below correctly found (Finding LXXI, I R. 66-67), claim 1 of the patent, before the 1915 disclaimer, applied word for word to the earlier Edison patent and also read upon the arrangements disclosed in the 1890 and 1897 publications. Under settled law, such partial invalidity would defeat the entire patent unless the invalid portion were properly and seasonably disclaimed.[7] A disclaimer was filed in 1915, ten years after the patent issued, which the court below held constituted unreasonable delay invalidating both the disclaimer and the patent (I R. 106). This conclusion, which we believe was proper, is further sustainable upon the independent ground that the subject matter of the disclaimer was improper. Both grounds, which were urged by defendant in the court below, are

[7] Revised Statutes, §§ 4917, 4922; 35 U. S. C. §§ 65, 71; *Easton* v. *Simon, Ascher & Co.*, 282 U. S. 445, 452.

here advanced as additional grounds for affirmance of the judgment as to the Fleming patent. *Stelos v. Motor Metal Hosiery Corp.*, 295 U. S. 237.

(a) Unreasonable Delay in Disclaiming

For some ten years after its issuance, the Fleming patent was held out to the public as a monopoly covering its claimed features, including even Edison's device of a two-element electronic vacuum tube. Then on November 17, 1915, the plaintiff as assignee of Fleming filed a disclaimer in which it disclaimed the combinations of claim 1 and other claims—

> except as the same are used in connection with high frequency alternating electric currents or electric oscillations of the order employed in Hertzian wave transmission.[*]

The invalidity of the disclaimer was urged by the defendant before the court below, and although the court made no findings of fact on the issue, it held in its opinion that there had been unreasonable delay in disclaiming. The court referred to Fleming's original claim of the use of the two-electrode tube to rectify both low and high frequencies, and said (1 R. 106):

> In stating this feature in his patent specification as 'new and patentable, Fleming must have known that he was making a

[*] This disclaimer was filed at a time when plaintiff was about to sue a competitor (Pl. Brief, p. 70).

> claim that could not be sustained. There could have been no inadvertance in making this statement, and this matter alone would seem to be sufficient to render the Fleming patent invalid. True, he entered a disclaimer later, but the statutes which give relief where invention has been wrongfully claimed do so only on the condition that the inventor has not unreasonably neglected or delayed to enter the disclaimer. In the case at bar the disclaimer was not entered until eleven years after the patent had been taken out and long after other inventors had discovered other and different methods of making use of the Edison device without claiming to have invented it. We think that if ever there was a case of unreasonable delay in making the disclaimer it is presented in what is now before us and that the Fleming patent must be held invalid for that reason.

This holding is in full accord with both the record and the law. The record leaves no room for doubt that Fleming had full knowledge of Edison's work before he filed his patent application, for he had investigated it thoroughly (I R. 105–106). Yet he drew the specification for his patent to include Edison's vacuum tube whether used with current "of low frequency or of high frequency" (Ex. 22, IV R. 2601, lines 30–33) and stated that "the device may be used for rectifying either high frequency or low frequency

alternating currents of electrical oscillations" (*id.*, lines 97–102). His claim 1 was patterned closely upon Edison's claim 5, covering Edison's device without change (*cf. id.*, lines 125–129, with Ex. J., IV R. 3298, lines 50–54).

Since the record shows that Fleming's specification and claim 1 covered the Edison device and that Fleming had full knowledge of Edison's work, the court's conclusion that "there could have been no inadvertence" is well founded. *Cf. Euston* v. *Simon, Ascher & Co.*, 282 U. S. 445. At any rate, in view of the conceded delay of more than ten years in filing a disclaimer—covering a period in which the electronic tube was developed—the court's conclusion that there had been unreasonable neglect cannot be said to lack substantial evidence.[7] The unreasonableness of the delay in the circumstances of this case is emphasized by the fact, as found below, that the three-electrode tube had been fully developed and adopted by the United States before the disclaimer was filed (Finding LXXXI, I R. 74).

(b) The subject matter of the disclaimer is improper

The impropriety of the subject matter of the disclaimer constitutes an additional and inde-

[7] The absence of findings of fact on the matter of delay is not fatal, in view of the alternative ground (anticipation) relied upon below for the conclusion of invalidity, *cf. Stalos* v. *Motor-Metal Hosiery Corp.*, 295 U. S. 237.

pendent ground to sustain the conclusion below as to its invalidity. This was urged below, but not passed upon because of the court's conclusion that "the patent is void in any event for failure to make disclaimer within a reasonable time" (I R. 107).

A disclaimer intended to save a patent from invalidity because of erroneous or excessive claims, "is usually and properly employed" to surrender a separate claim "or some other distinct and separable matter, which can be excinded without mutilating or changing what is left standing." *Hailes* v. *Albany Stove Co.*, 123 U. S. 582, 587.[*] Since a disclaimer may not "change the character of the claimed invention" (*Milcor Steel Co.* v. *George A. Fuller Co.*, 316 U. S. 143 (1942)), and since every disclaimer "which does not surrender the whole claim, must add a new element" to it—which is not permissible—the surrender of a separable portion of the patent is an essential of a valid disclaimer. *Milcor Steel Co.* v. *George A.*

[*] The essence of a valid disclaimer lies in "disclaiming a part separated in the patent itself" (*Strause Gas Iron Co.* v. *Crane Co.*, 235 Fed. 126 (C. C. A. 2); *Corn Products Refining Co.* v. *Penick & Ford*, 63 F. (2) 26, 30 (C. C. A. 7)), or a part "distinguishable on the face of the specification" (*Grasselli Chemical Co.* v. *National Aniline Co.*, 26 F. (2) 305, 310 (C. C. A. 2)), as opposed to something comprehended in the "general language" of the patent. *Strause Gas Iron Co.* v. *Crane Co.*, supra; *Albany Steam Trap Co.* v. *Worthington*, 79 Fed. 966 (C. C. A. 2); *Simplex Ry. Appliance Co.* v. *Pressed Steel Car Co.*, 189 Fed. 70 (C. C. A. 2).

Fuller Co., 122 F. (2d) 292 (C. C. A. 2), affirmed 316 U. S. 143.

Tested by these rules, plaintiff's disclaimer under the Fleming patent was invalid because it added a new element thereto. The disclaimer made no change in the structure or mode of operation of the invention.[1] It sought only to change claim 1 to restrict the operation of the means already disclosed to high frequency current only instead of either high or low frequency current. The disclaimer thus added a new element, i. e., a source of high frequency alternating current, which before the disclaimer had expressly been treated as immaterial. The effect was the same as if the claim had been amended by adding a requirement not theretofore mentioned, such as "use of the disclosed structure in combination with a source of high-frequency current." This operated to "change the character of the claimed invention" and was therefore unauthorized by the disclaimer statute. *Milcor Steel Co.* v. *George A. Fuller Co.*, 316 U. S. 143.

It is submitted that upon the evidentiary findings below and upon the authorities here cited, an

---

[1] Compare cases upholding disclaimers changing the structural features of an invention, for example *Carnegie Steel Co.* v. *Cambria Iron Co.*, 185 U. S. 403.

[2] Compare the attempted disclaimer of one chemical substance under a broad general claim covering a number of chemical substances, a form of disclaimer held void in *Grasselli Chemical Co.* v. *National Aniline Co.*, 26 F. (2) 105 (C. C. A. 2).

ultimate finding of invalidity of the disclaimer is clearly justified because of the impropriety of its subject matter. The ineffectiveness of the disclaimer for either this reason or because of unreasonable delay in filing invalidates the Fleming patent.

POINT IV

THE COURT BELOW PROPERLY HELD THE FLEMING PATENT NOT INFRINGED

The judgment below holding the Fleming patent not infringed applied to three types of three-electrode vacuum tubes which plaintiff charged as infringements: (1) the relay-detector, (2) the amplifier, and (3) the oscillator. After making detailed evidentiary findings as to the structure, mode of operation and result of Fleming's patented device and of the three-electrode tubes (triodes) used by the defendant, the court found as an ultimate fact that the triodes differed substantially from Fleming's tube in each of these essentials (Findings LXXV–LXXIX, I R. 69–73). We shall show that this conclusion is proper as to each type of triode used by defendant.

1. *The DeForest Three-Electrode Tube*

Prior to 1906, several vacuum tube devices were known to the art for use with wireless equipment. In the receiver, the Z under "Trigger Tube" was used (in which the received oscillations precipitated a discharge through the tube from an aux-

iliary battery) and the two-electrode tube of Edison-deVallbreuze-Fleming was employed as a rectifier (V R. 3876–3877). In the transmitter, the Hewitt gas-filled tube was used as a generator of continuous waves, as had been disclosed by de Valbreuze (Ex. A–2, Fig. 1, V R. 3544, 3549). The only amplifier which had been proposed in the art prior to 1906 was the "negative resistance" characteristic of the gas-filled Hewitt tube which produced amplification but was unsatisfactory (Ex. O, IV R. 3320; Ex. P, IV R. 3323). All these tubes were of the two-element or diode variety.[1] In 1906, Dr. Lee DeForest invented the three-electrode tube and obtained United States patent No. 879,532 therefor on February 18, 1908 (Ex. K, IV R. 3299), upon application filed January 29, 1907.

This tube and its circuits differ in structure from the prior devices in having a third electrode known as a grid (consisting of a mesh or widely-spaced turns of wire) interposed between but not touching the filamentary cathode and the plate or anode, the grid being connected to the filament outside the tube by a circuit entirely independent of the plate circuit, and the incoming alternating current being connected in this independent grid circuit. The plate circuit of the tube is connected

[1] Except possibly the Zehnder Trigger Tube (V R. 3876, 3877.

permanently to the positive end of a high voltage (direct current) battery known as a *B* battery, while the filament of the tube is connected permanently to the negative end of that battery. The filament is heated to incandescence by current from a local battery circuit (the *A* battery). By this arrangement the potential of the plate is always kept positive relative to that of the filament, as in the original Edison circuit, so that the stream of electrons emitted by the hot (negatively charged) filament will be greatly attracted by the positively charged plate. As a result the local direct current derived from the *B* battery passes continuously through the filament-to-plate circuit.

The incoming alternating current signal is received in the grid circuit, and changes the voltage on the grid, according to the strength and characteristic of the signal, making the grid alternately more positive and more negative than its initial condition. When the grid is negative, it tends to repel or impede the flow of electrons from the adjacent filament; when the grid is positive, it tends to increase and accelerate the flow, but being placed closer to the filament than is the plate, the grid exerts a more powerful effect on the flow of electrons than does the plate, so that a negative charge on the nearby grid can counter-

act or diminish the effect on the electrons near the filament of a much higher positive charge on the more distant plate. However, since the area of the openings between the wires of the grid is much greater than the area presented by the grid wires themselves, most of the electron stream from the filament, when not repelled by a negative charge on the grid, passes through the openings in the grid and thence to the positive plate. It was thus De Forest's discovery that a small change in potential on the grid would produce, by relay action, a disproportionately large change of the direct current in the plate circuit, and the direct current in the filament-to plate circuit, thus modified in proportion to the change of potential on the grid, would operate the indicator or detector in the plate circuit.

The ability of the relatively weak incoming signal potential on the grid to affect with proportionate variations the much more powerful current in the filament to plate circuit gives the tube its amplifying characteristic. The powerful *B* battery, which keeps the plate highly positively charged relative to the filament and can supply a large number of electrons to the filament to be emitted by it, provides a great deal of power for driving current through the plate circuit. As a

result the grid acts like a relay or throttle, whereby the small power input of the received oscillations controls the much greater power of the plate circuit. Since the output power in the plate circuit is much greater than, but faithfully controlled by, the lesser power in the input circuit, the input varied potential of the grid, operating the tube as a relay, is reproduced in facsimile, but much amplified, in the local current flowing in the plate circuit.

The amplifying powers of the triode of course operate equally well with high or low frequency variations of the grid potential. Moreover, the faculty of amplification enables the tube also to act as a self-sustaining generator of oscillations in a wireless transmitter. When so utilized, the triode's function is to generate a continuous oscillation which can be radiated by the antenna. The principle which enables it to generate oscillations may simply be stated. A small change in potential in the grid circuit will cause a much amplified change of current in the plate circuit. Hence, a small part of the plate current change may be utilized to create the grid voltage change necessary again to reproduce the plate current change, and this can go on indefinitely, so that the current in the plate circuit of the tube will maintain continuously an oscillatory variation. If a

sufficient part of the plate current is so used, it changes the potential on the grid sufficiently to reproduce in the plate current a larger variation, the "feed-back" part of which again produces a still larger variation of grid voltage. This action continues until a state of equilibrium is reached, with the plate circuit current oscillating continuously at its maximum value. That portion of the current in the plate circuit which is not being used to change the grid voltage may be applied to an antenna circuit, either directly or through a transformer, and will then be radiated from the antenna as a continuous Hertzian wave.

The same basic principle is employed with the De Forest tube when used in regenerative receivers, except that here the amount of plate current change used to change the potential of the grid is less than that necessary to reproduce the full change in the plate current. Because of this, the current change in the plate circuit dies out quickly unless an augmenting voltage is applied to the grid, as from an incoming signal. When such signal voltage is applied to the grid, a part of the amplified current change which it produces in the plate circuit is used to increase the voltage change on the grid, so that the plate current variation is rendered considerably stronger than if it were

effected only by the signal voltage on the grid. But as soon as the incoming signal ceases, the current variations in the plate circuit die out because the "feed-back" is insufficient to sustain them.

It was this three-electrode tube of DeForest, in the arrangements described above, which the defendant used, and which plaintiff charges constituted infringement of the Fleming patent; defendant used no two-electrode devices. (Finding LXVII; I R. 63).

2. The differences between the triode and the diode are substantial

The findings and conclusion of the court below, that the defendant's three-electrode tubes differed substantially from and hence did not infringe the Fleming device, are sustained not only by the general differences between the two structures in arrangement, operation and effect, but also by the efficacy of DeForest's device for purposes of which the Fleming tube were incapable—that is, amplification and oscillation.

(a) General Structure and Mode of Operation

The difference between Fleming's diode and the DeForest triode used by defendant is illustrated in the following comparative sketches made by

defendent's expert witness, Dr. Miller (Ex. I, IV R. 3283):

Fleming Tube and Circuit — *Defendant's Tube and Circuit*

MILLER DRAWING B

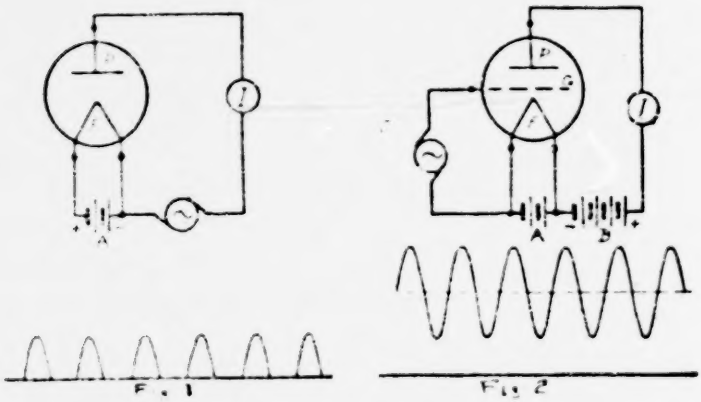

Fig. 1 Fig. 2

The Fleming tube, as we have seen, consists solely of a heated filament and a cold plate, the plate circuit being connected to the *negative* side of the filament so that no steady component of current will flow in the filament-to-plate circuit. The antenna circuit receiving the incoming signal energy is inductively coupled to the plate circuit by a transformer. The incoming signal energy — a high frequency alternating current — is fed directly into the plate circuit by the transformer, alternately rendering the plate positive and negative relative to the filament, and permitting the

current to flow between filament and plate when the latter is positive but not otherwise. The result is a unidirectional flow of a portion of the incoming alternating current, which operates the galvanometer *I* or other signal indicating instrument. The only energy operating the galvanometer is the relatively feeble energy of the signal itself; that energy is in no way augmented. Moreover, since only one-half of the incoming alternating current is permitted to pass through the vacuous space of the tube and through the galvanometer, the actual operating energy is never greater than one-half of the original signal energy.

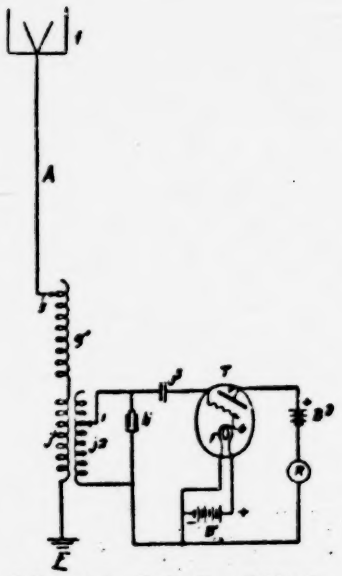
The DeForest three-electrode tube used by defendant, whether as detector, amplifier, or oscillator, comprises not only the two elements of the Edison tube used by Fleming but also a third element, the grid interposed between the filament and plate. The plate is connected permanently to the *positive* end of the local battery so that the electrons emitted by the hot filament will flow continuously to the positively charged plate. Since the plate remains positive, and is never rendered alternately positive and negative (as in Fleming's rectifying circuits), the tube tends *continuously* to pass a local direct current from the battery through the filament-to-plate circuit (which Fleming's tube did only half the time,

when the plate was positive relative to the filament). Being direct, this current does not require rectification. The input energy in the grid circuit is alternating current, but it is utilized solely to change the voltage of the grid, which regulates (by decreasing or increasing) the flow of the direct current from the battery. It is the flow of this locally produced direct current which operates the indicating device in the plate circuit, and not the incoming alternating current energy, as in Fleming's circuit; the DeForest tube uses the incoming energy only to impress different electrical potentials on the grid, thus accelerating or retarding the flow of the local continuous current.

These differences in arrangement, mode of operation and result between Fleming's and DeForest's tube are rendered even more acute when the DeForest device is used for particular purposes.

(b) The Three-Electrode Tube as a Detector

Defendant's three-electrode vacuum tube, when used in a detector circuit, is shown as follows (Ex. 83, I R. 70):



DeForest Audion, Used by Navy (Exhibit 83).

Fleming's tube, as we have shown, functioned solely as a rectifier of alternating current, as did Wehnelt's and Edison's in the circuits known in 1890. The defendant's tubes, however, had either no rectifying action whatever, or only an insignificant and unwanted rectification. There was in fact no need for rectification, since the current operating the indicator device (such as the earphones) was direct current from the local battery, and the incoming alternating current signal was used solely to vary the potential of the grid and thus correspondingly modulate the direct current of the plate circuit, to reproduce in it, by relay action, an amplified replica of the variation in grid potential.

Defendant used two forms of detectors: (1) one in which the desired negative voltage was maintained on the grid by a small battery, known as a *C* battery, and (2) one in which this function was performed by the incoming current passing through a condenser shunted by a very high resistance leakage path.[*]

In neither type is the incoming signal rectified to operate an indicator in the received current circuit, and in neither type does any rectification occur in the filament-to-plate circuit. In the first type (*C* battery-biased), no useful rectification occurs in any circuit. In the second type of detector (grid condenser-grid leak) such slight rectification as does occur is employed, not to operate an indicator, but merely to charge the grid condenser which takes the place of the *C* battery. In all forms of the three-electrode tube, the initial charge on the grid controls the local battery plate current (flowing as the electron stream), and determines whether the grid will give to that current, by relay action, a variation which is a true amplified replica of the incoming signal (as is desired in amplifiers and oscillators), or whether it will give it a variation which is an amplified

[*] The "grid leak" usually employed has a resistance of about 5,000,000 ohms, approximately the resistance of a pencil mark on a piece of paper.

replica of the *modulation* of the incoming signal, as is desired in a detector.

In the *C* battery detector, the grid is so initially charged by the *C* battery that it initially cuts down the plate current to a low value. Thus when it is alternately made more positive and more negative by the incoming signal, by its relay action on the electron stream, it alternately tends to allow large increases and to cause small decreases of the plate current from its initial value. These attempted variations of the plate current during the interval of a signal, when they are passed through a choking device (as a galvanometer, a telephone receiver or an iron-core transformer), are averaged up by such choking device. Such averaging of the large increases and small decreases in the current yields a net increase of current during the interval of a signal, such increase being proportional to the amplitude or strength of the signal. As the amplitude or strength of the signal is its intelligence carrying modulation,* the plate current, varied proportionally thereto, is made to *reproduce* the modulation of the signal in amplified form, by the relay action of the tube. The three-electrode detector thus *reproduces* the intelligence in the local battery current by modulation-

* In code transmission, the amplitude is raised to maximum for the duration of a dot or dash and dropped to a minimum value or zero at the end of a dot or dash. In the case of speech or modulated continuous wave transmission, the amplitude is intermediately varied at an audio frequency.

amplifying relay action; it controls by relay action a new current which operates the indicator; it does not rectify the weak signal current to operate an indicator in the received signal circuit.

The "grid condenser-grid leak" detector has essentially the same mode of operation. Normally, an incoming wireless signal is carried by a continuous carrier wave of high frequency. When the wave arrives, the first few impulses charge the condenser with negative charges until a basic voltage is reached which is a balance between the average of the incoming pulses and the leakage through the high resistance which shunts the condenser. Thereafter, the basic voltage charge on the condenser and grid follows the average of the audio-modulation borne by the carrier wave. The grid, having a basic potential thus varied in accordance with the audio-modulation of the incoming signal, by relay action controls the electron stream as in the first type, except that its basic control is in this case the audio frequency variation of its potential produced by the grid leak and condenser. Hence, the average voltage on the grid, by relay action, varies the averaged value of the plate current to make it *reproduce* in its variations the modulation of the signal in amplified form (I R, 626–632).

Even if there is theoretically some preliminary flow of signal energy to the grid condenser while it is charging, resulting in a slight rectification of the current before the condenser is charged to

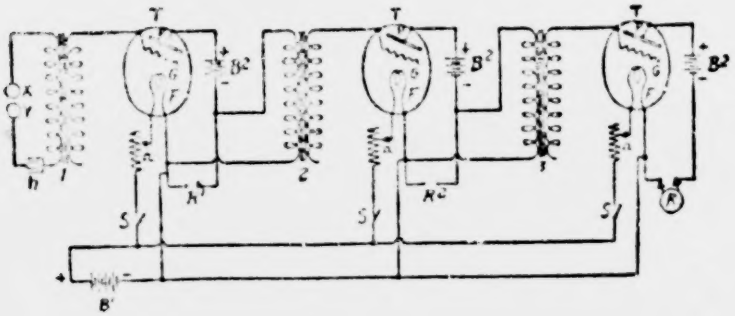
its average potential, such flow is only temporary and in any event is not used to operate any indicator as in the Fleming device. The only indication of the signal in defendant's detectors is that of the averaged variation of the direct current in the plate circuit. The defendant's indicating device in the plate-to-filament circuit is operated solely by the large local energy, which usually is thousands of times greater than the incoming signal energy. Indeed, even if the signal energy (high frequency alternating current) could get over into the plate circuit, it could not operate the indicating device or have any effect upon it.

The triodes used in defendant's detectors served not as rectifiers, but as relay devices repeating, in the locally generated current in the plate circuit, amplified replicas of voltage changes produced on the grid by the incoming alternating current, suitably modified. In the first type above, the modification was obtained by use of a small local *C* battery in the grid circuit, giving it an initial negative charge. In the second type, it was obtained by employing the grid condenser and leak to cause the averaged grid potential to follow the audio modulation of the incoming signal. The court below therefore properly found that defendant's detectors differ from Fleming's in arrangement, operation and result (Findings LXXV, LXXVII, LXXIX, I R. 69–73).

(c) The Three-Electrode Tube as Amplifier

The three-electrode tubes used by defendant as amplifiers were audio frequency amplifiers. One example was the De Forest "Audion Amplifier" used by the Navy Department, and illustrated as follows (Ex. 85, I R. 72):

DE FOREST AUDION AMPLIFIER
USED BY NAVY



Another example of defendant's low frequency amplifiers is that used in the "T. P. S." set. The instrument shown above is a unit consisting of three *iron core* transformers to each of which is connected the input of an *amplifier* tube, all three tubes and their circuits being alike. The instrument was

> * * * of the three-stage type; each stage consisted of an iron-core transformer, 1, 2, 3, three-element audion T, battery B,

---

[2] Telegraphy through the earth's surface, as shown in the early Dolbear patent No. 350,299 (Ex. N 4, not reproduced) and by Preece (Ex. 123, not reproduced, and Ex. S 6, V R. 4163).

resistancer switch S, telephone R, and a filament lighting battery B′, which was common to all three stations. These elements were mounted in a wooden cabinet and the variable portions of the apparatus were operable on the outside. The terminals X Y were connected to the telephone binding posts or terminals of a receiver. The battery B′ was a separate piece of apparatus and connected to terminals on the amplifier. The amplifier element T was renewable. The circuit connections used are as shown in the diagram (Ex. D 2, not reproduced, see I R. 686).

In both types of defendant's amplifiers, however, the triode is connected to an audio-frequency circuit and is employed to amplify audio-frequency current, as is obvious from the arrangement and structure of the amplifiers.* This meant that the incoming high frequency signal was either converted to, or reproduced as, an audio-frequency signal before it was fed to defendant's amplifiers. There is no evidence and plaintiff indeed does not contend that defendant ever used any of these tubes as radio frequency amplifiers; consequently, defendant's amplifiers

* Defendant's amplifiers, when used in a radio receiver, were connected to the telephone terminals, i. e., in an audio-frequency circuit (I R. 635, 636), for the telephone must be in an audio-frequency circuit in order that an operator may hear the sign l. *Iron* core transformers are useful only in low frequency circuits, *air* core transformers being used for high frequency circuits.

are not within the language of Fleming's claim 37, which is limited to Hertzian waves of inaudible frequencies, nor within the language of claim 1, which by the disclaimer in 1915 was restricted to high frequency waves (see p. 189 *supra*).

Even if used with high-frequency currents, there would be no similarity between defendant's amplifiers and the Fleming patent, for in the amplifiers there is no rectification as in Fleming; there is only a direct current, the amount of which by relay action is made to vary in accordance with the variation of voltage on the grid, to *reproduce* in the plate current, a replica of the input signal.[*]

The difference between the Fleming two-electrode tube and defendant's three-electrode tubes operating in the amplifier circuit is illustrated in Dr. Miller's sketch shown at p. 148 *supra*. In the Fleming circuit the input energy is rectified, i. e., one-half of each wave cut off (see lower left-hand figure, p. 148, *supra*), each half wave starting from zero, rising to maximum and falling to zero. In the three-electrode amplifier, on the contrary, the current is not rectified in either the

[*] The natural grid voltage is such that the tube will operate on the straight portion of the characteristic curve, whereby variation of grid voltage equally above and below the normal value will cause equal variation of plate current above and below the normal value. Generally, although not necessarily, a C battery is inserted in the grid circuit in order to hold the operation of the tube on the desired part of the characteristic (IV R. 3116-3118).

input or the output circuit. The change in voltage on the grid controls a wholly different circuit, i. e., the plate circuit, in which the direct current rises and decreases in amplitude in accordance with the voltage changes on the grid (p. 142, et seq. *supra*). As already stated, the input energy to defendant's amplifiers was invariably of audio-frequency. Had it been of high frequency, i. e., above the audible range, the output would be a variation of the amplitude of the plate current at the same high frequency, and this variation would be so rapid that nothing would be heard in the phones.

Thus, the defendant's amplifiers are not detectors and do not rectify. Their action is purely that of a relay, the grid voltage controlling the large local energy of the local *B* battery, to produce an *amplified* reproduction of the signal. This most important function and result of the triode amplifier is not attained and not possible in the Fleming device, as plaintiff in fact concedes in its brief (Pl. Brief 56–58). Since the devices function differently, infringement is not established even though there may be nominal or verbal similarity between plaintiff's patent and defendant's structure. *Westinghouse* v. *Boyden*, 170 U. S. 537.

The findings of the court below that the Fleming patent contains no disclosure of a device capable of amplifying (Finding LXXIV, I R. 68, 69) and that the three-electrode amplifier func-

tions in a radically different manner from that contemplated by Fleming (Finding LXXVI, I R. 72, 73), are thus clearly supported by the evidence.

(d) The Three-Electrode Tube as Oscillator

Defendant's three-electrode tubes, when used as "oscillators" in wireless transmitters, are typified by the General Electric No. 2, which is illustrated as follows (Ex. 116, IV R. 2792):

General Electric No. 2

The device, whose function is to send out a continuous wave, operates as follows: The grid and plate circuits are coupled by the coils d' d^2 so that any disturbance in either circuit is inductively communicated to the other. The path of the direct current in the plate circuit is from battery B' to the filament F, thence to plate P and back to battery. The alternating component

of this current is shunted from plate P through condenser c^2, coil d^2, wire 3, filament F to plate P'.[52]

The alternating component of the large plate current, caused by the rise of current in the coil d', is communicated to the grid circuit by means of the shunt circuit, causing the grid circuit still further to increase the alternations in the plate circuit (by the amplifying action of the tube), until a state of equilibrium is attained in the plate and grid circuits, after which the alternations continue at a constant amplitude. These alternations are impressed on the antenna by the coupling transformer d' d^2 and are sent out as high frequency waves.

In this arrangement, the three-electrode tube operates as an oscillator producing a wave to be transmitted. The Fleming device, on the other hand, is a receiver only; it is in no sense a transmitter, could not function as a transmitter, and could not be used to send out a continuous wave.[53]

[52] The condenser c^2 prevents the battery B^2 from short circuiting through coil d^2; and a choke coil (not shown) in the battery lead directly adjacent to the battery B^2 prevents the alternating component from flowing by way of the battery.

[53] Plaintiff's suggestion in the court below that the defendant's oscillator is a reversal of the Fleming or Edison valve is wholly unfounded, for there is no known way of reversing the Fleming device. It has only one circuit, and whether the current applied thereto is direct current or alternating current, the result is the same: current flows through the

Its sole function is to permit the measurement or indication of rectified high frequency current, and Fleming's patent so recites (V R. 2600, lines 25–30). It is overwhelmingly established that the two-electrode tube, with or without a battery, cannot cause oscillations, and plaintiff now concedes this (Pl. Brief 56, 58). Indeed, plaintiff asserts (*Id.* 57) that it—

> has never claimed that the Fleming patent describes amplification, oscillation or * * * use of gas or external field (to produce these effects), or that Fleming knew these things.

The plaintiff thus concurs in the finding of the court below in these respects (Findings LXXIV, LXXVI; I R. 68–79, 72–73). It urges, however, that because defendant's detectors, amplifiers, and oscillators use unidirectional conductivity, they in-

---

device in one direction only. If the applied current is direct current, the flow will be continuous; if alternating current, the current flow in the circuit will be a series of pulsations of direct current. The same is true even if the circuit be split in two halves, as suggested by Waterman.

Nor is the three-electrode tube reversible in any sense. In fact, one of its important characteristics is that it is unidirectional only, i.e., changes in the grid circuit are reflected in the independent current of the plate circuit, but changes in the plate circuit do not go back through the tube. Even when fed back by a feed back connection, the reproduction through the tube is still unidirectional. This feature was recognized by de Valbreuze, Wehnelt, Fleming, and others as a characteristic of the Edison and similar two-electrode tubes, years before the patent in suit was applied for.

fringe the Fleming patent. But as shown above (p. 110–127 *supra*), and as the court below properly found (Findings LXXI, LXXII; I R. 66–67), this feature was attributable to Edison and to the investigations which were published and became part of the public domain long before the application for the Fleming patent. Charges of infringement may not be based upon an element in a patented device which the prior art had disclosed. *United States* v. *Berdan Fire Arms Co.*, 156 U. S. 552. The court below correctly found, therefore, that the Fleming patent disclosed no device capable of oscillating (Finding LXXIV, I R. 68, 69) and that the three-electrode oscillators differ in arrangement, mode of operation, and result from anything contemplated in the Fleming patent (Finding LXXVIII, I R. 73).

3. *Commercial Success of the Three-Electrode Device*

The rapidity with which the triode replaced the older form of tubes, and its signal contributions to the art of communication, add to the evidence of its substantial dissimilarity to Fleming's diode. As the court below found, the speedy advancement of the art was attributable to the differences between the three-electrode tube and Fleming's tube, and not to matter contemplated in the Fleming patent (Findings LXXIV and LXXVII, I R. 68, 73). DeForest's device was in every sense a

true relay or amplifier, and by locating a telephone or other indicating device in the powerful local plate circuit and controlling it by the weaker input circuit, greater signal strength and fidelity of detection and reproduction resulted.

Few inventions since the telephone have wrought more revolutionary changes and established more new industries than has this new instrumentality. The three-electrode tube shortly after its invention was developed by the telephone companies into "a most successful speech amplifier or telephone relay" (I R. 710), and it is to the inertialess relay-amplification possible with this instrument that we owe our long distance telephone, and wireless broadcast transmitting stations and receivers, talking moving pictures, and public address systems. Dr. Eccles, an English scientist of high standing, wrote in 1919 that

> it is the three-electrode valve, and not the valve with two electrodes, that has been responsible for the overthrowing of the old methods and apparatus. That it has been a veritable revolution can be seen by comparing the common practice in wireless telegraphy of 1914 with that of 1919 (Ex. W, I R. 653).

Dr. Van Der Bijl, one of the highest wireless authorities in this country (Ex. L, IV R. 3304), agreed that

> the insertion of the grid into the valve resulted in a device of tremendous potentiali-

> ties—one that can justly be placed in the same category with such fundamental devices as the steam engine, the dynamo, and the telephone.

and added that

> the insertion of the grid has made the audion a device of immense practical importance and enabled it to perform functions that would otherwise have been impossible.

By way of summary, and to show more clearly the substantial differences between Fleming's and the defendant's tubes, we have prepared a table (Table 3) listing in parallel columns the distinctive criteria of infringement: of arrangement of parts, mode of operation and result, of the Fleming patent and of DeForest's three-electrode tubes. Comparison of these columns emphasizes the correctness of the finding below that defendant's device differed in arrangement, mode of operation and result from that of Fleming (Findings LXIX–LXXVII; I R. 64–73). The ultimate finding of noninfringement (Finding 1; I R. 117) necessarily follows from any one of these differences.[56]

TABLE 3

STRUCTURE

Fleming tube and circuit	Defendant's (DeForest) tube and circuit
(1) Electron-emitting filament heated by battery, or by input current.[1]	(1) Electron emitting filament heated by battery.[1]
(2) Cold plate.[1]	(2) Cold plate.[1]
(3) (absent)	(3) Interposed grid, connected in circuit to filament.
(4) (a) Incoming alternating current connected in a circuit between plate 2 and filament (1), the alternating current to be of high or [illegible] frequency.	(4) (a) (absent)
(b) (absent)	(b) Incoming alternating current connected in grid-to-filament circuit.
(5) (absent)	(5) High voltage local battery connected in the plate-to-filament circuit, with its positive end to plate and its negative end to filament.
(6) (absent)	(6) Means in the grid-to-filament circuit for controlling the initial negative charge on the grid relative to the filament, either a low voltage C battery connected in the grid circuit or a condenser bridged by a high resistance connected in the grid circuit.

[1] These two elements were in the prior art. See Table 2.

STRUCTURE—Continued

Fleming tube and circuit	Defendant's (DeForest) tube and circuit
(7) (a) A galvanometer in the circuit to which the incoming alternating current is applied, which is energized by the one-way flow of the incoming alternating current permitted by the unidirectional conductivity of the tube	(7) (a) (absent).
(b) (absent).	(b) An indicator actuated by the fluctuation of the local battery current in the plate-to-filament circuit

OPERATION

(1) The plate is alternately made positive and negative relative to the filament by the incoming alternating current	(1) The plate remains positive relative to the filament at all times
(2) (absent)	(2) The plate circuit current is derived from the high voltage local battery in the plate-to-filament circuit
(3) The rectified alternating current in the single circuit of the device flows through and actuates the indicator.	(3) In the amplifiers, oscillators, and C battery-biased grid detectors, any minor unidirectional current existing in the grid-to-filament circuit, to which the incoming alternating current is applied, is simply waste

OPERATION—Continued

Fleming tube and circuit	Defendant's (DeForest) tube and circuit
(4) Not so used in any circuit.	(4) In the "grid condenser-grid leak" detector, the unidirectional current in the grid circuit is used to charge the grid condenser to give it a basic negative charge or bias relative to the filament. The basic static charge on the grid tends to become more negative when the amplitude of the received oscillation is greater, and less negative when the amplitude of the received oscillation is less, thus automatically following the audio-frequency variation in amplitude (modulation) of the oscillations, and causing those audio-frequency variations to be reflected in the plate circuit current.
(5) Limited by disclaimer to rectification of high (Hertzian wave) frequencies.	(5) All defendant's *amplifiers* act to *reproduce*, in the plate current variation, a substantial replica of the audio-oscillations introduced into the grid circuit, without rectification.

RESULT

(a) The Fleming device *rectifies* alternating input currents applied to its indicator circuit, and applies them to actuate a galvanometer in the same circuit, reducing their amplitude in the process.	(a) (absent).

RESULT—Continued

Fleming tube and circuit	Defendant's (DeForest) tube and circuit
(b) The Fleming device is not a relay and as disclosed cannot amplify or oscillate and does not *reproduce* anything in a new local current.	(b) The tube is a true *relay*, and an *amplifier*, and is capable of sustaining its own operation as an oscillation generator, without other elements acting within the tube envelope. As a detector, the tube is likewise a true relay and acts by "modulation-amplifying relay action" to *reproduce* in a new current in the plate circuit an amplified replica of the grid-received modulation.

4. *Plaintiff's favorable decision in 1916 against the DeForest three-electrode tube is not entitled to weight in this case*

Plaintiff relies upon *Marconi Wireless Telegraph Co. of America* v. *DeForest Radio Telephone & Telegraph Co.*, 236 Fed. 942 (S. D. N. Y.), affirmed 243 Fed. 551 (C. C. A. 2), which held the Fleming patent here involved to be valid and infringed by DeForest's three-electrode tubes. That decision, however, is entitled to little weight on either of these issues, for both parties had there agreed, for collateral reasons, that the two-electrode and three-electrode vacuum tubes were essentially alike, thus eliminating any controversy on the matter crucial to the decision here.

In the *DeForest* case, the plaintiff herein alleged infringement of the Fleming patent in

suit by DeForest's three-electrode tubes used as detectors by the DeForest Radio Telephone & Telegraph Company. The DeForest Company counterclaimed upon eight patents, six relating to two-electrode tubes, and two relating to the *three*-electrode tube. Marconi then confessed judgment as to infringement of both of DeForest's *three*-electrode patents (236 Fed. 942, 943; 243 Fed. 560, 561), and the case thereupon proceeded upon the Fleming patent here involved and the six remaining DeForest patents, all for *two*-electrode tubes. Both parties were actually using three-electrode tubes, and were suing on their respective two-electrode patents. Each was claiming that its own two-electrode patents were being infringed by the three-electrode devices of the other. Consequently, it was to the interest of both parties to have the court find substantial similarity between the patented two-electrode and the allegedly infringing three-electrode devices, and by the same token to have the court minimize the differences between the two types.[*] And both parties accordingly informed Judge Mayer of the district court that they considered the two-element and three-element tubes to operate on the

[*] The same observation applies to the minimizing, before Judge Mayer, of the difference between the *B* battery of the three-electrode circuit, which supplied the direct output current to the filament-to-plate circuit, and a mere sensitizing battery attached to the plate of the two-electrode tube, contributing no power to the output of the two-electrode tube.

same principle. The court quite naturally construed the prior art in the light of that concession, saying (236 Fed. 942, 953):

> In reading this literature it must be remembered that both sides agree that the DeForest two-element and three-element bulbs operate on the same principle.

The record in that case embodies no indication of the highly significant facts that by 1916 (the date of the decision) the Fleming valves had been discarded almost entirely as detectors in wireless communication apparatus, that ordinary crystals had been substituted in their place, and that the only vacuum tube in wide use was the three-electrode tube (Finding LXVIII, I R. 63). These circumstances render of little weight the district court's holding that the two-element device had brought into the art a "new, valuable, and easily obtainable detector which has gone into important commercial use."

The affirmance of the judgment by the circuit court of appeals is likewise deprived of weight by the parties' agreement and the inadequate record as to the desuetude of the two-electrode detector. The circuit court of appeals said (243 Fed. 561, 565):

> The detectors called by defendant "Marconi's earlier infringement" or the "two-electrode audion" are especially complained of, though since *it is agreed that the "two*

> *and three-electrode audions" operate on the same basic principle,* no reason appears why defendant must not contend that the same things which admittedly infringe the confessed patents also infringe all the counter-claim patents. [Italics supplied.]

In consequence of the fundamentally erroneous assumption on the part of the two Federal courts (premised upon the parties' agreement on the crucial issue: substantial similiarity of operation) and the courts' misconception of the commercial importance of Fleming's device, their opinions were properly accorded little value by the Court of Claims on the question of whether defendant's three-electrode detectors function in substantially the same way as Fleming's two-electrode tubes. And for like reasons, the decision is entitled to no more weight on the issue of validity. Since neither the district court nor the circuit court of appeals appreciated that the art prior to Fleming knew a rectifier would act as a detector, and that an electronic device that would rectify oscillations of low frequency would likewise rectify radio frequency waves, their contrary conclusions (243 Fed. 561, 563) can hardly be cited as authority in a case where these misconceptions do not exist.[88]

After the affirmance of its decision as to validity and infringement, the district court extended

[88] The finding of the Court of Claims with respect to the de Valbreuze patent alone (Finding LXX, pp. 64–66) discloses this misunderstanding in the *DeForest* case.

its decree to amplifiers and oscillators, on the theory that the Fleming valve was inherently capable of oscillating. 261 Fed. 393. This extension is in effect repudiated by plaintiff, for it now admits that "a simple diode cannot amplify, because it merely changes the form of the received currents" (Pl. Brief 56), while it concedes that the triode is both an amplifier and an oscillator (*id.* 57).[57]

CONCLUSION

For the foregoing reasons the judgment of the Court of Claims with respect to all claims except

[57] The devices called "amplifiers" in the *DeForest* opinion extending the decree were totally unlike the amplifiers in this case. The word "amplifier" was used to designate an assemblage of apparatus comprising two or more detectors, as Judge Mayer's opinion shows. Since the Government's amplifiers comprised no detectors, Judge Mayer's "amplifier" decision is in effect a holding that the defendant's amplifiers here do not infringe, for to find infringement he had to find that the DeForest "amplifiers" really were "detectors". Plaintiff's experts admitted in the record of the present case, and plaintiff now concedes (Pl. Brief 58), that amplification or oscillation was obtained in the demonstrations before Judge Mayer in the *DeForest case* "by gas inside the tube or by an electric field outside the tube", i. e., by converting the tube into a "negative resistance" device or by supplying the equivalent of DeForest's third electrode. In *Hewitt* v. *American Tel. and Tel. Co.*, 272 Fed. 194, Judge Mayer reversed his former viewpoint and held that the amplification obtained by gas characteristics (the manner in which the two-electrode valve was "demonstrated" before him in the *DeForest* case) is a wholly different thing from the relay amplification and oscillation attained by grid control, as in a three-electrode device.

claim 16 of the Marconi patent No. 763,772, and with respect to the Fleming patent No. 803,684, should be affirmed.

APPENDIX

The Act of June 25, 1910, c. 423, 36 Stat. 851 (35 U. S. C. § 68) provided:

> That whenever an invention described in and covered by a patent of the United States shall hereafter be used by the United States without license of the owner thereof or lawful right to use the same, such owner may recover reasonable compensation for such use by suit in the Court of Claims: * * * *Provided further,* That in any such suit the United States may avail itself of any and all defenses, general or special, which might be pleaded by a defendant in an action for infringement, as set forth in Title Sixty of the Revised Statutes, or otherwise * * *.

This was amended by the Act of July 1, 1918, c. 114, 40 Stat. 704, to read as follows:

> That whenever an invention described in and covered by a patent of the United States shall hereafter be used or manufactured by or for the United States without license of the owner thereof or lawful right to use or manufacture the same, such owner's remedy shall be by suit against the United States in the Court of Claims for the recovery of his reasonable and entire compensation for such use and manufacture: * * * *Provided further,* That in any such suit the United States may avail itself of any and all defenses, general or special, that might be pleaded by a de-

fendant in an action for infringement, as set forth in Title Sixty of the Revised Statutes, or otherwise * * *.

Section 3 (b) of the Act of February 13, 1925, c. 229, 43 Stat. 936, 939, as amended by the Act of May 22, 1939, c. 140, 53 Stat. 752, 28 U. S. C. § 288 (b), provides:

> In any case in the Court of Claims, including those begun under section 180 of the Judicial Code, it shall be competent for the Supreme Court, upon the petition of either party, whether Government or claimant, to require, by certiorari, that the cause be certified to it for review and determination of all errors assigned, with the same power and authority, and with like effect, as if the cause had been brought there by appeal. In such event, the Court of Claims shall include in the papers certified by it the findings of fact, the conclusions of law, and the judgment or decree, as well as such other parts of the record as are material to the errors assigned, to be settled by the Court.
>
> The Court of Claims shall promulgate rules to govern the preparation of such record in accordance with the provisions of this section.
>
> In such cases the Supreme Court shall have authority to review, in addition to other questions of law, errors assigned to the effect that there is a lack of substantial evidence to sustain a finding of fact; that an ultimate finding or findings are not sustained by the findings of evidentiary or primary facts; or that there is a failure to make any finding of fact on a material issue.

Sections 4917 and 4922 of the Revised Statutes (35 U. S. C. §§ 65, 71) provide:

> SEC. 4917. Whenever, through inadvertence, accident, or mistake, and without any fraudulent or deceptive intention, a patentee has claimed more than that of which he was the original or first inventor or discoverer, his patents shall be valid for all that part which is truly and justly his own, provided the same is a material or substantial part of the thing patented; and any such patentee, his heirs or assigns, whether of the whole or any sectional interest therein, may, on payment of the fee required by law, make disclaimer of such parts of the thing patented as he shall not choose to claim or to hold by virtue of the patent or assignment, stating therein the extent of his interest in such patent. Such disclaimer shall be in writing, attested by one or more witnesses, and recorded in the Patent Office; and it shall thereafter be considered as part of the original specification to the extent of the interest possessed by the claimant and by those claiming under him after the record thereof. But no such disclaimer shall affect any action pending at the time of its being filed, except so far as may relate to the question of unreasonable neglect or delay in filing it.
>
> SEC. 4922. Whenever, through inadvertence, accident, or mistake, and without any willful default, or intent to defraud or mislead the public, a patentee has, in his specification, claimed to be the original and first inventor or discoverer of any material or substantial part of the thing patented, of which he was not the original and first inventor or discoverer, every such patentee,

his executors, administrators, and assigns, whether of the whole or any sectional interest in the patent, may maintain a suit at law or in equity, for the infringement of any part thereof, which was bona fide his own, if it is a material and substantial part of the thing patented, and definitely distinguishable from the parts claimed without right, notwithstanding the specifications may embrace more than that of which the patentee was the first inventor or discoverer. But in every such case in which a judgment or decree shall be rendered for the plaintiff, no costs shall be recovered unless the proper disclaimer has been entered at the Patent Office before the commencement of the suit. But no patentee shall be entitled to the benefits of this section if he has unreasonably neglected or delayed to enter a disclaimer.

OCTOBER TERM, 1942

No. 373

THE UNITED STATES, CROSS-PETITIONER

v.

MARCONI WIRELESS TELEGRAPH COMPANY OF AMERICA

CROSS-PETITION FOR A WRIT OF CERTIORARI TO THE COURT OF CLAIMS

On September 2, 1942, Marconi Wireless Telegraph Company of America, the plaintiff in the Court of Claims, filed a petition for writ of certiorari in *Marconi Wireless Telegraph Company of America* v. *The United States*, No. 369, seeking a review of those portions of the interlocutory and final judgments of the Court of Claims of the United States, rendered November 4, 1935, and April 6, 1942, respectively, which hold invalid certain claims of United States Patent No. 763,772 granted to Guglielmo Marconi on June 28, 1904, and hold certain claims of United States Patent

No. 803,684, issued to John Ambrose Fleming on November 7, 1905, not infringed by the United States. A brief in opposition to the petition is being prepared and will be filed on behalf of the United States.

The Solicitor General on behalf of the United States prays that in the event the Court grants the petition in No. 369, but only in that event, a cross-writ of certiorari be directed to the Court of Claims to review that portion of the judgment rendered April 6, 1942, which awards damages against the United States for infringement of Claim 16 of the Marconi patent. The certified transcript of record filed in No. 369 includes those portions of the record upon which this cross-petition is based.

OPINIONS BELOW

The opinion of the Court of Claims on the issues of validity and infringement (R. 7–116) is reported at 81 C. Cls. 671; its opinion in the accounting proceeding (R. 117–182) is not yet reported.

JURISDICTION

The interlocutory judgment of the Court of Claims upholding the validity of Claim 16 of the Marconi patent, in pursuance of which an accounting was held, was rendered November 4, 1935. The final judgment after accounting proceedings was rendered April 6, 1942. Time in which to file a petition and cross-petition for writs of certiorari was extended by the Chief Justice for a period

of 60 days from July 6, 1942 (R. 2523). The jurisdiction of this Court is invoked under section 3 (b) of the Act of February 13, 1925, as amended.

QUESTIONS PRESENTED

(1) Whether the Court of Claims erred in holding Claim 16 of the Marconi tuning patent (No. 763,772) valid and infringed. A subsidiary question is whether in the circumstances the court erred in refusing to consider evidence material to these issues introduced in the accounting proceedings.

(2) Whether in the absence of any finding or evidence which would have supported a finding that the patented receiver disclosed or attained the principal advantage attained by the receiver used by the United States, the Court of Claims could properly use the value of that advantage as a measure of compensation against the Government.

STATEMENT

The patent involved in this case and, with the Fleming patent (No. 803,684), involved also in No. 369, is United States Patent No. 763,772, granted to Guglielmo Marconi on June 28, 1904, and known as the Marconi four-circuit tuning patent (Pl. Ex. 21, Petition, Appendix C). This patent, now expired, related to wireless transmitting and receiving apparatus. More specifically, it relates to means for providing a stronger transmitted

signal and a more selective reception than had been attained prior to Marconi's disclosure. The alleged invention comprised a variably tuned antenna circuit inductively coupled through an oscillation transformer to a tuned closed oscillating circuit in both the transmitter and receiver. The patent specified that each of the four circuits should be tuned to the same frequency in order to secure the desired objects of strong signals and of selective reception. (See Finding XXXVIII, R. 31.)[1]

The patent included twenty claims, of which fifteen were involved in the suit below. Two of these claimed tuning the two transmitter and the two receiver circuits to the same wave length or frequency. Six were directed to the transmitter alone, and claimed tuning the transmitter circuits to the same frequency. The remaining seven claims in suit, including Claim 16, were directed to the receiver alone, and claimed tuning the two circuits at the receiver (*i. e.*, the antenna or open circuit, and the detecting circuit) to the same frequency.

The Court of Claims held that all of these claims except Claim 16 were anticipated by the prior work of John Stone Stone (Findings LVII and LVIII,

[1] References to Findings of Fact unless otherwise indicated are to those appearing in the Court of Claims decision of November 4, 1935.

R. 56–57). Claim 16,[2] while claiming means for tuning the two receiver circuits to the same frequency as did the six other receiver claims in suit, was held to be distinguished from them and from the prior art because of the additional element of an adjustable condenser connected with the open circuit and in shunt with the primary winding (j′) of the transformer (j′–j²) of the receiver. The court below found that the purpose of this condenser, as indicated in "the tables on page 4 of the specification * * *, is to enable the electrical periodicity or tuning of the open circuit of the receiver to be altered." (Finding LX, R. 57.) It concluded that Claim 16 was valid and had been infringed by the United States (R. 75).

During both the initial hearing and the subsequent hearing on accounting the Government contended and introduced evidence to show that Claim 16, to the extent valid at all, was not infringed. The evidence showed and the court found that the laws regarding the relationship of capacity and

[2] "16. At a receiving station employed in a wireless-telegraph system, the combination of an oscillation transformer, an open circuit connected with one coil of said transformer, said circuit including an oscillation-receiver conductor at one end and capacity at the other end, an adjustable condenser in a shunt connected with the open circuit and around said transformer coil, a wave-responsive device electrically connected with the other coil of the oscillation transformer, and means for adjusting the two transformer circuits in electrical resonance with each other, substantially as described."

inductance to achieve the tuning of an alternating current circuit were known prior to the Lodge patent (No. 609,154) (also in suit in the court below), which antedated the Marconi patent, and that Lodge taught the art to apply these laws to the so-called "open" antenna circuit (Findings XXXVI, LXI, R. 29–30, 57). The evidence also established and the court found that persons skilled in the art knew prior to Marconi's patent how to adjust the condensers shown in Stone's earlier patent to achieve the desired tuning, even though Stone's drawing did not show that his condensers were adjustable (Finding LIII, R. 47–51). In addition, the Fessenden patent as filed [3] prior to the earliest date proven for Marconi, showed an adjustable condenser in shunt with all the inductance coils in the antenna circuit of a wireless receiver; and the Pupin patent,[4] also prior to Marconi, not only showed a similar arrangement, but fully explained the laws governing its operation, which were known at the time of Fessenden's application in 1899. (Findings XXXVI, LIII, R. 29–30, 47.)

As appears from the face of the patents, the only novel difference between the condenser arrangement shown by Marconi and that disclosed by Fessenden and Pupin is that in every instance in which the condenser (h) is present in the

[3] Patent No. 706,735, Pl. Ex. 171, pages, 90, 93; Def. Exs. LL and CCCC, Fig. 1.

[4] Patent No. 640,516, Def. Exs. U–2 and KK (Fig. 2).

tables on page 4 of the Marconi specification, referred to by the court in the quotation *supra*, p. 5, a variable inductance tuning coil (g′) not bridged by the condenser is employed,[5] whereas in the Fessenden and Pupin constructions there were no inductance coils not bridged by the condenser. The evidence shows that the same difference exists between Marconi's claimed invention and the receivers used by the Government, where the variable condenser alleged to infringe is employed in the open circuit. The court below in its findings of fact reproduced the drawings of the two types of circuit employed by the Government, and these drawings show that in each instance the condenser (h) in its solid-line position[6] bridges all the inductance coils (that is, both g and j) in the circuit between the aerial and ground (Finding 23, April 6, 1942, R. 139).

The evidence shows that this difference in arrangement produces a difference in mode of operation of the circuits yielding diametrically opposed results: In the Marconi arrangement the presence

[5] The text of the Marconi patent (p. 1, lines 56–59) states: "The system also requires as *essential elements* thereof the inclusion in the lines (at both stations) from the aerial conductor to the earth of *variable inductances* * * *." (Italics supplied.) The only variable inductance disclosed in the antenna circuit of the receiver is the tuning coil (g′), which is *not* bridged by the condenser (h) (Finding XXXVIII, R. 31–32).

[6] The dotted-line position is an alternative arrangement of the condenser not alleged to infringe (see Finding 23, April 6, 1942, R. 139).

of the condenser in series between tuning coil g' and the earth, makes the condenser act in *series* with the antenna-to-earth capacity and causes the primary tuned circuit to respond to *decreased* wave lengths;[7] in the Government's structure the presence of the condenser in parallel with *all* the inductance coils in the circuit, places it in *parallel* with the antenna-to-earth capacity and causes the primary tuned circuit to respond to *increased* wave lengths.[8] The court below, in the accounting proceeding, found in effect that the shunt-connected condenser in cross-petitioner's receiver enabled the receiver to be tuned to longer wave lengths than would be the case with the normal connection (Findings Nos. 28, 29 and 45, April 6, 1942, R. 143, 156). It made no finding that the Marconi circuit was designed for this purpose or achieved this result and the only testimony was to

[7] *Tuska*, R. 2509, XQQ. 266, 268; *Wheeler*, R. 2434 (Q. 55), 2438, 2451, 146 Q.; Def. Ex. BBB; *Waterman*, R. 357-358; *Loftin*, R. 977.

[8] *Pickard*, R. 2328-2335; *Tuska*, R. 2498, Q. 107.

[9] The experts who testified below were agreed that the Marconi shunt-condenser-connection was merely a "by-path" around only the coupling coil j' (not bridging the antenna tuning coil g'; see note 7, *supra*) and had no important modifying effect on the general mode of operation. The only significant result of the condenser as used in the Marconi patent was to effect a loose coupling arrangement, which was not used in the Government's structure. The decrease in wave length caused by the condenser as used was slight and incidental. (*Tuska*, R. 2509, XQQ. 266, 268; *Loftin*, *Wheeler*, *Dow*, R. 977; 2434 (Q. 55), 2477 (124 Q.), 2465 (255 XQ.); 2364, 2367; *Waterman*, R. 357, 358).

the contrary.[2] It simply found in its decision of November 5, 1935, that the Government's receivers had "apparatus coming within the terminology of Claim 16" (Finding LXIII, R. 60), and, in its decision after the accounting proceeding, that "The adjustable condenser in such a circuit had the function and effect similar to that possessed by the adjustable condenser of the Marconi patent * * *." (Finding 24, April 6, 1942, R. 139.)

In the accounting proceeding the Marconi Company proved, and the court below found (Findings 29 and 45, April 6, 1942, R. 143, 154), that in the Government's receiver the shunt-connected condenser enabled the receiver to be tuned to longer wave lengths than would be the case with the normal connection, and enabled the periodicity of the open circuit to be broadly changed. The court then found that the same advantages could have been attained by the prior-art method of using an additional inductance coil in the antenna circuit, and the cost of such additional coils would have been $66,130.67, of which the court allowed the plaintiff 65% ($42,984.93) with interest. The court declined to consider evidence adduced by the Government which explained the functions of the condenser in the Marconi arrangement and showed that the advantage of cross-petitioner's device was not attained by the device covered by claim 16 of the Marconi patent. (Opinion, April 6, 1942, end of page 61, R. 176–177.

SPECIFICATION OF ERRORS TO BE URGED

The Court of Claims erred:

(1) In finding as an ultimate fact that claim 16 of the Marconi patent was valid and was infringed, without first determining its scope in view of the prior art.

(2) In failing to make a finding of fact as to the particular advantage achieved by the shunt condenser in the open antenna circuit of the Marconi patent, and in making a finding of infringement in the absence of such finding.

(3) In failing to find as a fact that the disclosure of the Marconi patent upon which claim 16 is based did not possess the principal advantage of cross-petitioner's structure but possessed a different advantage not used by cross-petitioner.

(4) In basing compensation upon the principal advantage present in cross-petitioner's structures, when such advantage was not disclosed or attained in the patent in suit.

(5) In not revising its findings of fact to conform to the entire evidence in the case where evidence necessarily admitted in the accounting proceedings, to establish a basis for compensation, disclosed incompleteness and error in the findings of fact theretofore made in relation to the infringement of claim 16 of the Marconi patent (No. 763,772).

REASONS FOR GRANTING THE WRIT

1. Although the Government is of opinion that neither the questions presented by the petition in No. 369 nor those presented by this cross-petition are of sufficient importance to call for a review by this Court, it submits that if the petition in No. 369 is granted, similar action should be taken in this case. The questions raised herein are at least of equal interest and it would seem desirable for the Court to review all related matters in controversy between the parties if it reviews any. A review in No. 369, unless limited to the Fleming patent, would involve a consideration of all the Marconi tuning claims in suit, including Claim 16 so far as it covers four-circuit tuning.

2. On November 10, 1900, the earliest date established for the Marconi patent (Finding XLI, R. 37), the use of the feature which was held to establish the validity of Claim 16, namely, the use of a condenser in shunt with the transformer primary for the purpose of varying the periodicity of the open circuit, was old in the art. The prior art is exemplified by the Fessenden patent (No. 706,735) granted August 12, 1902, on an application filed December 13, 1899 (Finding XLII, R. 37), and by the Pupin patent (No. 640,516) Def't's. Exh. KK, Fig. 2.) Both show the use of a Def't's. Exh. KK, Fig. 2.). Both show the use of a condenser in shunt with the primary of the transformer coil and both adjust the values of these condensers to vary the periodicity of the circuit.

Claim 16, therefore, is anticipated by these patents, unless it be limited to the feature of a coil not bridged by the condenser in shunt. Cf. *Knapp* v. *Morss*, 150 U. S. 221; *American Fruit Growers, Inc.*, v. *Brogdex Co.*, 283 U. S. 1. But so limited, it was not infringed by the structure used by the Government.

The settled rule is that, to infringe, a structure must be substantially the same as the patented structure in arrangement, mode of operation, and result.[10] The evidence hereinbefore summarized (pp. 5–9) shows that the combination of elements in, mode of operation of, and result attained by the Government's structure are different from those of the Marconi disclosure when Claim 16 is limited in the manner necessary both on principle and to establish its novelty over the prior art; that the circuits of the Fessenden and Pupin patents, which automatically increase the wave length, are substantially the same as the Government's circuits and fully justify the Government's manner of using the condenser to attain an increased wave length;[11] and that the circuit claimed by Marconi does not attain the advantage of increased wave length on the basis of which the Court of Claims computed its award against the United States on the accounting.

[10] *Westinghouse* v. *Boyden Power Brake Co.*, 170 U. S. 537; *Holland Fur. Co.* v. *Perkins Glue Co.*, 277 U. S. 245, 257; *Sanitary Refrigerator Co.* v. *Winters*, 280 U. S. 30, 42; *Craftint Mfg. Co.* v. *Baker*, 94 F. (2d) 369, 373 (C. C. A. 9).

[11] *Knapp* v. *Morss*, *supra*.

3. In basing the amount of the judgment upon the advantage of increased wave length attained by the Government's receiver, without finding that such advantage was disclosed or attained by the patented structure, the Court of Claims reached a result which conflicts in principle with decisions of this Court (*Westinghouse Co.* v. *Wagner Mfg. Co.*, 225 U. S. 604; *Dowagiac Mfg. Co.* v. *Minnesota Plow Co.*, 235 U. S. 641; *Sheldon* v. *Metro-Goldwyn Pictures Corp.*, 309 U. S. 390, 402) and of circuit courts of appeals.[12]

CONCLUSION

For the reasons stated, it is prayed that if the petition for a writ of certiorari in No. 369 is granted to review the decision of the Court of Claims with respect to the Marconi patent (No. 763,772), this petition for a review of the same decision of the Court of Claims with respect to Claim 16 of that patent be granted also.

No. 373

THE UNITED STATES, PETITIONER

v.

MARCONI WIRELESS TELEGRAPH COMPANY OF AMERICA

ON WRIT OF CERTIORARI TO THE COURT OF CLAIMS

BRIEF FOR THE UNITED STATES

OPINIONS BELOW

The opinion of the Court of Claims on the issues of validity and infringement of the patent in suit (I R. 7–116)[1] is reported at 81 C. Cls. 671; its opinion in the accounting proceedings (I R. 117–182) is not yet officially reported.

JURISDICTION

The interlocutory judgment of the Court of Claims concerning validity and infringement pur-

[1] The record citations refer to the volume and page.

suant to which an accounting was held, was rendered November 4, 1935 (I R. 75); the final judgment, after the accounting proceedings, was rendered April 6, 1942 (I R. 182). The petition for a writ of certiorari was filed on September 3, 1942, (III R. 2524), pursuant to an extension of time granted by the Chief Justice (III R. 2523), and was granted on December 14, 1942. The jurisdiction of this Court is invoked under Section 3 (b) of the Act of February 13, 1925, as amended.

QUESTIONS PRESENTED

(1) Whether claim 16 of Marconi patent No. 763,772 was infringed by the United States.

(2) Whether claim 16 of the Marconi patent, if infringed, was valid, or whether it was void for anticipation in the prior art.

(3) A question subsidiary to these two questions is whether the Court of Claims erred in refusing to consider evidence, introduced in the accounting proceedings, material to the issues of validity and infringement.

(4) Whether, even if the claim was valid and was infringed by the United States, the court below properly adopted as a measure of compensation the value of the principal advantage attained by the arrangement used by the Government, in the absence of any finding or any evidence to support a finding that such advantage

was disclosed or attained by Marconi's arrangement.

STATUTE INVOLVED

The Appendix, *infra*, pp. 51–52, contains the pertinent provisions of the Act of June 25, 1910, c. 423, 36 Stat. 851, as amended by the Act of July 1, 1918, c. 114, 40 Stat. 704 (35 U. S. C. § 68), and the pertinent provisions of Section 3 (b) of the Act of February 13, 1925, c. 229, 43 Stat. 936, 939, as amended by the Act of May 22, 1939, c. 140, 53 Stat. 752 (28 U. S. C. § 288b).

STATEMENT

On July 29, 1916, respondent Marconi Wireless Telegraph Company of America (herein called plaintiff) brought this suit in the Court of Claims under the Act of June 25, 1910, to recover compensation for the allegedly unauthorized use by the United States (herein sometimes called defendant) of inventions alleged to have been covered by four patents, two issued to Guglielmo Marconi, one to Sir Oliver Lodge, and one to Sir John Ambrose Fleming.

The court below held that one Marconi patent, reissue No. 11,913 was not infringed, and that the Lodge patent No. 609,154 was valid and infringed.[2] As to these, no review has been sought by either party.

---

[2] The final judgment rendered after the accounting proceedings awarded plaintiff $34,827.70 plus interest for infringement of the Lodge patent. This award is not here involved.

The court below further held that the Fleming patent No. 803,684 had not been infringed and that all the claims in suit (except claim 16) of the other Marconi patent, No. 763,772, were invalid (I R. 75,117). This ruling concerning the Fleming patent and the invalidity of the Marconi patent is now before this Court in *Marconi Wireless Telegraph Company of America* v. *The United States*, No. 369, this Term.

In respect of claim 16 of the Marconi patent, No. 763,772, the court below rendered an interlocutory judgment on November 4, 1935, holding it valid and infringed, and after accounting proceedings, rendered its final judgment (I R. 182), on April 6, 1942, awarding compensation to plaintiff in the amount of $42,984.93 plus interest for such infringement. The decision concerning claim 16 of the Marconi patent is the subject of this proceeding.

Marconi patent No. 763,772 was granted to Guglielmo Marconi on June 28, 1904, and related to wireless transmitting and receiving apparatus. It disclosed an arrangement claimed to provide a stronger transmitted signal and a more selective reception than had been attained prior to Marconi's disclosure (Finding XLI; I R. 37).[3] Claim

---

[3] Findings identified by roman numerals were made by the Court of Claims in connection with its interlocutory judgment of November 4, 1935; findings identified by arabic numerals were made by the Court of Claims after accounting proceedings, and in connection with its final judgment of April 6, 1942.

16 of this patent relates to an alleged improvement in receiving apparatus only (Finding XL; I R. 32; cf. I R. 174, 180).

The earlier receiver claimed to have been improved by Marconi consisted of two circuits: the antenna-circuit and the detector-circuit. The antenna-circuit, which received the transmitted oscillations (signals), had an antenna at one end and a connection to earth at the other; the detector-circuit was coupled to the antenna-circuit through a transformer, and included devices for detecting and translating the signals transmitted (Fig. 13 of Lodge patent, Ex. 20, I R. 26; Finding XXVII; I R. 24). Marconi's alleged invention required, in the receiver, a variably tuned antenna-circuit inductively coupled through an oscillation transformer to a tuned closed oscillating-circuit. The invention also required two similar circuits (antenna circuit and closed circuit) in the transmitter, and the patent specified that each of the four circuits in the transmitter and receiver should be tuned to the same frequency in order to secure the desired objects of strong signals and of selective reception. (See Finding XXXVIII; I R. 31.)

The patent included twenty claims, of which fifteen were involved in the suit below.[4] Of these, seven claims, including claim 16,[5] were directed to the receiver alone; they claimed tuning the two circuits at the receiver (i. e., the antenna or open

---

[5] Claims 2, 13, 14, 16, 17, 18, and 19.

circuit, and the detecting-circuit) to the same frequency (Finding XL; I R. 32).

The Court of Claims held that six of these seven claims were anticipated by the prior work of John Stone Stone (Findings LVII and LVIII; I R. 56–57), but held claim 16 valid and infringed (I R. 75).

SUMMARY OF ARGUMENT

I

The finding of the court below that the Government's receivers infringed claim 16 of the Marconi patent is unsupported by substantial evidence. The distinctive feature of the claim which the court below held saved it from invalidation by the prior art was not shown nor found to be present in the Government's receivers; on the contrary, the record requires the conclusion that the condenser arrangement used by the Government—the device alleged to infringe—differed substantially in association, operation, and result from the arrangement disclosed in claim 16. Moreover, the court made no findings of fact as to these criteria of infringement to sustain its ultimate finding of infringement.

II

If, however, claim 16 is to be so broadly construed as to lead to the conclusion that it was infringed by the Government's condenser arrangement, the claim is invalid because the Government's arrangement was specifically disclosed in the art prior to

Marconi, namely, in the earlier patents of Pupin and Fessenden. The record requires the finding and conclusion that the structure, mode of operation, and result of the Government's arrangement are the same as those disclosed by Pupin and Fessenden; and consequently that claim 16, if it also relates to that arrangement, was void for anticipation in the prior art.

III

The error in the conclusions of the court below that claim 16 of the Marconi patent was valid and infringed was revealed in the record on the first hearing prior to the interlocutory judgment of November 4, 1935; it was further apparent from the absence of evidentiary findings as to substantial identity of arrangement, operation, and result necessary to sustain the conclusion of infringement. The record on the accounting proceeding which followed the interlocutory judgment served to emphasize that claim 16 was either invalid or not infringed. The evidence, necessarily introduced in the accounting proceedings to show the proper apportionment of the value of the advantages of the Government's device between the contributions of Marconi and those of others, demonstrated that Marconi's device and the Government's structure had an entirely different arrangement, operation, and result; and further, that the advantages of the Government's de-

vice were derived not from the Marconi patent but from the prior art disclosures of Pupin and Fessenden. The court below erred in refusing to consider the evidence, introduced in the accounting proceedings, as to these matters.

IV

Even assuming the patent was valid and infringed, the court below erroneously measured the damages. The court correctly found that the Government's arrangement produced the advantages of increased wavelength and sensitivity in tuning and saving in space and weight. The court made no findings, however, and there was no evidence which would have sustained any findings, that such advantages had been contributed by the patented device of Marconi. It was therefore error for the court to adopt these advantages of the Government's receivers as the measure of compensation awarded to the plaintiff.

ARGUMENT

Marconi's claim 16 reads as follows (Ex. 21, IV R. 2596):

> 16. At a receiving-station employed in a wireless-telegraph system, the combination of an oscillation-transformer, an open circuit connected with one coil of said transformer, said circuit including an oscillation-receiving conductor at one end and capacity at the other end, *an adjustable condenser in a shunt connected with the*

open circuit and around said transformer-coil, a wave-responsive device electrically connected with the other coil of the oscillation-transformer, and means for adjusting the two transformer-circuits in electrical resonance with each other, substantially as described. [Italics added.]

The subject matter of this claim is shown as follows in Figure 2 of the Marconi patent, *h* being the "adjustable condenser", *f'*, *A*, *g'*—*E* being the "open circuit" (or aerienna-circuit) and *j'* being the "transformer coil" (Ex. 21, IV R. 2590:

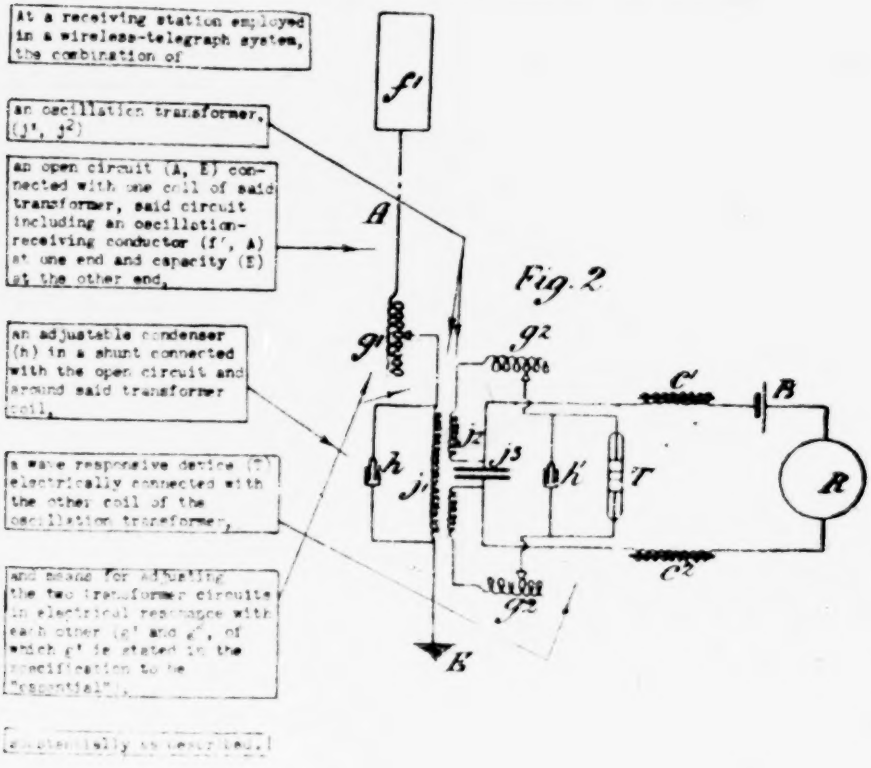

Fig. 2

Like the six other receiver claims which the court below held invalid for anticipation, claim 16 claimed means for tuning the two circuits at the receiver to the same frequency. Claim 16, however, was held to be distinguished from these other claims (and hence from the prior art) by its inclusion of the adjustable condenser *h* connected with the open circuit and in shunt with (i. e., forming a bypath around) the transformer coil *j'*. (See Marconi Figure 2, *supra*, p. 9; Finding LX; I R. 57; cf. I R. 174, 180.)

Since this is the distinctive feature of the claim which saves it from invalidation by the prior art, the question of infringement must turn upon whether or not the Government, in the allegedly infringing receivers, used its condenser in substantially the same association to operate in substantially the same way, and to produce substantially the same result, as the condenser in the arrangement disclosed by Marconi.

If any one of these three requisite elements of similarity is not found in the defendant's device, there can be no infringement.* The court made no specific findings on these three criteria of infringement; moreover, as we shall show in Point I, the evidence requires the conclusion that no one of these criteria was present in the Govern-

* *Westinghouse* v. *Boyden Power Brake Co.*, 170 U. S. 537, 569; *Ciniotti Unhairing Co.* v. *American Fur Refining Co.*, 198 U. S. 399, 414; *Holland Furniture Co.* v. *Perkins Glue Co.*, 277 U. S. 245, 257; *Sanitary Refrigerator Co.* v. *Winters*, 280 U. S. 30, 42; *Craftint Mfg. Co.* v. *Baker*, 94 F. (2d) 369, 373 (C. C. A. 9).

ment's use of its condenser, and hence that no infringement of claim 16 was shown. Consequently, the conclusion of the court below is clearly erroneous because unsupported by substantial evidence and because without subordinate findings of fact to sustain it (Act of May 22, 1939; see Appendix, p. 51, *infra*). Indeed, as we shall show in Point II, if claim 16 is to be so broadly construed as to lead to the conclusion that there was infringement, the claim must necessarily be invalid, for the condenser arrangement used by the Government was specifically disclosed in the art prior to Marconi. This permits, in our view, only two alternatives: that claim 16 was not infringed, or that it is invalid. On either view, the decision below is erroneous. This error was emphasized at the accounting proceedings which followed the interlocutory judgment of validity and infringement; for it was there made clear that the association, operation and result of the Government's condenser arrangement were the same as those disclosed in the art prior to Marconi. The court below should therefore have rectified its prior ruling as to infringement, as requested by the Government prior to entry of final judgment (Point III).

But in any event, even assuming that the claim was valid and infringed, the measure of damages invoked by the court below was erroneous. The advantages which were shown to have been derived from the mode of operation of the Government's arrangement were adopted as the measure of compensation awarded to the plaintiff, although

there was no finding, nor any substantial evidence to support a finding, that such operation and advantages had been disclosed or attained by Marconi's arrangement. In Point IV, we shall show that the use of such advantages as the measure of recovery was therefore improper.

POINT I

The Government's receivers did not infringe Marconi's Claim 16

The record establishes that there are critical differences between claim 16 and the receivers used by defendant; these differences relate to the arrangement, the operation, and the result of the devices in controversy. The essential distinctions between claim 16 and the defendant's receivers negate the conclusion that defendant infringed the claim, and that conclusion is unsupported by substantial evidence.

1. Arrangement

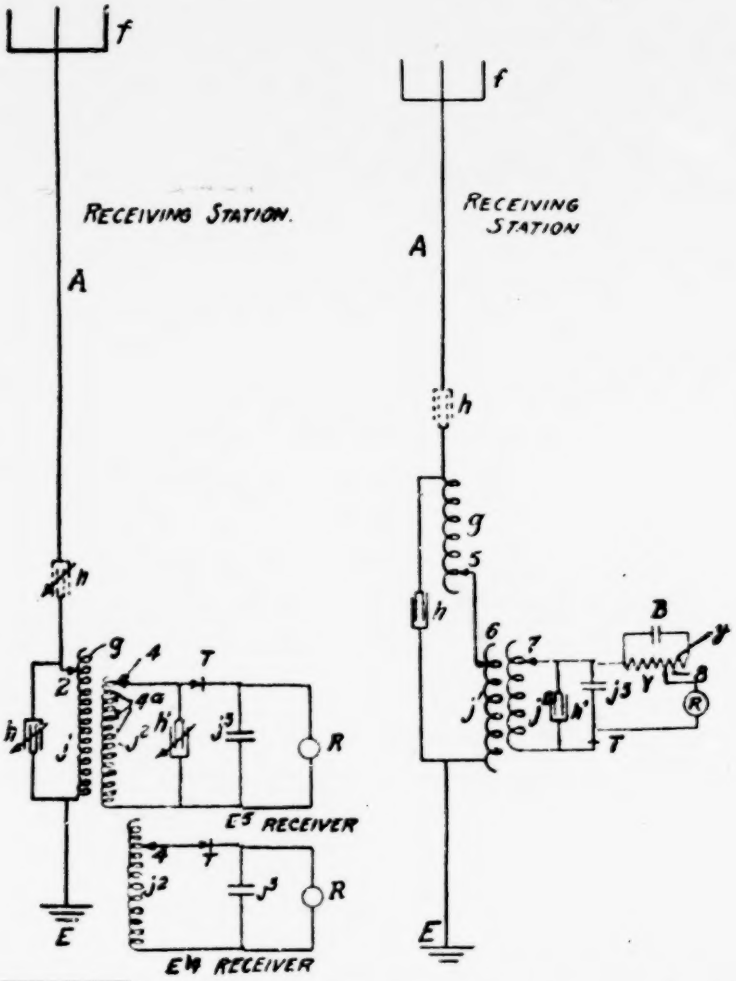
In the Marconi arrangement as disclosed in claim 16, the variable condenser *h* does *not bridge* the variable inductance tuning coil *g'* (see Figure 2, Marconi patent No. 763,772, *supra* p. 9); and this variable tuning coil is stated in the patent to be an *essential* element of Marconi's alleged invention.[1] In contrast, the variable condenser *h* used by the Government in the two types of receivers alleged to infringe claim 16 is invariably

---

[1] The text of the Marconi patent (p. 1, lines 56-59) states:

"The system also requires as essential elements thereof the inclusion in the lines (at both stations) from the aerial conductor to the earth of variable inductances * * *."

connected across *all* the inductance coils (j' and g) in the open circuit (f, A, E), as the following diagram will show:



The only variable inductance disclosed in the antenna circuit of the receiver is the tuning coil q' which is not bridged by the condenser h (Finding XXXVIII, I R. 31–32). In every instance in which the condenser h is present in the tables on page 4 of the Marconi specification, referred to by the court below in Finding LX, the "essential" unbridged coil q' is present.

This fact was indeed expressly found by the court below after the accounting.[8] Plainly, therefore, there is a basic distinction in arrangement between the receiver circuits covered by claim 16 and defendant's circuits.

2. Operation and result

The difference in arrangement of the circuits produces important differences in their operation and results which may be succinctly described as follows: In the Marconi arrangement, the presence of the condenser in *series* between the inductance coil g' and the earth E makes the condenser act in *series* with the antenna-to-earth capacity and tends to cause the primary tuned circuit to respond to *decreased* wave lengths;[9] in the Government's structure, the presence of the condenser in *parallel* with *all* the inductance coils of the circuit places it in *parallel* with the an-

---

[8] Finding 23, I R. 139. This finding relates to the Government's condenser h in its *solid-line* position in the Figures above reproduced, which constituted part of Finding 23. The *dotted-line* position is an alternative arrangement of the condenser, not alleged to infringe claim 16 (Finding 23, I R. 139).

[9] *Dow*, III R. 2364 (Q. 18), 2367; *Tuska*, III R. 2509, X QQ. 266, 268; *Wheeler*, III R. 2434 (Q. 55), 2436 (70 Q), 2451 (Q. 146); Def. Ex. The experts called by plaintiff to testify were Waterman, Tuska, and Pickard; those called by the Government were Loftin, Wheeler, Dow. (See quotations in n. 14, *infra*, p. 17.)

tenna-to-earth capacity and causes the primary tuned circuit to respond to *increased* wave lengths.[10]

Marconi's condenser arrangement has the advantage of shunting or bypassing most of the energy of the antenna circuit around the coupling coil *j'*, thus constituting a means for loosening the coupling between the antenna and secondary circuits. This is different from and possibly an improvement over other loose coupling means theretofore known to the art: the swamping inductances used by Stone (Findings LV and LVII, I R. 52, 56) and the physical separation of coils used by Lodge (Fig. 13, I R. 26; II R. 1018). But the Government does not use the Marconi bypass arrangement for loose coupling; it uses only the earlier alternatives of Stone and Lodge.

To explain the difference in operation and result, we shall advert first to certain accepted laws of radiotelegraphy.

(a) *General Principles*

An electrical circuit can be tuned to a given wave length only by the use of inductance and capacity *in series with each other*. For illustration we insert a diagram showing four forms of a tuned circuit:

[10] *Pickard*, III R. 2328–2335; *Tuska*, III R. 2498, Q. 107.

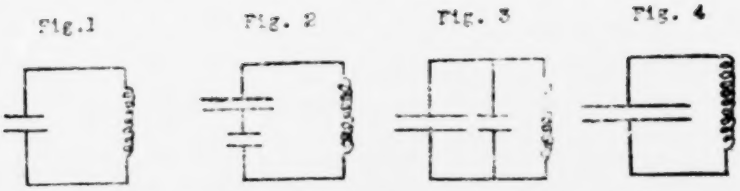


Figure 1 is the conventional tuned circuit containing inductance (the coil on the right) and capacity (the condenser, i. e., the parallel plates on the left) in series. Figure 2 shows two condensers in series with each other in the circuit, and sequentially in series with the inductance. In such case, the total capacity in the circuit is restricted to that of the smaller condenser, even if the larger condenser is so large as virtually to be a direct wire connection.[2] The third figure shows two condensers in parallel with each other in the circuit which is in series with the inductance. In that case, the total capacity equals the sum of the two capacities and the result is the same as if one larger condenser were used, as in the fourth figure. When these elementary concepts are applied to this case, it will be seen that Marconi's arrangement is the same and functions in the same way as the circuit in Figure 2, while the Government's arrangement is that of Figure 3.

(b) *Marconi's Circuit*

As the court below found (Finding XXXVI, I R. 30), in the open antenna-circuit connected at one end to an aerial wire and at the other end to the earth, the elevated wire and the surface of the

[2] Waterman, I R. 358; Tuska III R. 2509, X Q. 266, 268.

earth are respectively capacity areas and constitute the two plates of a condenser, with the air between acting as a dielectric (i. e., an electrical insulator between the two plates). Marconi's condenser *h* and the antenna-earth capacity (another condenser) are thus sequentially in series in the circuit which includes the inductance coil *g'*. (See Figure 2, p. 9.) Since the size of Marconi's condenser *h* is given as .0046 microfarads in the Marconi specification [12] and the antenna-earth capacity is established as .00024 microfarads,[13] the condenser *h* is so large with respect to the antenna-earth capacity that condenser *h* is almost like a continuous wire in this association. There is no dispute about this principle.[14] Consequently, in the Marconi arrangement, tuning of the circuit is accomplished by the inductance *g'* and the antenna-earth capacity. (See Figure 2, p. 9, *supra.*)

---

[12] P. 4, col. 3, under "receiving station."

[13] Wheeler, III R. 2437; Tuska, III R. 2509.

[14] Plaintiff's experts Waterman, Tuska, and Pickard each brought this out. Thus Waterman testified (I R. 358):

"It is a curious fact which must be borne in mind in dealing with wireless telegraph circuits that for the purposes of the high-frequency oscillatory currents a large condenser acts almost like a continuous wire, and when placed in a circuit in a series or tandem relation with a small condenser it has very little effect."

Tuska similarly testified (III R. 2509, XQ. 266) that the Marconi condenser *h*

"is so large that it can be neglected. When one has a very large condenser connected in series with a very small condenser, you can neglect the larger one."

See also Pickard, III R. 2330, 2331, 2334.

Since those skilled in the art understand that the antenna-earth constitute a condenser,[15] it is customary in diagrammatical drawings to omit symbolic representation of the capacity actually existing between the antenna and earth elements of the drawing. When this capacity is shown by symbol to aid its visualization, the complete antenna-circuit covered by claim 16, as shown in Marconi's Figure 2, is as shown on p. 19 (the dotted lines symbolizing the antenna-to-earth capacity):

The tuned circuit, therefore, is the heavy line circuit g', A, f' via antenna-earth capacity to E, and condenser h. Since for reasons already stated the condenser h acts substantially as a continuous wire, the effect of coil j' on the tuning of the antenna circuit is negligible.[16] Accordingly, the maximum wave length to which the tuned antenna circuit resonates is determined by the number of turns of inductance coil g', the variable inductance which Marconi stated to be the essential element for tuning his circuit.[17]

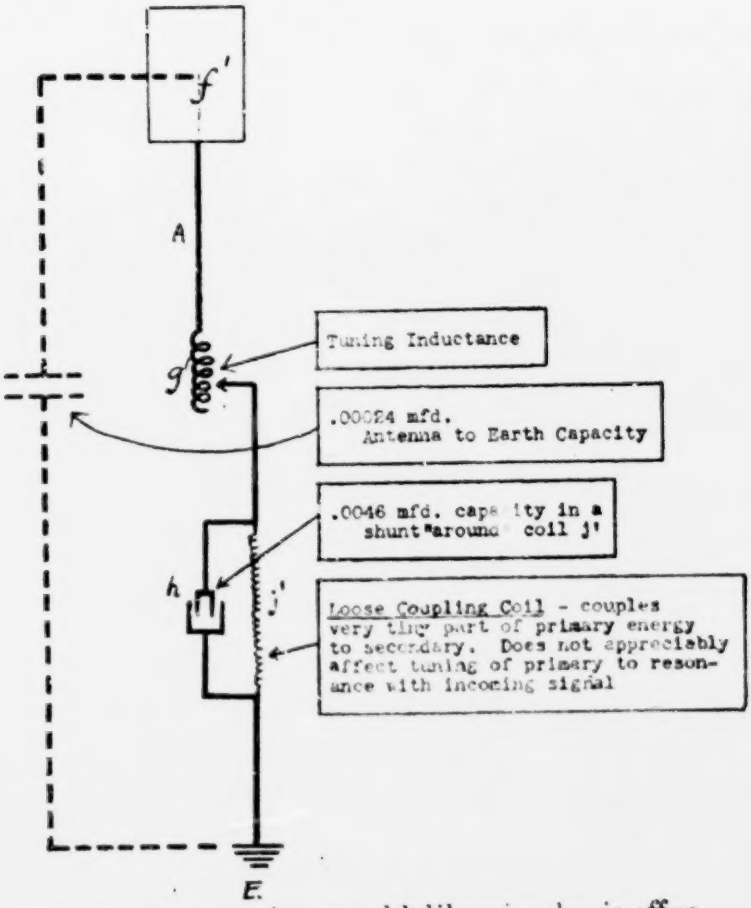
Condenser h cannot lengthen this wave length. Increasing its capacity would be ineffective since it is already so large compared to the antenna-earth capacity that only the latter capacity functions. Reducing the value of h to less than the

---

[15] This was recognized and explained by Lodge prior to the alleged Marconi improvement (Finding XXXVI, I R. 201).

[16] Tuska, III R. 2569; Waterman, I R. 378 (cf. Fig. 2, p. 16, *supra*).

[17] Marconi patent 763,772, p. 1, lines 56-59; Finding 19, I R. 156.



antenna-earth capacity would likewise be ineffective, for this would merely reduce the product of the capacity and inductance of the circuit, and so shorten the wave length.[18]

[18] The wave length to which a circuit resonates is determined by the product of the total effective capacity and the total effective inductance in the circuit. The accepted formula, used by all the experts, is: Wave length, in meters = $1884 \sqrt{L \times C}$, where L is inductance in microhenries, and C is capacity in microfarads (Lavender, III R. 2520).

The real function of the condenser *h* as used by Marconi, is to effect a "loose coupling" between the two receiver circuits to improve sharpness of tuning. There are two paths for the current flowing from antenna to earth: the condenser *h* and the coil *j'*. By placing his condenser *h* in the shunt arrangement described, Marconi caused substantially all of the current of the antenna circuit to flow through the condenser *h* and only about two percent to flow through the coil *j'*. The energy of the antenna circuit thus distributed to the shunt condenser *h* was "by-passed" *around* the primary coupling coil *j'* and hence not coupled to the secondary coil *j''*; only the small part of the energy (2%) running through the transformer primary coil *j'* was coupled to the secondary coil *j''*. By thus distributing only a small part of the energy to the transformer primary coil, the effect of one transformer circuit on the total energy of the other is reduced; that is, the coupling between the two circuits is made loose.[19] This loose coupling between *j'* and *j''* tends to give best results and sharpest tuning in Marconi's circuit. (See Findings XXXVIII, XXXIX; I R. 31, 32; II R.

[19] Loftin, II R. 977, 1073; Wheeler, III R. 2434–2437, 2442–2443, 2446–2448; Waterman, I R. 357.

1018, 1019, 1073.) [20] As already stated, the coil *j'* being substantially bypassed,[21] has as a practical matter no effect on the tuning of the primary circuit. The antenna circuit, as regards tuning, corresponds with Fig. 2, p. 16, *supra.*

(c) *The Government's Circuits*

In the Government's receivers the condenser, being differently connected (see figures, *supra,* p. 13), has an entirely different effect. Its capacity is added to the antenna-to-earth capacity and tends to increase the wave lengths. Moreover, it

---

[20] The energy could also be distributed and the coupling loosened either by relative physical movement of the transformer coils toward and from one another (Loftin Ex. M-2, Fig. 4) or by use of Stone's swamping inductances (*id.* Fig. 5). However, as pointed out by plaintiff's expert Waterman (I R. 373), the choice of these methods "is a mere matter of detail" in the combination. Marconi used his condenser *h* merely as another means of distributing the energy of the antenna circuit to effect loose coupling of the transformer circuits.

The trivial character of this feature of claim 16 is indicated by Waterman's testimony (I R. 357) that the "condenser *h* has no important or modifying effect on the general mode of operation" and by the unrebutted testimony of defendant's expert Loftin (II R. 977) that condenser *h* "is an arrangement rarely used in tuning the antenna or open circuit through varying the effect of the coil of the winding which it shunts," and is "merely one of the empirical methods employed by the art."

[21] Tuska, III R. 2509, 2168; Wheeler, III R. 2434–5, 55 Q.

does not serve to effect any loose-coupling arrangement.

As will be seen from the diagram above at page 13, the condenser (*h*) in the Government's receivers does not constitute a bypass around the coupling coil (*j'*), but instead is in parallel with all the inductance coils (*j'* and *g*) in the circuits and is thereby in parallel with the antenna-earth capacity (*f-E*). The presence of the two capacities thus in parallel in the circuit which is in series with the inductance gives a total capacity equal to the *sum* of the two capacities (Figs. 3 and 4 *supra*, p. 16). The result is the same as would be obtained if a larger antenna or increased inductance were used, with the additional effect that the current in the tuning coils is enabled to build up to a value even greater than that in the antenna.[22] In short, as the court below found after the accounting proceedings, the condenser in the Government's receivers enabled them to be tuned to longer wave lengths than would be the case with the ordinary series circuit and increased the sensitivity of reception (Findings 28, 29, and 45, I R. 143, 156).

The court below made no finding that the Marconi circuit was designed for this purpose or achieved this result, and the pertinent testimony

---

[22] This was known to the art prior to Marconi, as will be shown in Point II, pp. 24–31, *infra*.

was to the contrary.[23] The court simply found, in its interlocutory decision of November 5, 1935, that the Government's receivers had "apparatus coming within the terminology of claim 16" (Finding LXIII, I R. 60), and, in its final decision after the accounting proceedings, that the Government's condenser in the circuit employed "had the function and effect similar to that possessed by the adjustable condenser of the Marconi patent" (Finding 24, I R. 139) as to which it had made no specific finding.

The mere fact that the Government's arrangement falls within the literal language of claim 16 of course does not justify a finding of infringement;[24] and, as we have shown above, the "function and effect" of the two arrangements differ substantially. The court below failed to make any evidenciary findings of fact as to this very material issue. Had it made such findings, it would have been clear that the difference in arrangement, relative to the antenna-earth capacity and the tuning inductance, produces such a difference in mode of operation and result that no infringement can exist.

Point II

If the Government's receiver infringes claim 16, that claim is void for anticipation by the prior patents to Pupin and Fessenden

We have urged in Point I that the differences between the device disclosed in claim 16 and that in defendant's receivers are such as to preclude the conclusion that the latter infringed the former. If, however, we are mistaken in this, and claim 16 is broad enough to cover defendant's receivers, claim 16 is necessarily void because of prior patents.

The broad principles involved in tuning a receiver such as those of the Government involved in suit, were all known prior to Marconi. The evidence showed and the court below found that "the laws regarding the relationship of capacity and inductance to achieve the tuning of an alternating current circuit were known prior to Lodge" patent No. 609,154 (also in suit in the court below), which antedated the Marconi patent, and that Lodge taught the art to apply these laws to the so-called "open" antenna-circuit (Findings XXXVI, LXI; I R. 29–30, 57). The evidence also established and the court found that prior to Marconi's patent persons skilled in the art knew how to adjust the condensers shown in the earlier Stone patent No. 714,756 (Ex. Q–3) to achieve the

desired tuning, even though Stone's drawing did not show that his condensers were adjustable.[25]

In addition to these general principles, the prior art contained the precise arrangement utilized in the Government's receivers. The Fessenden patent No. 706,735,[26] for which application was filed in 1899, prior to the earliest date proven for the Marconi invention, showed an adjustable condenser in shunt with all the inductance coils in the antenna-circuit of a wireless receiver; and the Pupin patent No. 640,516,[27] also prior to Marconi, not only showed a similar arrangement, but fully explained the laws governing its operation, which were known at the time of Fessenden's application (Findings XXXVI, LIII, I R. 29–30, 47). It is our position, therefore, that since the arrangement of the condenser in the Government's receivers is the same as that disclosed prior to Marconi, the Marconi claim 16, if construed to apply to the Government's arrangement, is anticipated by the prior patents to Pupin and Fessenden, and as so construed is, therefore, void.

---

[25] Finding LIII, I R. 47–51; Finding XXVII, last sentence, I R. 24; Finding XLIII, 3rd paragraph, I R. 38–39; Finding LII, I R. 47.

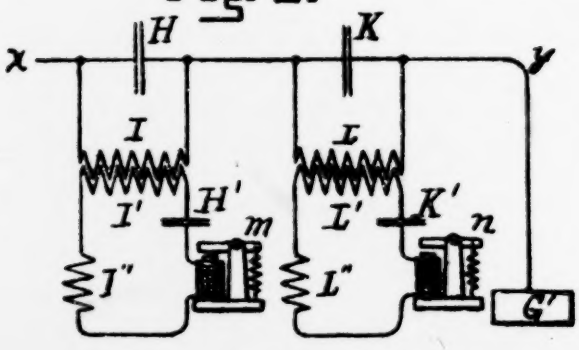
[26] Ex. LL, same as Plaintiff's Ex. 171, p. 90–97, in record prior to interlocutory decision of November 4, 1935, IV R. 3039.

[27] Ex. KK, same as Ex. U–2, V R. 3595. The latter exhibit was referred to by the court below as showing prior knowledge of the laws of tuning (I R. 30), and as prior art relied on as anticipating Marconi (Finding LI, I R. 45, 46).

1. Pupin

Upon an application of May 28, 1895, Pupin received patent No. 640,516 on January 2, 1900 (Ex. KK, U2), prior to Marconi's earliest invention date.[28] Figure 2 of this patent is as follows:

Fig. 2.



This Pupin patent discloses a receiving system in which an open receiving circuit *x*-*G'* connected to earth at *G'* is also connected to the primary coil *I* or *L* of an oscillation transformer, and to a condenser *H* or *K* in parallel with the primary coil. The secondary coil of the transformer (*I'* or *L'*) is in circuit with a suitable detecting device *m* or *n*.

In his drawing, Pupin's receiving system receives its oscillating current not from wireless waves as in Marconi's patent, but from a telegraph wire transmitting the alternating current and connected at *x*. However, Pupin contemplated applying the same technique to receiving oscillations transmitted by other means, as his specification points out:

[28] Nov. 10, 1900, Finding XLI, I R. 37.

> Where in the claims I specify the combination of a line-wire or a line with one or more resonant circuits * * *, I wish it to be distinctly understood that I do not limit myself to any specific means or method of transmitting from one station to another nor to any specific connection between the transmitting and receiving stations * * *. (Pupin patent, Def. Ex. U–2, p. 3, lines 64–73, V R. 3598.)

The immateriality of the mode of transmission, in this connection, is borne out by the fact that the effect upon Pupin's receiving apparatus is the same whether the oscillating current comes from the transmitter by wire or by way of electro-magnetic waves (Dow, III R. 2378–81; Loftin, II R. 938–941).

Pupin's patent explains (p. 1, lines 46–52) that if the circuit *H-I* (or *K-L*) is tuned to the same periodicity [28a] as the current in the wire *x–G'* (which corresponds to the antenna circuit and has the earth connection *G'*), the current flowing in primary coil *I* (or *L*) will be greater than that in the rest of the circuit (p. 1, lines 10–14), and hence will transmit maximum energy to the secondary coil *I'* (or *L'*) and in consequence to the operating coil of translating device *m* (or *n*). The Pupin specification (p. 1, lines 9–14) states:

[28a] As representative of any "desired frequencies" or periodicity, Pupin suggested 150 cycles and 250 cycles per second (Ex. U–2, p. 2, lines 70, 74, 107, V R. 3597). Maxwell's Laws apply to the full range of Hertzian wave frequencies including those, as was known in 1894, cf. Brief for United States in No. 369, this Term, footnote 14 and text pp. 36–37.)

> If a condenser be inserted in a line and a self-induction coil be connected in shunt with this condenser, then an alternating current impressed upon the line will under certain conditions be greater in the shunt-circuit than in the line itself.

The conditions under which this occurs are stated to be that—

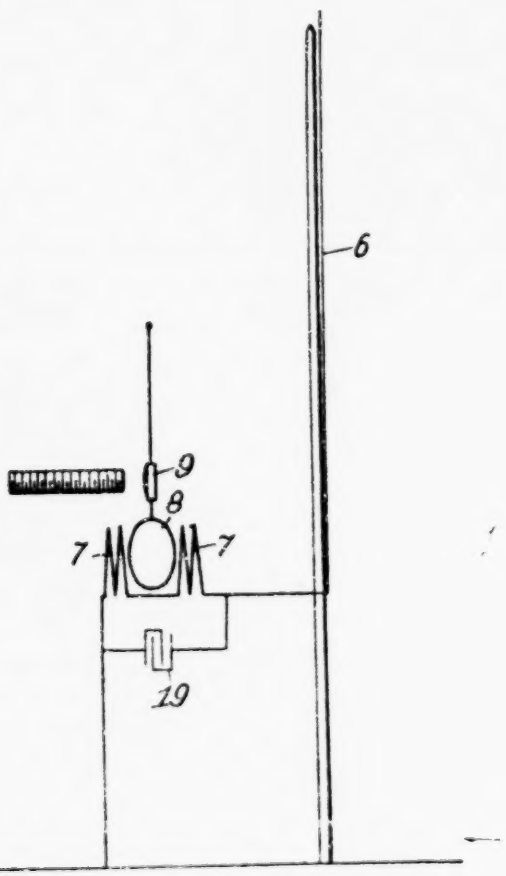
> the capacity of the condenser and the self-induction of the shunt-coil must be so related as to bring the shunt-circuit in resonance with the line-current. (P. 1, lines 33–36.)

It is thus clear that Pupin uses the condenser *H* or *K* (in parallel with the capacity existing between the elevated wire *x* and the earth *G'*) across all the inductance coils *I* or *L* of the circuit to be tuned to resonance with the incoming oscillation, and builds up the current in this resonant circuit to increase the sensitivity of reception.

The same operation and effect characterize the Government's receivers. These receivers use the condenser *h* in parallel with the antenna-earth capacity across all the inductance coils of the primary circuit, so that the two capacities add to each other, thus increasing the wave length, and building up the current in the primary transformer coil to improve the sensitivity of the receiver (Pickard III R. 2334; *supra*, n. 22, p. 22). The Government's arrangement, mode of operation, and result, are thus the same as those of Pupin.

2. Fessenden

The Fessenden patent uses the same arrangement as Pupin in a wireless-wave receiver. Upon application filed December 15, 1899, also prior to Marconi's invention date, patent No. 706,735 was granted August 12, 1902, to Fessenden (Ex. 171, p. 93, IV R. 3039; Ex. CCCC (not printed)). Figure 1 of this patent disclosed the following radio receiver:



This Fessenden receiver comprised an oscillation transformer consisting of a primary coil 7

and a movable secondary coil 8; an open circuit (6 to earth) connected with coil 7, the circuit including an oscillation receiving conductor 6 at one end and capacity (earth) at the other end; a condenser 19 in a shunt connected with the open circuit and around said coil 7; and a wave-responsive device 9 connected with the other coil 8.

As originally filed, the Fessenden application claimed, described, and illustrated this entire arrangement, comprising the open antenna circuit 6, the primary of which included inductance coils 7 shunted by a condenser 19 (Def. Ex. CCCC[235]). By amendment the purpose of this disclosure was stated to be the obtaining of a current in the shunt circuit greater than that in the antenna loa i or line by tuning the shunt or wheel circuit to resonance with the signals being received (*id.*). This purpose was the same, and the principles of operation of the shunt circuit were the same, as those disclosed in the earlier Pupin patent. Like Pupin's condenser *H*, Fessenden's condenser 19 is placed in parallel with the capacity existing between the antenna wire and the earth, and is connected across *all* the inductance coils of the circuit being made to resonate with the incoming wave length. This increases the wave length of resonance compared to that obtainable if the condenser were omitted, and tends to increase the current in such coils. The arrangement disclosed

[235] Not printed, see transcript.

and claimed, in light of the knowledge of the art, clearly suggested the amendment.[28c]

In defendant's receivers, just as in the Fessenden patent, the condenser *h* is placed in parallel with the antenna-to-earth capacity and is connected across *all* the inductance coils of the antenna circuit so that the two capacities add, in effect constituting one larger capacity acting in series with such tuning coils. The arrangement, mode of operation, and results achieved are thus identical.

Because of the correspondence between the defendant's structures and those disclosed in the pre-Marconi patents of Fessenden and Pupin, claim 16 of the Marconi patent, if construed to include the Government's structures, would necessarily include the identical prior art devices and hence be invalid for anticipation.[29] If claim 16 is to be saved from anticipation, it must be construed as directed solely to Marconi's specifically disclosed arrangement (*supra*, p. 16) and thus as having an operation and result different from the arrangement common to Fessenden, Pupin, and the defendant.[30] Such interpretation of claim 16

[28c] See authorities in Brief for United States in No. 369, this Term, footnotes 25 and 26 and text pp. 63–64.

[29] *Knapp* v. *Morss*, 150 U. S. 221; *American Fruit Growers, Inc.* v. *Brogdex Co.*, 283 U. S. 1.

[30] As shown in Point I (pp. 16–21, *supra*), such construction is entirely reasonable, since there is at least substantial evidence to support a finding that Marconi's condenser *h* is arranged differently, operates differently, and produces a different effect.

to avoid invalidity would, as we have shown in Point I, exclude the defendant's receivers and require a decision of noninfringement.

Point III

Evidence introduced at the accounting proceedings, bearing upon validity and infringement, should have been considered by the court below in rendering final judgment on those issues

In Points I and II, we have shown that there is no substantial evidence to support the conclusion of the court below that claim 16 was valid and infringed and, on the contrary, that the evidence required the opposite conclusion. To sustain our position we have treated the record as a unit and, accordingly, have cited pertinent portions not only of the hearing preceding the interlocutory judgment of November 4, 1935, but also of the hearing in the accounting proceedings which followed.[21] The basic evidence as to the structure of the Government's device, and its identity with that disclosed by Pupin and Fessenden, was introduced at the first hearing. We believe that the court below by a mere comparison of the drawings in Fessenden and Pupin's patents, which were prior to Marconi, and the drawings of the Government's receivers—all of which were in evidence at the earlier hearing—should have found at the close of that hearing that Marconi's claim 16, if infringed, was invalid for anticipation. Moreover, the court

[21] The record of the accounting proceedings begins at III R. 2313.

below made no evidentiary findings of fact whatever directed towards the criteria of infringement, to support its ultimate finding that there was infringement.[32] It is our position, therefore, that the record of the hearings preceding the interlocutory judgment alone requires the conclusion that claim 16 was not infringed, or if infringed, was not valid.

If we are mistaken in our contention that this conclusion can rest upon the earlier record standing by itself, it plainly is required by the entire record. And we submit that, in the circumstances of this case, the evidence which was required to determine the accounting issue may be, and should have been, considered by the court below upon the questions of validity and infringement. Since the question of the propriety of considering the evidence in the accounting proceeding turns upon the peculiarities of the development of this case, we shall first describe the course of events giving rise to the procedural problem.

The parties had stipulated that the first hearing be limited to the issues of validity and infringe-

---

[32] This alone would warrant reversal of the judgment under Section 3 (b) of the Act of February 13, 1925, as amended (see Appendix, p. 51, *infra*). Even before the amendment of May 22, 1939, § 3 (b) of the 1925 Act authorized this Court to "review, in addition to other questions of law, errors assigned to the effect that an ultimate finding or findings are not sustained by the findings of evidentiary or primary facts; or that there is a failure to make any finding of fact on a material issue."

ment, pursuant to Rule 39 of the Court of Claims which provides:

> In any patent suit it shall be competent for the parties to stipulate that the hearing in the first instance be limited to the issues of validity and infringement and when no such stipulation can be reached by the parties the court may order such procedure to be followed.
>
> If the patent is held valid and infringed by the United States the court shall so adjudge and the case shall thereafter proceed according to law.

At the first hearing, the operation and result of claim 16 were not brought out by either party, since both parties were proceeding on the assumption—plainly evident from the course of the hearing and the questions propounded to the expert witnesses—that claim 16 would stand or fall with the other six claims covering the receiver which the court below held to be invalid for anticipation. Claim 16 was a relatively minor aspect of these seven receiver claims, and was not given particular emphasis by either side (see n. 20, p. 21, *supra*) until the interlocutory judgment held that it alone out of the fifteen Marconi claims was valid and infringed. At the accounting, of course, both parties gave much more detailed attention to claim 16 and to the arrangement in the Govern-

ment's receivers alleged to infringe, as well as to similar devices in the prior art.[33]

After the first hearing, the court below rendered a judgment on November 4, 1935, holding claim 16 of the Marconi patent valid and infringed, but expressly reserving final judgment "until the amount of reasonable compensation for damages or profits is determined in accordance with the stipulation of the parties" (I R. 75).

The court below made findings of fact, but made no findings, either evidentiary or ultimate, concerning the mode of operation and results of Marconi's and the Government's arrangement to support its conclusion of infringement. And upon the assumption that this was due to the absence of evidence upon which such findings could be made, the conclusion as to infringement can be justified only as a preliminary or interlocutory determination prior to the accounting proceeding, and subject to reconsideration upon the final judgment after a full development of the evidence of infringement.

At the accounting proceedings, in order to establish the amount of compensation to which

---

[33] The Commissioner of the Court of Claims who reported proposed findings of fact to the court at the conclusion of the first hearing, specifically mentioned the absence of evidence in the record as to the mode of operation and result of the condenser described in Claim 16. *Record Ct. Cl.* No. 33,642, Proposed Finding of Fact LXII, June 26, 1933, p. 2216.

the plaintiff was entitled, plaintiff adduced evidence to show the advantages derived by the Government from its alleged use of the device disclosed in claim 16. In order to establish a basis for a proper apportionment of value, evidence was then introduced by the Government to show that the proven advantages were derived not from the Marconi arrangement but from the Fessenden and Pupin prior art disclosures. These advantages necessarily inhered in the mode of operation and the results attained by the devices involved, and to justify their inclusion in the award, their attribution to the Marconi claim was of course requisite. Consequently, evidence was fully developed at the accounting proceedings showing the actual operation and effect of the condenser arrangements disclosed by Marconi, and Pupin and Fessenden, and of that which was employed in the Government's receivers.

At the close of the accounting proceedings, and upon the basis of the entire record, the Government requested the court to make numerous evidentiary findings of fact as to the mode of operation of the Marconi and the Government's devices and of the devices disclosed by Pupin and Fessenden,[34] and also requested the ultimate finding that—

---

[34] Defendant's exceptions to the commissioner's report on the accounting (Record in C. Cls. No. 33642, pp. 4719–4799).

> the mode of connecting the primary condenser in parallel with the antenna-to-earth capacity used by the defendant followed the disclosure of [Pupin and Fessenden], and hence does not infringe the Marconi claim 16 which is based upon a different arrangement, operating in a different manner to obtain a different result.[32]

The court, however, declined to make any additional findings on the issues of validity and infringement, holding that the—

> question of infringement of Marconi claim 16 by the apparatus designated in Finding LXIII of the prior decision is not before us in the present accounting. In order to forestall further controversy, however, we have found validity and infringement as an ultimate fact (Findings 1 and 23) in our special findings of fact. (I R. 176.)

The court further stated in its opinion that its original decision "established the scope of claim 16 when it held the same infringed," and that the

> sole purpose and function of an accounting in a patent infringement case is to ascertain the amount of compensation due, and no other issue can be brought into the accounting to change or alter the court's prior decision. (I R. 177.)

In failing to make the requisite evidentiary findings of fact to support its conclusions as to

---

[32] Record in C. Cls. No. 33642, p. 4799.

validity and infringement, and in declining to consider the evidence adduced at the accounting proceeding bearing upon these issues, we believe the court below was in error. The judgment of November 4, 1935, was interlocutory in nature, the court below having expressly reserved final judgment until after the accounting I R. 75; consequently, the court had full power to modify it in order to accord with the entire record at the close of the proceedings. A decree holding a patent to be valid and infringed and ordering an accounting proceeding before a master is not a final decree, but merely interlocutory, even though accompanied by a permanent injunction. *John Simmons Co.* v. *Grier Bros. Co.*, 258 U. S. 82; see *McGourkey* v. *Toledo & O. C. Ry.*, 146 U. S. 536, 545.[38] Consequently, the court may modify such a decree after the accounting proceedings, in rendering final

[38] While there was originally no right to appeal from an interlocutory decree of a federal court holding a patent valid and infringed and referring the matter to a master for an accounting (*Barnard* v. *Gibson*, 7 How. 649; *Humiston* v. *Stainthorp*, 2 Wall. 106), the Act of March 3, 1911, as amended (28 U. S. C. § 227a), now permits appeals from such decrees. Similarly, an interlocutory judgment of validity and infringement by the Court of Claims is reviewable prior to the accounting proceedings on a writ of certiorari from this Court. *United States* v. *Esnault-Pelterie*, 299 U. S. 201; 303 U. S. 26. But review at this stage is permissive only; and defendant may wait until final judgment, as in the case at hand. This also holds true in the district courts. *Bingham Pump Co.* v. *Edwards*, 118 F. (2d) 338 (C. C. A. 9).

judgment. *Bingham Pump Co.* v. *Edwards*, 118 F. (2d) 338 (C. C. A. 9); see *John Simmons Co.* v. *Grier Bros. Co.*, 258 U. S. 82, 88, 89; *Individual Drinking Cup Co.* v. *Errett*, 297 Fed. 733, 741 (C. C. A. 2); *David Bradley Manuf'g Co.* v. *Eagle Manuf'g Co.*, 57 Fed. 980, 985 (C. C. A. 7), certiorari denied 154 U. S. 500; *Bassick Mfg. Co.* v. *Larkin Automotive Parts Co.*, 23 F. (2d) 92 (D. C. N. D. Ill); *cf. McGourkey* v. *Toledo & O. C. Ry.*, 146 U. S. 536 (mortgage foreclosure); *Perkins* v. *Fourniquet*, 6 How. 206, 208 (distribution of property to heirs).

The reason and policy underlying these principles make them as fully applicable to a patent proceeding in the Court of Claims where an accounting involving such judicial questions as apportionment and evaluation follows a preliminary determination as to validity and infringement, and requires further proceedings in the Court of Claims upon such questions. *Cf. McGourkey* v. *Toledo & O. C. Ry.*, 146 U. S. 536, 545. Since the Court of Claims retained power to modify its preliminary determination as to validity and infringement, and since the record before the court on the accounting clearly contained evidence requiring a finding of nonfringement (i. e., differences in mode of operation and result), the court below erred in considering itself bound by its initial and preliminary judgment as to validity and infringement.

This conclusion is not inconsistent with the conceded general rule that the court's power to modify

an interlocutory conclusion does not justify the master or commissioner in admitting, in the accounting proceedings, evidence designed *solely* to attack the court's interlocutory holding of validity and infringement. *Flat Slab Patents Co.* v. *Turner,* 285 Fed. 256 (C. C. A. 8), certiorari denied 262 U. S. 752. For the very existence of the power to modify assumes that evidence or other matter bearing upon the validity of the interlocutory order may subsequently come to the court's attention and justify modification of that order. *Cf. John Simmons Co.* v. *Grier Bros. Co.,* 258 U. S. 82; *Bingham Pump Co.* v. *Edwards,* 118 F. (2d) 338 (C. C. A. 9). This case squarely presents the occasion for the exercise of that power, because the very issues left for ultimate judicial determination after the interlocutory judgment required the consideration of evidence which demonstrated the error in the earlier conclusion.

Point IV

The Court of Claims erroneously adopted as a basis of compensation advantages attained by the Government's receivers, but not attainable by Marconi's device

After its interlocutory judgment of November 4, 1935, holding claim 16 valid and infringed, the court below ordered an accounting proceeding to be held before a Commissioner, in order to determine the "reasonable and entire compensation" to which the plaintiff was entitled under the Act of June 25, 1910, as amended (I R. 75; see Appendix, pp. 51, 52). In the accounting pro-

ceeding, the Commissioner found it necessary to employ, as the basis for compensation, the value of the advantages contributed to the Government structures by the subject matter of Marconi claim 16, measured for the most part by the cost of obtaining such advantages through alternative constructions. The court below adopted this basis (I R. 180–181). It thus became necessary first to determine what advantages were derived from the Marconi contribution, as distinguished from the contributions of others.

Plaintiff proved, and the court correctly found (Findings 29, 30; I R. 143–144), that *defendant's* arrangement of the condenser in its circuit (1) increased the wavelength range of the receiver; (2) saved the space and weight of additional loading coils; and (3) increased the current in the primary coil of the oscillation transformer, thus improving sensitivity. Plaintiff made no effort to show that the arrangement disclosed by Marconi's patent had any of these advantages. Defendant then introduced evidence showing that the condenser arrangement disclosed by Marconi had none of these advantages;[37] and that on the

[37] Marconi's arrangement of the condenser, as explained above in detail, put it in series with the antenna-to-earth capacity where it could not operate to increase the wavelength range of the receiver. Marconi actually increased his wavelength range by using additional loading coil q' (see n. 39, p. 47, *infra*, and compare tunes 3 and 4 in the table on page 4 of the Marconi patent) and thus did not save the space and weight of these additional coils. Again, in Mar-

contrary the advantages of the Government's condenser arrangement were those realized in the same way in Fessenden's and Pupin's prior inventions.[38]

Defendant requested, both before the Commissioner and the court below, that evidentiary findings be made not only as to the advantages of the Government's condenser arrangement, but also as to whether the advantages were achieved by the arrangement disclosed by Marconi, or by the earlier arrangements of Pupin and Fessenden, as a basis for determining which of the proven advantages, if any, of defendant's structure had been derived from the Marconi disclosure. The defendant further asserted, before both Commissioner and court, that none of the proven advantages of defendant's arrangement was derived from the Marconi disclosure; hence, that even if claim 16 was valid and infringed, plaintiff was

---

coni's arrangement the condenser did not operate to increase the current in the primary coil of the oscillation transformer, but on the contrary operated to reduce it to only about 2% of what it would have been in a straight series connection. (See pp. 20, 21, *supra*.)

[38] The Pupin and Fessenden patents concerned were in evidence prior to the court's interlocutory decision of November 4, 1935 (Def. Ex. U–2; Pl. Ex. 171, p. 98, *et. seq.*). These patents were prior to Marconi in point of time and disclosed the feature of defendant's arrangement alleged to infringe claim 16. Hence, as shown in Point II (pp. 24–39, *supra*), Pupin and Fessenden anticipate and invalidate the claim if it applies to defendant's arrangement.

entitled to nominal damages only (see n. 34, p. 36, *supra*).

The court below made evidentiary findings of fact as to the mode of operation and advantages of the defendant's structure, but refused to consider or make findings based on evidence adduced by the Government explaining the functions of the condenser in the Marconi arrangement and showing that the advantages of the Government's device were not contributed by the Marconi disclosure. Instead, the court used the advantages achieved by the Government's arrangement as the basis for compensation, without finding that Marconi's arrangement contributed such advantages (I R. 175–178).

It measured the value of the increased wavelength range by the cost of the additional inductance coils which would have been necessary to attain that advantage without employing the Government's condenser arrangement, and found that the cost of such additional coils would have been $56,113.17. It further found that the other minor advantages attained by the Government's arrangement of the condenser (increased sensitivity and the saving in space and weight resulting from eliminating the necessity of such extra coils) were worth $2.50 per receiver, or a total of $10,017.50. Of the total amount of $66,130.67 taken to represent the advantages of defendant's arrangement,

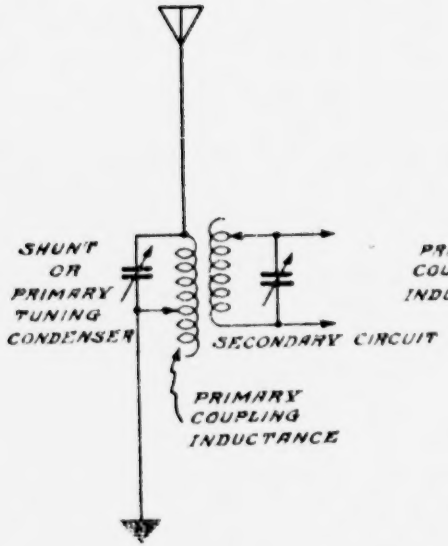
the court below allowed the plaintiff 65%, or $42,984.93 with interest thereon, advancing no explanation for the percentage selected (I R. 151–157).

We submit that in the absence of any finding—or of any evidence which would support a finding—that the evaluated advantages were contributed by plaintiff's patent, the ruling of the court below as to compensation was in error.

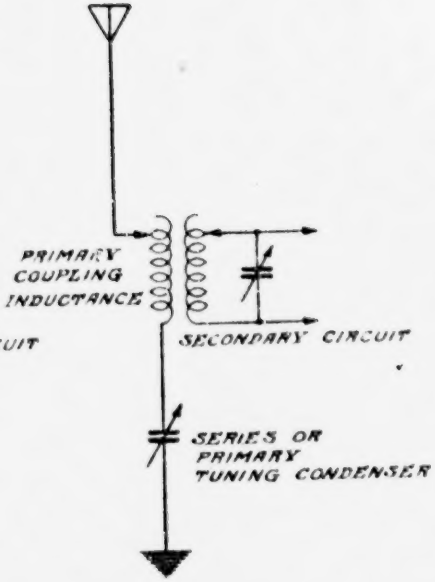
1. The court made findings as to the advantages of defendant's device only

In its final findings of fact, the court below explained (Finding 27, I R. 141–142) by means of diagrams reproduced hereafter, that with the inductance and capacity of the circuit in series with the antenna-earth capacity (middle diagram), regardless of the maximum value of the condenser, no longer wave length can be received than could be received without the condenser; and that the wave-length range can be increased by adding more inductance, as by a loading coil (right diagram), as well as by a shunt-connected condenser bridging all the inductance coils in the circuit (left diagram, called "Parallel Connection"):

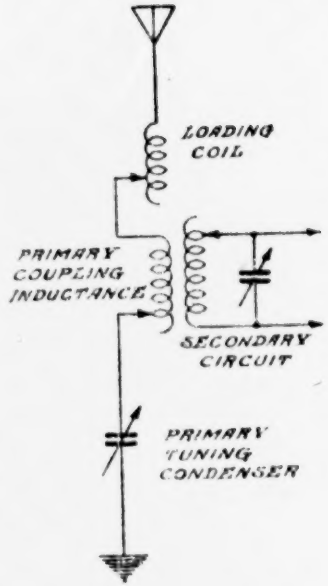
But the parallel connection shown is not the arrangement of the Marconi circuit, for it omits Marconi's adjustable inductance g' between the



PARALLEL CONNECTION



SERIES CONNECTION



SERIES CONNECTION
WITH LOADING COIL

condenser and the antenna which Marconi claimed as part of the "means for adjusting the two transformer-circuits in electrical resonance with each other," and which he stated to be "essential" (see note 7, p. 12, *supra*, and Fig. 2 of Marconi patent, page 9, *supra*). The shunt-connected condenser shown in the court's diagram is rather that of the Government's circuit, which differs in arrangement, operation, and result from that of Marconi, as shown in points I and II (pp. 12–31, *supra*).

The court below properly found that the condenser *h* in the defendant's receivers "enables the primary circuit to be tuned to the relatively longer wavelengths" when the condenser is shifted to the so-called "parallel connection" (Finding 28, I R. 143). But there is no finding nor any indication in the court's opinion that any connection of the Marconi condenser *h* "enables the primary circuit to be tuned to the relatively longer wavelengths."

The court properly attributed to defendant's arrangement the other and minor advantages of saving in space and weight and increase in sensitivity, resulting from attaining longer wavelength without additional loading coils (Findings 29, 30; I R. 143–4). But here again there is no finding, nor any indication in the court's opinion, that the arrangement of the condenser disclosed by Marconi accomplished these advantages.

2. The record shows that the advantages found for defendant's arrangement were not contributed by Marconi

As shown just above, all the advantages found for defendant's arrangement of the condenser were based on the fact that defendant's arrangement enabled longer wavelengths to be attained without the use of additional loading coils, and hence without the added cost and disadvantages of such coils; but the court made no finding that the arrangement necessary to attain these advantages was disclosed in the Marconi patent.

As shown in Point I (*supra*, pp. 12–23), Marconi arranged his condenser *h* (upon which claim 16 is based) in such a manner that it did not and could not operate to increase the wavelength, or to eliminate the necessity for additional loading coils to increase the wavelength. Indeed, when he used that condenser arrangement, he relied entirely on additional load coils to increase the wavelength.[39]

It is thus clear that Marconi's arrangement of the condenser did not attain the major advantage

[39] It will be seen from the table on page 4 of the Marconi patent that when Marconi desired to increase the wavelength of resonance of the circuit employing the condenser *h* (tunes 3 and 4) he added more loading coils *g'* (tune 4) than were used in tune 3. He did not eliminate their use. Marconi did not change the adjustment of his condenser *h* when he changed from tune 3 to tune 4 in the table on page 4 of his patent, and indeed to have done so could only have decreased the wavelength, as his condenser *h* was arranged to operate in series with the antenna-to-earth capacity. (See Point I, *supra*, p. 12–21.)

of an increased wavelength, nor the other advantages dependent on elimination of additional loading coils.[40] It follows that the advantages found for defendant's arrangement were not contributed by the Marconi disclosure.

3. The advantages of the defendant's arrangement were contributed by the earlier Pupin and Fessenden disclosures

The record shows that the advantages found to inhere in the Government's arrangement, far from being derived from Marconi, were in fact attributable to the disclosures of Pupin and Fessenden, which were prior to Marconi.

The court below found that after Lodge's disclosure, those skilled in the art were informed that the laws of resonance set forth in Pupin's patent were applicable to the so-called open antenna-circuits of wireless apparatus.[41] And as shown in Point II, above, the Pupin patent and the patent to Fessenden both showed, prior to Marconi's patent, the arrangement of the condenser in parallel with the antenna-to-earth capacity, as it was employed by defendant. This arrangement, by the laws of resonance known prior to Marconi's contribution,[42] caused the condenser capacity to be

---

[40] Moreover, as shown under Point I, Marconi's arrangement served to decrease the current in the coupling coil *j'* as compared to that in the antenna, and not to increase the current in the coil, as did defendant's arrangement (p. 20, *supra*).

[41] Finding XXXVI, I R. 29–30. Indeed, the Pupin patent itself had so indicated (see quotation from Pupin patent, p. 27, *supra*).

[42] Finding XXXVI, I R. 29–30.

added to the antenna-to-earth capacity, thus (as compared to a circuit having no such condenser) both increasing the wave length and increasing the current in the primary coil of the transformer, all without the necessity of additional loading coils.

Since these earlier patents contributed the advantages found by the court below, and did so by the same means as were used by defendant, these advantages could not have been contributed by Marconi's disclosure, as they had already been disclosed to the art.

4. The court below contravened settled rules of law governing apportionment in patent accounting

It is settled that a plaintiff in infringement is entitled to recover from the defendant only the value contributed by his patented device. *Dowagiac Mfg. Co.* v. *Minneapolis Moline Plow Co.*, 235 U. S. 641; *Westinghouse Co.* v. *Wagner Co.*, 225 U. S. 604, 615; *cf. Sheldon* v. *Metro-Goldwyn Pictures Corp.*, 309 U. S. 390; *Mason* v. *Graham*, 23 Wall. 261, 277; *Egry Register Co.* v. *Standard Register Co.*, 23 F. (2d) 438 (C. C. A. 6).

As we have shown, the advantages of longer wavelength range and greater sensitivity in the Government's receivers, insofar as derived from the condenser arrangement in question, were contributed not by Marconi's disclosure upon which claim 16 is based, but exclusively by Pupin, Fessenden, and the Government. Since it had no part in creating these advantages, Marconi's patent can furnish no basis for any participation in

their value. In holding otherwise, the court below contravened the settled rules of accounting in infringement proceedings.

CONCLUSION

For the foregoing reasons the judgment of the Court of Claims with respect to claim 16 of the Marconi patent 763,772 should be reversed.

Respectfully submitted.

APPENDIX

The Act of June 25, 1910, c. 423, 36 Stat. 851 (35 U. S. C. § 68), provided:

> That whenever an invention described in and covered by a patent of the United States shall hereafter be used by the United States without license of the owner thereof or lawful right to use the same, such owner may recover reasonable compensation for such use by suit in the Court of Claims: * * * *Provided further*, That in any such suit the United States may avail itself of any and all defenses, general or special, which might be pleaded by a defendant in an action for infringement, as set forth in Title Sixty of the Revised Statutes, or otherwise * * *.

This was amended by the Act of July 1, 1918, c. 114, 40 Stat. 704, to read as follows:

> That whenever an invention described in and covered by a patent of the United States shall hereafter be used or manufactured by or for the United States without license of the owner thereof or lawful right to use or manufacture the same, such owner's remedy shall be by suit against the United States in the Court of Claims for the recovery of his reasonable and entire compensation for such use and manufacture: * * * *Provided further*, That in any such suit the United States may avail itself of any and all defenses, general or special, that might be pleaded by a defend-

> ant in an action for infringement, as set forth in title sixty of the Revised Statutes, or otherwise * * *.

Section 3 of the Act of February 13, 1925, c. 229, 43 Stat. 936, 939, as amended by the Act of May 22, 1939, c. 140, 53 Stat. 752 (28 U. S. C. § 288*b*), provides:

> (b) In any case in the Court of Claims, including those begun under section 180 of the Judicial Code, it shall be competent for the Supreme Court, upon the petition of either party, whether Government or claimant, to require, by certiorari, that the cause be certified to it for review and determination of all errors assigned, with the same power and authority, and with like effect, as if the cause had been brought there by appeal. In such event, the Court of Claims shall include in the papers certified by it the findings of fact, the conclusions of law, and the judgment or decree, as well as such other parts of the record as are material to the errors assigned, to be settled by the Court.
>
> The Court of Claims shall promulgate rules to govern the preparation of such record in accordance with the provisions of this section.
>
> In such cases the Supreme Court shall have authority to review, in addition to other questions of law, errors assigned to the effect that there is a lack of substantial evidence to sustain a finding of fact; that an ultimate finding or findings are not sustained by the findings of evidentiary or primary facts; or that there is a failure to make any finding of fact on a material issue.

OCTOBER TERM, 1942

No. 373

THE UNITED STATES,

Cross-Petitioner,

v.

MARCONI WIRELESS TELEGRAPH COMPANY OF AMERICA,

Cross-Respondent.

BRIEF FOR CROSS-RESPONDENT IN OPPOSITION TO CROSS-PETITION FOR WRIT OF CERTIORARI

Statement

A considerable number of the statements set forth in cross-petitioner's petition and argument are controverted by cross-respondent (plaintiff).[1] Reference is made to plaintiff's brief in support of its own petition (in case No. 369) and to the argument herein, for statements of plaintiff's position on some of these points.

For purposes of the cross-petition, we desire to call this Court's attention to the following additional facts:

The case was originally heard before the Court of Claims under a stipulation "that the issue of reasonable

[1] To avoid confusion, we will hereinafter refer to the parties as "plaintiff" and "defendant", rather than as "cross-respondent" and "cross-petitioner".

compensation or damages and profits be postponed until the *determination* by the court of the issues of validity and infringement of the various patents in suit.'"[2] (Finding LXXXIII of November 4, 1935; R., pp. 74-75.) Following this stipulation, the 1935 interlocutory judgment of the Court of Claims held that claim 16 of Marconi patent No. 763,772 was valid and had been infringed and that plaintiff was entitled to compensation for defendant's use of the subject matter thereof. (R., p. 75.) Defendant made no motion for a new trial with respect to this decision; recognized, in statements made to the Court of Claims, that the claim had been held valid and infringed; and permitted plaintiff to expend a large amount of time and money to prove the amount of compensation to which the Court of Claims had held that it was entitled.

In the course of the accounting proceeding, defendant, on the supposed issue that certain radio receivers not specifically covered by the interlocutory decision of the court below differed from those named therein as infringing devices,[3] offered a large amount of highly technical and, in a number of respects, contradictory evidence which, it now appears, was in reality directed to the issues of validity and infringement. This testimony (together with some offered on behalf of the plaintiff) appears at pages 2313 to 2522 of the transcript of record.

As these issues of validity and infringement had already been determined by the Court of Claims, in accordance with the stipulation of the parties, plaintiff was not called upon to meet this new evidence directed to these issues. For the reasons stated by the court below in its opinion (R.,

---

[2] Emphasis throughout this brief is ours.

[3] This issue was later shown, and is now recognized by defendant, to have been false.

pp. 175-178), this evidence had no place in the record on the accounting proceeding: it would have been excluded by the Commissioner if offered for the purpose for which defendant now seeks to use it, namely, to secure a reversal of the interlocutory decision of validity and infringement.

On the final hearing before the Court of Claims, defendant devoted a large share of its argument and briefs to the question of whether the interlocutory judgment of that court, holding that claim 16 was valid and had been infringed by defendant, was correct. The argument was based (as is the argument before this Court) almost entirely on evidence submitted by defendant on the accounting proceeding.[4]

Summary of Argument

Plaintiff submits: (1) that a review by this Court of the decision of the court below with respect to other claims of Marconi patent No. 763,772 will give no occasion for a review of the decision with respect to claim 16 of that patent; (2) that, under the circumstances of the present case, the issues of validity and infringement of claim 16 must be determined on the evidence that was before the court below when it decided those issues in its interlocutory judgment, or, in the alternative, the case should be remanded for additional evidence and findings; (3) that there was no error in the decisions below with respect to that claim; and (4) that those decisions involve no conflict with prior decisions of this or other courts.

---

[4] The only testimony on the original trial to which defendant now refers in support of its argument is that of Waterman (R., pp. 357-358) and Loftin (R., p. 977). Neither of these references supports defendant's present argument. (See pp. 7-8, *infra*.)

ARGUMENT

POINT I

A Review of the other Claims of the Marconi Patent will Give no Occasion for a Review as to Claim 16

Neither of the reasons set forth by plaintiff in its petition in case No. 369 for this Court's reviewing the decision below with respect to the other claims of Marconi patent No. 763,772 applies to the decision that claim 16 was valid and infringed. This decision was not in conflict with prior decisions: it was in accord with them (see Point IV, *infra*). Furthermore, to reduce or take away plaintiff's recovery for defendant's use of the subject matter of that claim would not alleviate the failure of justice: it would aggravate it.

Defendant suggests that a review of the other claims would involve a consideration of claim 16 "so far as it covers four-circuit tuning" (cross-petition, p. 11). However, claim 16 has an added feature (the parallel condenser), not present in any other claim, and is a specific claim differing from all the others in this respect. As the court below held that that feature distinguished the claim from those broadly directed to "four-circuit tuning", a review of the correctness of the decision as to the other claims would not involve consideration of this distinguishing feature of claim 16.

POINT II

It would be Contrary to Orderly Practice to Review, on the Basis of Evidence Adduced by Defendant on the Accounting Proceeding, the Decision of the Court of Claims as to Validity and Infringement of Claim 16

In accordance with usual practice in equity cases, as embodied in Rule 39 of the Court of Claims, and in ac-

cordance with the stipulation of the parties, entered into pursuant to that Rule (see pp. 1-2, *supra*), the issues of validity and infringement of claim 16 were determined by the interlocutory judgment of the Court of Claims. In the absence of a reopening of these issues by the trial court, plaintiff was entitled to consider that the issues were no longer open before that court.

Although the doctrine of "law of the case" is only a rule of practice and the Court of Claims had the power to reconsider the issues, yet the rules of that court (providing for a stipulation such as was here entered into and also for a timely motion for a new trial and amendment of the findings) specify the practice to be followed for the redetermination of issues once decided and show clearly that it is the practice of that court to *determine* the issues of validity and infringement before ordering an accounting to ascertain the extent of plaintiff's damages.[5]

If defendant had desired to submit additional evidence on those issues or reargue the question, the proper procedure would have been to make a motion for a new trial and for amendment of the findings. No such motion was made. Instead, defendant chose to offer *new* evidence on issues already determined and to offer it on the accounting

---

[5] Rule 39 of the Court of Claims and the pertinent part of Rule 91 are set forth in the Appendix (*infra*, p. 11).

This practice, as to the finality of interlocutory judgments on the issues of validity and infringement of a patent, is not confined to the Court of Claims. See *Flat Slab Patents Co.* v. *Turner*, 285 Fed. 257, 273 (C. C. A., 8th Circ.; certiorari denied, 262 U. S. 752); *Timius Olsen Co.* v. *Baldwin-Southwark Corp.*, 25 F. Supp. 885, 886.

proceeding—thereby avoiding the necessity of applying to the court for permission to place such evidence before it.[6]

(a) We respectfully submit that it would be a dangerous precedent to consider here the evidence adduced on the accounting proceeding and thus to approve the procedure adopted by defendant. If the issues determined by an interlocutory decree can be attacked before a referee or master in the same case, without permission of the court which entered the decree, the very purpose of interlocutory decrees and of subsequent references to referees or masters to determine subsidiary questions would be undermined and the function of interlocutory decrees largely nullified.

(b) If the findings of the Court of Claims that claim 16 of Marconi patent No. 763,772 was valid and infringed are not to be accepted by this Court, then, we submit, there are two considerations which should require this Court to remand the case to the lower court for additional evidence and findings on these issues. These two considerations are as follows:

(1) As defendant assigns as error the alleged failure of the Court of Claims to make certain findings of fact (Cross-petition, p. 10), and as it is not the function of this Court to make basic findings of fact, the case should be remanded for such findings. *Seminole Nation* v. *United States*, 316 U. S. 286, 300.

(2) As plaintiff properly considered that the issues of validity and infringement of claim 16 were closed, it made no real effort to meet the new evidence which defendant now seeks to use to secure a reversal of the interlocutory

[6] As stated above, the evidence was offered and admitted before the Commissioner on the accounting proceeding on a theory later admitted to be without foundation.

judgment. If such evidence were now to be considered on the issues of validity and infringement, it would mean that those issues would be determined on evidence adduced by defendant to which plaintiff has not replied in full.

We respectfully submit, however, that the questions involved with respect to claim 16, both as to validity, infringement, and recovery, are not of sufficient public or legal importance to warrant the additional time, labor, and money that would necessarily be involved, both before this Court and before the Court of Claims, either in a review or a remand of these issues.[7]

POINT III

There was no Error in the Decision of the Court of Claims in so far as Defendant Seeks Review Thereof

The only evidence to which defendant refers, that was before the Court of Claims when it held that claim 16 of the Marconi patent was valid and infringed, is that of Waterman (R., pp. 357-358) and Loftin (R., p. 977). (Cross-petition, p. 8.) All that Waterman there said was that the parallel condenser of the patent "has no important or modifying effect on the *general mode of operation*",— *i. e.*, on the tuning of the four circuits together.[8] All that Loftin said was that the parallel condenser was an arrangement "used in *tuning* the antenna or open circuit through vary-

---

[7] In this connection, it should be remembered both that the decision is in accord with prior decisions on that claim (see Point IV, *infra*), and that the patent has expired so that plaintiff will not hereafter be able to assert this claim against any other party.

[8] The testimony on R., p. 358 deals with the condenser *h'*, which is in a different circuit.

ing the effect of the coil of the winding which it shunts" and that it was "one of the 'empirical' methods employed by the art." Neither of these statements either supports or suggests defendant's present argument as to the mode of operation of the Marconi circuit.

Defendant fails to refer to Water man's testimony (R., pp. 356-357, 389-390) that the parallel condenser is inserted "as a further means of tuning the circuit", and that the parallel connection of the antenna tuning condenser in defendant's receivers shown in Plaintiff's Exhibits 79 and 95 constituted the arrangement of Figure 2 of the Marconi patent—the figure upon which claim 16 was based. These statements were not controverted by any of defendant's witnesses. They were accepted by the Court of Claims and infringement of that claim by those receivers was found (Finding LXIII, R., p. 60).

The Fessenden and Pupin patents, primarily relied upon before this Court by the defendant, were both introduced in evidence prior to the interlocutory judgment.[2] But defendant did not *then* consider these patents of sufficient importance with respect to claim 16 to attempt to show, either by testimony or by argument, that they invalidated or limited the scope of the claim.

On the other hand, defendant's witness Stone (whose early disclosures were held by the Court of Claims to have invalidated the *other* claims of this Marconi patent) said (R., pp. 819-820):

> "The first *very clear and complete exhibition* of the use of a continuously variable tuning condenser in shunt to the primary of a transformer in a wireless telegraph receiver, so far as I am aware, is contained

[2] The Fessenden patent No. 706,735 was a part of plaintiff's Exhibit 171 and the Pupin patent No. 640,516 was defendant's Exhibit U-2.

in the specifications and drawings of the English patent to Marconi, No. 7777, of 1900."

This English patent[10] referred to by Stone corresponded with Marconi's United States patent No. 763,772 and Figure 2 thereof was identical with Figure 2 of the American patent. The shunt condenser described by Stone constitutes the distinguishing feature of claim 16.

We respectfully submit that, on the basis of the record before the Court of Claims, there was no error in its decision that claim 16 of Marconi patent No. 763,772 was valid and infringed.

POINT IV

There is no Conflict, as to Claim 16, between the Decisions of the Court of Claims and Prior Decisions of this or other Courts

As all prior courts which had considered the validity and infringement of claim 16 had held the claim valid and, with one exception, infringed,[11] the decision of the Court of Claims was not in conflict with any of these prior decisions.

---

[10] Plaintiff's Exhibit 34, included in the exhibits certified as incorporated in the findings of the court below.

[11] See the cases cited at pages 4-5 of our petition in case No. 369. The exception, as to infringement, is *Marconi Wireless Telegraph Company* v. *Kilbourne & Clark Mfg. Co.*, in the Ninth Circuit. (See our petition for certiorari, p. 5, and supporting brief, pp. 16-17, 28.) In that case, claim 16, together with all the other claims in suit of the Marconi patent, was held valid but not infringed—not for the reason here urged by defendant, but because, in that court's opinion, the apparatus there claimed to infringe did not utilize the principle of four-circuit tuning.

The Court of Claims found (R., p. 139; Finding 24) that

> "The adjustable condenser in such a circuit [the circuit of defendant's receivers] had the function and effect similar to that possessed by the adjustable condenser of the Marconi patent * * * and was for the purpose of varying the periodicity of the primary circuit with which it was associated."

The Court below, therefore, *followed* the settled rule for determining the issue of infringement, as established in the cases cited by defendant in the footnotes on page 12 of its cross-petition, and in a host of other cases.

As to the cases cited by defendant in its third Reason for Granting the Writ (cross-petition, p. 13), the decision of the court below, on the measure of plaintiff's compensation, is not in conflict therewith but, rather, follows the principle, repeatedly set forth by this Court,[12] that a patentee is entitled to the benefit of all advantages which flow from his invention, whether or not such advantages are set forth in his patent and whether or not they were appreciated by the patentee.

CONCLUSION

It is therefore respectfully submitted that defendant's cross-petition for a writ of certiorari herein should be denied.

Respectfully submitted,

ABEL E. BLACKMAR, JR.,
RICHARD A. FORD,
Counsel for Cross-Respondent.

December, 1942.

Appendix

Rule 39 of the Court of Claims

In any patent suit it shall be competent for the parties to stipulate that the hearing in the first instance be limited to the issues of validity and infringement and when no such stipulation can be reached by the parties the court may order such procedure to be followed.

If the patent is held valid and infringed by the United States the court shall so adjudge and the case shall thereafter proceed according to law.

Extract from Rule 91 of the Court of Claims

Whenever either party desires to question the correctness or the sufficiency of the court's conclusions on its findings of fact or to amend the same, the complaining party shall file a motion which shall be known as a motion for a new trial. * * * Motions for new trial, except as provided by section 175 of the Judicial Code (U. S. Code, title 28, sec. 282), shall be filed within 60 days from the time the judgment of the court is announced.

SUPREME COURT OF THE UNITED STATES.

Nos. 369, 373.—October Term, 1942.

369	Marconi Wireless Telegraph Company of America, Petitioner, *vs.* The United States.	On Writs of Certiorari to the Court of Claims.
373	The United States, Petitioner, *vs.* Marconi Wireless Telegraph Company of America.	

[June 21, 1943.]

Mr. Chief Justice Stone delivered the opinion of the Court.

The Marconi Company brought this suit in the Court of Claims pursuant to 35 U. S. C. § 68, to recover damages for infringement of four United States patents. Two, No. 763,772, and reissue No. 11,913, were issued to Marconi, a third, No. 609,154, to Lodge, and a fourth, No. 803,684, to Fleming. The court held that the Marconi reissue patent was not infringed. It held also that the claims in suit, other than Claim 16, of the Marconi patent No. 763,772, are invalid; and that Claim 16 of the patent is valid and was infringed. It gave judgment for petitioner on this claim in the sum of $42,984.93 with interest. It held that the Lodge patent was valid and infringed, and that the Fleming patent was not infringed and was rendered void by an improper disclaimer. The case comes here on certiorari, 317 U. S. 620, 28 U. S. C. § 288(b), on petition of the Marconi Company in No. 369, to review the judgment of the Court of Claims holding invalid the claims in suit, other than Claim 16, of the Marconi patent, and holding the Fleming patent invalid and not infringed, and on petition of the Government in No. 373, to review the decision allowing recovery for infringement of Claim 16 of the Marconi patent. No review was sought by either party of so much of the court's judgment as sustained the Lodge patent and held the first Marconi reissue patent not infringed.

Marconi Patent No. 763,772.

This patent, granted June 28, 1904, on an application filed November 10, 1900, and assigned to the Marconi Company on March 6, 1905,[1] is for improvements in apparatus for wireless telegraphy by means of Hertzian oscillations or electrical waves. In wireless telegraphy, signals given by means of controlled electrical pulsations are transmitted through the ether by means of the so-called Hertzian or radio waves. Hertzian waves are electrical oscillations which travel with the speed of light and have varying wave lengths and consequent frequencies intermediate between the frequency ranges of light and sound waves. The transmitting apparatus used for sending the signals is capable, when actuated by a telegraph key or other signalling device, of producing, for short periods of variable lengths, electrical oscillations of radio frequency (over 10,000 cycles per second) in an antenna or open circuit from which the oscillations are radiated to a distant receiving apparatus. The receiver has an open antenna circuit which is electrically responsive to the transmitted waves and is capable of using those responses to actuate by means of a relay or amplifier any convenient form of signalling apparatus for making audible an electrically transmitted signal, such as a telegraph sounder or a loud speaker. In brief, signals at the transmitter are utilized to control high frequency electrical oscillations which are radiated by an antenna through the ether to the distant receiver and there produce an audible or visible signal.

All of these were familiar devices at the time of Marconi's application for the patent now in suit. By that time radio had passed from the theoretical to the practical and commercially successful. Four years before, Marconi had applied for his original and basic patent, which was granted as No. 586,193, July 13, 1897 and reissued June 4, 1904, as reissue No. 11,913. He applied for his corresponding British patent, No. 12039 of 1896, on June 2, 1896. Marconi's original patent showed a two-circuit system, in which the high-frequency oscillations originated in the transmitter antenna circuit and the detecting device was connected directly in the receiver antenna circuit. Between 1896 and 1900 he demonstrated on numerous occasions the practical success of

[1] On November 25, 1919, The Marconi Company assigned to the Radio Corporation of America all of its assets, including the patents here in suit, but reserved, and agreed to prosecute, the present claims against the United States, on which it had instituted suit on July 29, 1916.

his apparatus, attaining successful transmission at distances of 70 and 80 miles. During those years he applied for a large number of patents in this and other countries for improvements on his system of radio communication.[2]

The particular advance said to have been achieved by the Marconi patent with which we are here concerned was the use of two high frequency circuits in the transmitter and two in the receiver, all four so adjusted as to be resonant to the same frequency or multiples of it. The circuits are so constructed that the electrical impulses in the antenna circuit of the transmitter vibrate longer with the application to the transmitter of a given amount of electrical energy than had been the case in the previous structures known to the art, and the selectivity and sensitivity of the receiver is likewise enhanced. Thus increased efficiency in the transmission and reception of signals is obtained. The specifications of the Marconi patent state that its object is "to increase the efficiency of the system and to provide new and simple means whereby oscillations of electrical waves from a transmitting station may be localized when desired at any one selected receiving station or stations out of a group of several receiving-stations."

The specifications describe an arrangement of four high frequency circuits tuned to one another—two at the sending station associated with a source of low frequency oscillations, and two at the receiving station associated with a relay or amplifier operating a signalling device. At the sending station there is an open antenna circuit which is "a good radiator", connected with the secondary coil of a transformer, and through it inductively coupled with a closed circuit, which is connected with the primary coil of the transformer, this closed circuit being a "persistent oscillator." At the receiving station there is an open antenna circuit constituting a "good absorber" inductively coupled with a closed circuit capable of accumulating the received oscillations.

---

[2] See Marconi Wireless Tel. Co. *v.* National Electric Signalling Co., 213 Fed. 815, 825, 829-31; Encyclopedia Britannica (14th Ed.) vol. 14, p. 869; Dunlap, Marconi, The Man and His Wireless; Jacot and Collier, Marconi—Master of Space; Vyvyan, Wireless Over Thirty Years; Fleming, Electric Wave Telegraphy, 426-443.

Marconi was granted eight other United States patents for wireless apparatus on applications filed between the filing dates of Nos. 586,193 and 763,772. They are Nos. 624,516, 627,650, 647,007, 647,008, 647,009, 650,139, 650,140, 668,315.

The patent, in describing the arrangement of the apparatus so as to secure the desired resonance or tuning, specifies: "The capacity and self-induction of the four circuits—i. e., the primary and secondary circuits at the transmitting-station and the primary and secondary circuits at any one of the receiving-stations in a communicating system are each and all to be so independently adjusted as to make the product of the self-induction multiplied by the capacity the same in each case or multiples of each other—that is to say, the electrical time periods of the four circuits are to be the same or octaves of each other".[3] And again, "In employing this invention to localize the transmission of intelligence at one of several receiving-stations the time period of the circuits at each of the receiving-stations is so arranged as to be different from those of the other stations. If the time periods of the circuits of the transmitting-station are varied until they are in resonance with those of one of the receiving-stations, that one alone of all the receiving-stations will respond, provided that the distance between the transmitting and receiving stations is not too small".

The drawings and specifications show a closed circuit at the transmitting station connected with the primary of an induction coil, and embracing a source of electrical current and a circuit-closing key or other signalling device. The secondary of the induction coil is connected in a circuit which includes a spark gap or other producer of high frequency oscillations and, in a shunt around the spark gap, the primary coil of an oscillation transformer and a condenser, preferably so arranged that its capacity can readily be varied. This shunt circuit constitutes one of the two tuned circuits of the transmitter, and is often referred to as the closed or charging circuit. The secondary coil of the trans-

[3] Capacity is the property of an electrical circuit which enables it to receive and store an electrical charge when a voltage is applied to it, and to release that charge as the applied voltage is withdrawn, thereby causing a current to flow in the circuit. Although any conductor of electricity has capacity to some degree, that property is substantially enhanced in a circuit by the use of a condenser, consisting of two or more metal plates separated by a non-conductor, such that when a voltage is applied to the circuit one plate will become positively and the other negatively charged.

Self-inductance is the property of a circuit by which, when the amount or direction of the current passing through it is changed, the magnetic stresses created induce a voltage opposed to the change. Although any conductor has self-inductance to some degree, that property is most marked in a coil.

See generally Albert, Electrical Fundamentals of Communication, Chs. V, VI, VII, and IX; Terman, Radio Engineering, Chs. II and III; Morecroft, Principles of Radio Communication, Chs. I, II, III; Lauer and Brown, Radio Engineering Principles, Chs. I and II.

former is connected in the open or antenna circuit, one end of which is connected with the earth, the other to a vertical wire antenna or an elevated plate. This antenna circuit also includes an induction coil, preferably one whose inductance is readily variable, located between the antenna or plate and the transformer.

The receiver consists of a similar antenna circuit connected with the primary coil of a transformer, and having a variable induction coil located between the antenna or plate and the transformer. A shunt circuit bridging the transformer and containing a condenser which is preferably adjustable may also be added. The secondary coil of the transformer is connected through one or more interposed inductance coils, "preferably a variable inductance", with the terminals of a coherer[4] or other suitable detector of electrical oscillations. The closed receiver circuit also contained one or more condensers.

The devices and arrangements specified are suitable for effecting the electrical transmission of signals in the manner already indicated. By the maintenance of the same high frequency throughout the four circuit system the cumulative resonance is attained which gives the desired increased efficiency in transmission and increased selectivity at the receiving station.

The patent describes the operation of the four circuits as follows, beginning with the transmitter:

"In operation the signalling-key *b* is pressed, and this closes the primary of the induction-coil. Current then rushes through the transformer-circuit and the condenser *c* is charged, and subsequently discharges through the spark-gap. If the capacity, the inductance, and the resistance of the circuit are of suitable values, the discharge is oscillatory, with the result that alternating currents of high frequency pass through the primary of the transformer and induce similar oscillations in the secondary, these

[4] A coherer was a device disclosed by Branly as early as 1891. It was used by Lodge in experiments described in the London Electrician for June 15, 1894, p. 189, and was in common use thereafter as a detector of radio waves until replaced by the crystal and the cathode-anode tube. The most common form consisted of a tube containing metal filings which, in their normal state, were a non-conductor. When placed in a circuit through which high frequency oscillations passed, the filings aligned themselves in a continuous stream through which the low frequency electrical current operating a key or other signalling device could pass. By means of a device which tapped the sides of the tube, the stream of filings was broken when the high-frequency oscillations ceased. Thus the coherer was a sensitive device by which weak, high-frequency signals could be made to actuate a low frequency current of sufficient power to operate a telegraphic key or other device producing a visible or audible signal.

oscillations being rapidly radiated in the form of electric waves by the elevated conductor (antenna).

"For the best results and in order to effect the selection of the station or stations whereat the transmitted oscillations are to be received I include in the open secondary circuit of the transformer, and preferably between the radiator *f* and the secondary coil *d*', an inductance-coil *g*, Fig. 1, having numerous coils, and the connection is such that a greater or less number of turns of the coil can be put in use, the proper number being ascertained by experiment."

The invention thus described may summarily be stated to be a structure and arrangement of four high frequency circuits, with means of independently adjusting each so that all four may be brought into electrical resonance with one another. This is the broad invention covered by Claim 20. Combinations covering so much of the invention as is embodied in the transmitter and the receiver respectively are separately claimed.[3]

Long before Marconi's application for this patent the scientific principles of which he made use were well understood and the particular appliances constituting elements in the apparatus combination which he claimed were well known. About seventy years ago Clerk Maxwell described the scientific theory of wireless communication through the transmission of electrical energy by other waves.[4] Between 1878 and 1890 Hertz devised apparatus for achieving that result which was described by de Tunzelmann in a series of articles published in the London Electrician in 1888. One, of September 21, 1888, showed a transmitter comprising a closed circuit inductively coupled with an open circuit. The closed circuit included a switch or circuit breaker capable of use for send-

[3] Of the claims in suit in No. 369, Claims 19 and 20 cover the four circuit system, while Claims 1, 3, 6, 8, 11 and 12 cover the two transmitter circuits and Claims 2, 13, 14, 17, 18 and 19 cover the two receiver circuits. Claim 10 merely provides that the four circuits be in resonance with each other and hence does not prescribe means of adjusting the tuning. Claim 11 likewise prescribes no means of adjustment. The other claims provide means of adjustment, either a "variable inductance" (Claims 1, 2, 3, 8, 12, 13, 18, and 19) or more generally "means" for adjusting the period of the circuits (Claims 3, 6, 14 and 17). Some of the claims merely provide means of adjusting the tuning of the antenna circuit (Claims 1, 2, 8, 12, and 13) and hence do not require that the closed circuits be tuned. Others either specifically prescribe the adjustable tuning of both circuits at transmitter (Claims 3, 6, or receiver (Claims 18 and 19, or both (Claim 20), or else prescribe means for adjusting the two transformer circuits to electrical resonance with each other, substantially as described (Claims 14 and 17).

[4] Maxwell, Theory of the Electromagnetic Field, 1865, Philosophical Transactions of the Royal Society (1864), 459; 1 Scientific Papers of James Clerk Maxwell, 526.

ing signals, and an automatic circuit breaker capable, when the switch was closed, of setting up an intermittent current in the closed circuit which in turn induced through a transformer an intermittent current of higher voltage in the open circuit. The open circuit included a spark gap across which a succession of sparks were caused to leap whenever the signal switch was closed, each spark producing a series of high frequency oscillations in the open circuit.

By connecting the spark gap to large area plates in the open circuit Hertz increased the capacity and thus not only increased the force of the sparks but also changed one of the two factors determining the frequency of the oscillations in the circuit, and hence the wave length of the oscillations transmitted. Hertz's receiver was shown as a rectangle of wire connected to the knobs of a spark gap, both the wire and the spark gap being of specified lengths of such relationship as to render the circuit resonant to the wave lengths in the transmitter. At times Hertz attached to the rectangle additional vertical wires which provided additional capacity, and whose length could readily be varied so as to vary the wave lengths to which the receiver was responsive, thus providing a "method of adjusting the capacity" of the receiver.[7] Thus Hertz at the outset of radio communication recognized the importance of resonance and provided means for securing it by tuning both his transmitting and receiving circuits to the same frequency, by adjusting the capacity of each.[8]

Lodge, writing in the London Electrician in 1894, elaborated further on the discoveries of Hertz and on his own experiments along the same lines. In one article, of June 8, 1894, he discussed phenomena of resonance and made an observation which underlies several of the disclosures in Marconi's patent. Lodge pointed out that some circuits were by their nature persistent vibrators, i. e.,

---

7 See The London Electrician for September 21, 1888, p. 628.

Ebert, in The London Electrician for July 6, 1894, p. 333, likewise pointed out that Hertz's receivers are "so arranged that they show the maximum resonant effect with a given exciter; they are 'electrically tuned'".

8 De Tunzelmann shows that Hertz clearly understood the principles of electrical resonance. Some of his early experiments were designed to determine whether principles of resonance were applicable to high frequency electrical circuits. From them Hertz concluded that "an oscillatory current of definite period would, other conditions being the same, exert a much greater inductive effect upon one of equal period than upon one differing even slightly from it". *Id.* p. 626. Hertz knew that the frequency to which a circuit was resonant was a function of the square root of the product of the self inductance and capacity in the circuit and by [redacted] a formula similar to that now used he calculated the approximate frequency of the oscillations produced by his transmitter. *Id.*, September 28, 1888, 664 5.

were able to sustain for a long period oscillations set up in them, while others were so constructed that their oscillations were rapidly damped. He said that a receiver so constructed as to be rapidly damped would respond to waves of almost any frequency, while one that was a persistent vibrator would respond only to waves of its own natural periodicity. Lodge pointed out further that Hertz' transmitter "radiates very powerfully" but that "In consequence of its radiation of energy, its vibrations are rapidly damped, and it only gives some three or four good strong swings. Hence it follows that it has a wide range of excitation, *i. e.*, it can excite sparks in conductors barely at all in tune with it." On the other hand Hertz' receiver was "not a good absorber but a persistent vibrator, well adapted for picking up disturbances of precise and measurable wave-length." Lodge concluded that "The two conditions, conspicuous energy of radiation and persistent vibration electrically produced, are at present incompatible." (pp. 154-5).

In 1892, Crookes published an article in the Fortnightly Review in which he definitely suggested the use of Hertzian waves for wireless telegraphy and pointed out that the method of achieving that result was to be found in the use and improvement of then known means of generating electrical waves of any desired wave length, to be transmitted through the ether to a receiver, both sending and receiving instruments being attuned to a definite wave length.[9] A year later Tesla, who was then preoccupied with the wireless transmission of power for use in lighting or for the operation of dynamos, proposed, in a lecture before the Franklin Institute in Philadelphia, the use of adjustable high frequency oscillations for wireless transmission of signals.[10]

Marconi's original patent No. 586,193, which was granted July 13, 1897, and became reissue No. 11,913, disclosed a two-circuit system for the transmission and reception of Hertzian waves. The transmitter comprised an antenna circuit connected at one end to an aerial plate and at the other to the ground, and containing a spark gap. To the knobs of the spark gap was connected a transformer whose secondary was connected with a source of current and a signalling key. The low frequency current thereby induced in the antenna circuit was caused to discharge through the spark gap, producing the high frequency oscillations which

[9] Fortnightly Review, No. 101, February, 1892, 173, 174-5.

[10] Martin, Inventions, Researches and Writings of Nikola Tesla, pp. 346-8.

were radiated by the antenna. The receiver similarly contained an antenna circuit between an elevated plate and the ground, in which a coherer was directly connected. Marconi claimed the construction of transmitter and receiver so as to be resonant to the same frequency, and described means of doing so by careful determination of the size of the aerial plates.

The Tesla patent No. 645,576, applied for September 2, 1897 and allowed March 20, 1900, disclosed a four-circuit system, having two circuits each at transmitter and receiver, and recommended that all four circuits be tuned to the same frequency. Tesla's apparatus was devised primarily for the transmission of energy to any form of energy-consuming device by using the rarified atmosphere at high elevations as a conductor when subjected to the electrical pressure of a very high voltage. But he also recognized that his apparatus could, without change, be used for wireless communication, which is dependent upon the transmission of electrical energy. His specifications declare: "The apparatus which I have shown will obviously have many other valuable uses—as, for instance, when it is desired to transmit intelligible messages to great distances . . ."[11]

Tesla's specifications disclosed an arrangement of four circuits, an open antenna circuit coupled, through a transformer, to a closed charging circuit at the transmitter, and an open antenna circuit at the receiver similarly coupled to a closed detector circuit. His patent also instructed those skilled in the art that the open and closed circuits in the transmitting system and in the receiving system should be in electrical resonance with each other. His specifications state that the "primary and secondary circuits in the trans-

[11] Tesla's specifications state that the current should preferably be "of very considerable frequency". In describing apparatus used experimentally by him, the specifications state that the oscillations are generated in the charging circuit by the periodic discharge of a condenser by means of "a mechanically operated break", a means whose effects are similar to those of the spark gap generally used at this period in the radio art. He further states that the inductance of the charging circuit is so calculated that the "primary circuit vibrates generally according to adjustment, from two hundred and thirty thousand to two hundred and fifty thousand times per second". The range of radio frequencies in use in 1917 was said by a witness for the plaintiff to extend from 30,000 to 1,500,000 cycles per second. The range of frequencies allocated for radio use by the International Telecommunication Convention, proclaimed June 27, 1934, 49 Stat. 2391, 2459, is from 10 to 60,000 kilocycles (10,000 to 60,000,000 cycles) per second, and the spectrum of waves over which the Federal Communications Commission currently exercises jurisdiction extends from 10 to 500,000 kilocycles. Code of Federal Regulations, Title 47, Ch. I, § 2.71. Thus Tesla's apparatus was intended to operate at radio frequencies.

mitting apparatus" are "carefully synchronized." They describe the method of achieving this by adjusting the length of wire in the secondary winding of the oscillation transformer in the transmitter, and similarly in the receiver, so that "the points of highest potential are made to coincide with the elevated terminals" of the antenna, i. e., so that the antenna circuit will be resonant to the frequency developed in the charging circuit of the transmitter. The specifications further state that "the results were particularly satisfactory when the primary coil or system A' and its secondary C" [of the receiver] was carefully adjusted so as to vibrate in synchronism with the transmitting coil or system AC."

Tesla thus anticipated the following features of the Marconi patent: A charging circuit in the transmitter for causing oscillations of the desired frequency, coupled, through a transformer, with the open antenna circuit, and the synchronization of the two circuits by the proper disposition of the inductance in either the closed or the antenna circuit or both. By this and the added disclosure of the two-circuit arrangement in the receiver with similar adjustment, he anticipated the four circuit tuned combination of Marconi. A feature of the Marconi combination not shown by Tesla was the use of a variable inductance as a means of adjusting the tuning the antenna circuit of transmitter and receiver. This was developed by Lodge after Tesla's patent out before the Marconi patent in suit

In patent No. 609,154, applied for February 1, 1898 and allowed August 16, 1898, before Marconi's application, Lodge disclosed an adjustable induction coil in the open or antenna circuit in a wireless transmitter or receiver or both to enable transmitter and receiver to be tuned together. His patent provided for the use, in the open circuits of a transmitter and a receiver of Hertzian waves, of a self-induction coil between a pair of capacity areas which he stated might be antenna and earth. His specifications state that a coil located as described could be made adjustable at will so as to vary the value of its self-inductance; that the adjustment, to secure the "desired frequency of vibration or syntony with a particular distant station", may be attained either "by replacing one coil by another" or by the use of a coil constructed with a movable switch so related to the coil as to short circuit, when closed, any desired number of turns of the wire, "so that the whole or any smaller portion of the inductance available may be used in accordance with the correspondingly-

attuned receiver at the particular station to which it is desired to signal". Thus Lodge adjusted his tuning by varying the self-inductance of the antenna circuits, for, as he explained, the adjustment of wave lengths, and hence of frequency in the circuits, could be made by varying either or both the inductance and capacity, which are the factors controlling wave length and hence frequency in the antenna circuits.

Lodge thus broadly claimed the tuning, by means of a variable inductance, of the antenna circuits in a system of radio communication. His specifications disclose what is substantially a two-circuit system, with one high frequency circuit at the transmitter and one at the receiver. He also showed a two-circuit receiver with a tuned antenna circuit, his detector circuit at the receiver being connected with the terminals of a secondary coil wound around the variable inductance coil in the antenna circuit and thus inductively coupled through a transformer with the antenna circuit.[12] Lodge thus supplied the means of varying inductance and hence tuning which was lacking in the Tesla patent. He also showed a receiver which completely anticipated those of the Marconi receiver claims which prescribe adjustable means of tuning only in the antenna circuit (Claims 2, 13 and 18) and partially anticipated the other receiver claims.

The Stone patent No. 714,756, applied for February 8, 1900, nine months before Marconi's application, and allowed ~~February~~ December 2, 1902, a year and a half before the grant of Marconi's patent, showed a four circuit wireless telegraph apparatus substantially like that later specified and patented by Marconi. It described adjustable tuning, by means of a variable inductance, of the closed circuits of both transmitter and receiver. It also recommended that the two antenna circuits be so constructed as to be resonant to the same frequencies as the closed circuits. This recommendation was added by amendment to the specifications made after Marconi had filed his application, and the principal question is whether the amendments were in point of substance a departure from Stone's invention as disclosed by his application.

---

12 Marconi's patent No. 627,650, of June 27, 1899, similarly showed a two-circuit receiving system, in which the coherer was placed in a closed circuit which was inductively coupled with a tuned antenna circuit. The Court of Claims found, however, that this patent did not clearly disclose the desirability of tuning both circuits.

Stone's application shows an intimate understanding of the mathematical and physical principles underlying radio communication and electrical circuits in general. It contains a critical analysis of the state of the art of radio transmission and reception. He said that as yet it had not been found possible so to tune stations using a vertical antenna as to make possible selective reception by a particular station to the exclusion of others. His effort, accordingly, was to transmit a "simple harmonic wave" of well defined periodicity to a receiver which would be selectively responsive to the particular frequency transmitted, and thereby to achieve greater precision of tuning and a higher degree of selectivity.

Stone discusses in some detail the difference between "natural" and "forced" oscillations. He says "If the electrical equilibrium of a conductor be abruptly disturbed and the conductor thereafter be left to itself, electric currents will flow in the conductor which tend to ultimately restore the condition of electrical equilibrium". He points out that a closed circuit containing a condenser and a coil is "capable of oscillatory restoration of equilibrium upon the sudden discharge of the condenser" and that "the electrical oscillations which it supports when its equilibrium is abruptly disturbed and it is then left to itself are known as the *natural vibrations* or oscillations of the system."

In addition to its ability to originate "natural vibrations" when its electrical equilibrium is disturbed, Stone says that an electrical circuit is also "capable of supporting what are termed *forced vibrations*" when electrical oscillations elsewhere created are impressed upon it. In contrast to the "natural" vibrations of a circuit, whose frequency depends upon "the relation between the electro-magnetic constants [capacity and self-inductance] of the circuit", the frequency of the "forced" vibrations is "independent of the constants of the circuit" on which they are impressed and "depends only upon the period [frequency] of the impressed force." In other words, Stone found that it was possible not only to originate high-frequency oscillations in a circuit, and to determine their frequency by proper distribution of capacity and self-inductance in the circuit, but also to transfer those oscillations to another circuit and retain their original frequency.

Stone points out that in the existing systems of radio transmission the electric oscillations are "naturally" developed in the

antenna circuit by the sudden discharge of accumulated electrical force through a spark gap in that circuit. Such oscillations are "necessarily of a complex character and consist of a great variety of superimposed simple vibrations of different frequencies". "Similarly the vertical conductor at the receiving station is capable of receiving and responding to vibrations of a great variety of frequencies so that the electro-magnetic waves which emanate from one vertical conductor used as a transmitter are capable of exciting vibrations in any other vertical wire as a receiver . . . and the messages from the transmitting station will not be selectively received by the particular receiving station with which it is desireus to communicate, and will interfere with the operation of other receiving stations within its sphere of influence."

In contrast to the two circuit system whose inadequacies he had thus described, Stone's drawings and specifications disclose a four circuit system for transmitting and receiving radio waves which was very similar to that later disclosed by Marconi. The transmitter included a source of low frequency oscillating current and a telegraph or signalling key connected in a circuit which was inductively coupled with another closed circuit. This included an induction coil, a condenser, and a spark gap capable of generating high frequency oscillations. It in turn was inductively coupled through a transformer with an open antenna circuit connected to an aerial capacity at one end and the earth at the other. The receiver included a similar antenna circuit, inductively coupled with a closed oscillating circuit containing an induction coil, a condenser, and a coherer or other detector of radio waves.

Stone thus recognized, although he used different terminology, the fact, previously observed by Lodge, that an open antenna circuit, so constructed as to be an efficient radiator, was not an oscillator capable of producing natural waves of a single well-defined periodicity, and consequently had a wide range of excitation. He adopted the same remedy for this defect as Marconi later did, namely to produce the oscillations in a closed circuit capable of generating persistent vibrations of well-defined periodicity, and then induce those oscillations in an open antenna circuit capable of radiating them efficiently to a distant resonant receiver. He states that the vibrations in his closed circuit "begin with a maximum of amplitude and gradually die away", a good description of

the results obtainable by a "persistent oscillator."[13] Similarly in his receiver Stone recognized that an open antenna circuit (Lodge's "good absorber") was not a highly sensitive responder to waves of a particular frequency, and accordingly he sought to augment the selectivity of tuning at the receiver by interposing between the antenna circuit and the responding device a closed circuit which would be a more persistent vibrator and hence render the receiving apparatus more selectively responsive to waves of a particular frequency. In so doing, however, as will presently appear, he did not disregard the favorable effect on selectivity of tuning afforded by making the antenna circuits resonant to the transmitted frequency.

Stone's application recommends that the inductance coils in the closed circuits at transmitter and receiver "be made adjustable and serve as a means whereby the operators may adjust the apparatus to the particular frequency which it is intended to employ". He thus disclosed a means of adjusting the tuning of the closed circuits by variable inductance. His original application nowhere states in so many words that the antenna circuits should be tuned, nor do its specifications or drawings explicitly disclose any means for adjusting the tuning of those circuits. But there is nothing in them to suggest that Stone did not intend to have the antenna circuits tuned, and we think that the principles which he recognized in his application, the purpose which he sought to achieve, and certain passages in his specifications, show that he recognized, as they plainly suggest to those skilled in the art, the desirability of tuning the antenna circuits as well. The disclosures

[13] That the closed circuit was intended to be a "persistent oscillator" is also brought out by Stone's emphasis on "loose coupling." Stone's application explained in detail the fact that when two circuits are inductively coupled together there normally result "two degrees of freedom", that is to say, the superposition of two frequencies in the same circuit because of the effect on each of the magnetic lines of force set up by the other. He discussed in detail methods of eliminating this superposition, which interfered with accurate selectivity of tuning, by so constructing his circuits as to be "loosely coupled." This he achieved by including in the closed circuits a large inductance coil, which had the effect of "swamping" the undesirable effect of the lines of force set up in the primary of the transformer by the current induced in the secondary. Since the turns of wire in the primary of the transformer constituted a relatively small part of the total inductance in the closed circuit the effect of those turns on the frequency of the circuit was minimized.

But the testimony at the trial was in substantial agreement that the looser the coupling the slower is the transfer of energy from the closed charging circuit to the open antenna circuit. Hence the use of loose coupling presupposes a charging circuit that will store its energy for a considerable period, i. e., that will maintain persistent oscillations.

of his application were thus an adequate basis for the specific recommendation, later added by amendment, as to the desirability of constructing the antenna circuits so as to be resonant to the frequency produced in the charging circuit of the transmitter.

The major purpose of Stone's system was the achievement of greater selectivity of tuning. His objective was to transmit waves "of but a single frequency" and to receive them at a station which "shall be operated only by electric waves of a single frequency and no others". He states:

"By my invention the vertical conductor of the transmitting station is made the source of electro-magnetic waves of but a single periodicity, and the translating apparatus at the receiving station is caused to be selectively responsive to waves of but a single periodicity so that the transmitting apparatus corresponds to a tuning fork sending but a single simple musical tone, and the receiving apparatus corresponds to an acoustic resonator capable of absorbing the energy of that single, simple musical tone only."

He says that "when the apparatus at a particular [receiving] station" is properly tuned to a particular transmitting station the receiver will selectively receive messages from it. He adds:

"Moreover by my invention the operator at the transmitting or receiving station may at will adjust the apparatus at his command in such a way as to place himself in communication with any one of a number of stations . . . by bringing his apparatus into resonance with the periodicity employed."

And with respect to the transmitter he says, "It is to be understood that any suitable device may be employed to develop the simple harmonic force impressed upon the vertical wire [antenna]. It is sufficient to develop in the vertical wire practically simple harmonic vibrations of a fixed and high frequency."

These statements sufficiently indicate Stone's broad purpose of providing a high degree of tuning at sending and receiving stations. In seeking to achieve that end he not unnaturally placed emphasis on the tuning of the closed circuits, the association of which with the antenna circuits was an important improvement which he was the first to make. But he also made it plain that it was the sending and receiving "apparatus" which he wished to tune, so that the sending "apparatus" "would correspond to a tuning fork" and the receiving "apparatus" to "an acoustic resonator capable of absorbing the energy of that single simple musical tone". And this he sought to achieve by "any suitable device".

Stone thus emphasized the desirability of making the entire transmitting and receiving "apparatus" resonant to a particular frequency. As none of the circuits are resonant to a desired frequency unless they are tuned to that frequency, this reference to the transmitting and receiving apparatus as being brought into resonance with each other cannot fairly be said to mean that only some of the circuits at the transmitter and receiver were to be tuned. To say that by this reference to the tuning of sending and receiving apparatus he meant to confine his invention to the tuning of some only of the circuits in that apparatus is to read into his specifications a restriction which is plainly not there and which contradicts everything they say about the desirability of resonance of the apparatus. It is to read the specifications, which taken in their entirety are merely descriptive or illustrative of his invention, compare *Continental Paper Bag Co.* v. *Eastern Paper Bag Co.*, 210 U. S. 405, 418, 419-20, as though they were claims whose function is to exclude from the patent all that is not specifically claimed. *Mahn* v. *Harwood*, 112 U. S. 354, 361; *McClain* v. *Ortmayer*, 141 U. S. 419, 423-5; *Milcor Steel Co.* v. *Fuller*, 316 U. S. 143, 146.

Stone had pointed out that the tuning of the antenna circuits shown in the prior art did not of itself afford sufficient selectivity. It was for that reason that he used the tuned closed circuit in association with the antenna circuit. But in the face of his emphasis on the desirability of tuning the transmitting and receiving apparatus, we cannot impute to him an intention to exclude from his apparatus the well known use of tuning in the antenna circuits as an aid to the selectivity which it was his purpose to achieve. The inference to be drawn is rather that he intended the tuned closed circuits which he proposed to add to the then known systems of radio communication, to be used in association with any existing type of vertical wire antenna circuit, including one so constructed as to be either resonant to a particular frequency, or adjustably resonant to any desired frequency, both of which involved tuning.

Stone's full appreciation of the value of making all of his circuits resonant to the same frequency is shown by his suggestion to insert, between the closed and antenna circuits at the transmitter and receiver, one or more additional closed circuits, so constructed as to be highly resonant to the particular frequency

employed. He says that the purpose of such an intermediate circuit is "to weed out and thereby screen" the antenna circuit at the transmitter and the detecting device at the receiver from any harmonics or other impurities in the wave structure.

He states: "This screening action of an interposed resonant circuit is due to the well known property of such circuits by which a resonant circuit favors the development in it of simple harmonic currents of the period to which it is attuned and strongly opposes the development in it of simple harmonic currents of other periodicities". His original application thus disclosed the advantage, where vibrations created in one circuit are to be impressed on another, of making the latter circuit resonant to the same frequency as the former, in view of the "well known property" of a resonant circuit to favor the "development" in it of forced vibrations of the same frequency as its natural periodicity.[14]

Stone's application shows that these principles of resonant circuits were no less applicable to the antenna circuit, and suggests the use of "any suitable device" to "develop" in the antenna circuit the "simple harmonic force impressed" upon it. It was then well known in the art that every electrical circuit is to some degree resonant to a particular frequency to which it responds more readily and powerfully than to others. Although the degree of resonance attained by a vertical wire is small, its natural resonance is no different in kind from that of a closed circuit such as Stone's screening circuit. Stone recognized this in his application. In describing the complex natural vibrations set up by a sudden discharge in an antenna circuit, such as that commonly used at the time of his application, Stone said that "the vibrations consist of a simple harmonic vibration of lower period than all the others, known as the fundamental with a great variety of superimposed simple harmonics of higher periodicity superimposed thereon." And he says that the oscillations developed in the charging circuit of his system "induce corresponding oscillations in the vertical wire", which are "virtually" forced vibrations, and "practically independent, as regards their frequency, of the constants of the second circuit in which they are induced"—a plain recognition

[14] Stone's recognition of the similarity between his antenna circuit and his screening circuit is further shown by his direction that the coupling between the screening circuit and the charging circuit, like that between the antenna and charging circuits where no screening circuit is used, be loose. See note 12, supra.

that the antenna circuit has electro-magnetic constants which affect its natural periodicity, and that that natural periodicity does have some effect on the frequency of the vibrations impressed upon the antenna circuit.[19]

Thus Stone did not, as the Marconi Company suggests, say that the antenna circuit had no natural periodicity. He recognized that its natural periodicity was less strongly marked than that of his closed circuit, and hence that the wave structure could be greatly improved by creating the oscillations in a closed circuit such as he described. But he also plainly recognized that the antenna circuit, like his screening circuit, was a circuit having a natural period of vibration which would therefore be more responsive to impressed oscillations of that same periodicity. Since he had previously said that "any suitable device may be employed to develop the simple harmonic force impressed upon the vertical wire", we think that Stone's specifications plainly suggested to those skilled in the art that they avail themselves of this means of developing in the antenna this simple harmonic force, and that they tune the antenna circuit in order to improve the strength and quality of the "forced" vibrations impressed upon it.

The Marconi Company argues that Stone's theory of "forced" oscillations presupposes that the open transmitter circuit be untuned. It is true that Stone said that such "forced" oscillations have a period of vibration which is "independent of the electrical constants of the circuit" on which they are impressed. But the fact that the "forced" vibration will retain its natural period whatever the frequency of the antenna circuit may be, does not preclude, as Stone showed, the tuning of that circuit so as to achieve maximum responsiveness to the vibrations impressed upon it. Stone's specifications indicate that he used the term "forced" merely as meaning that the vibrations are developed in another circuit and then transferred to the antenna by inductive coupling, as distinguished from "natural" vibrations which originate in the antenna or radiating circuit—in short that "forced" is merely used as a synonym for "induced". Thus he states is describing the operation of his transmitter, "The high frequency current . . . passing through the primary I, [of the antenna transformer] induces a corresponding high frequency electromotive

force and current in the secondary I_2 and forced electric vibrations result in the vertical conductor r . . . ."[15]

Hence there is ample support for the finding of the court below that

"By free oscillations is meant that their frequency was determined by the constants of the circuit in which they were generated. The Stone application as filed impressed these oscillations upon the open circuit, and therefore used 'forced' oscillations in the open circuit of the transmitter, that is, the frequency of the oscillations in the open circuit was determined by the frequency of the oscillations in the closed circuit.

"The effect of forcing vibrations upon a tuned and untuned circuit may be likened unto the effect of a tuning fork upon a stretched cord in a viscous medium. When the cord is vibrated by the tuning fork it has the same period as does the fork regardless of the natural period of the cord, but when the fork vibrations are in tune with the natural period or fundamental of the cord, then the amplitude of vibrations in the cord is a maximum".

Thus Stone's application, prior to Marconi, showed a four-circuit system, in which the oscillations were produced in a closed charging circuit and impressed on an open antenna circuit in the transmitter, and were similarly received in an open antenna circuit and by it induced in a closed circuit containing a detector. He showed the effect of resonance on the circuits resulting from their tuning to a desired frequency, and emphasized the importance of making the transmitting and receiving apparatus resonant to that frequency.

Stone's patent,[16] granted a year and a half before Marconi—although after Marconi's application was filed—makes explicit, as the patent law permits, what was implicit in Stone's application. By amendments to his specifications made April 8, 1902, he recom-

whether such period be that of

[15] Stone's language here makes it plain that throughout his allusions to a frequency developed in one circuit as being "impressed" or "forced" on another circuit when the two circuits are coupled through a transformer, are used figuratively or metaphorically only as synonymous with "induced". Scientifically the oscillations in the charging circuit are not impressed or forced on the other. The stress in the magnetic field of the first circuit sets up or induces corresponding stresses in the magnetic field of the other circuit. The resulting frequency in the second circuit is affected both by the frequency of the oscillations in the charging circuit and the inductance and capacity in the second circuit. The result may be the superposition of two frequencies in the second circuit. This may be avoided and a single frequency developed, as Stone showed, by tuning the second circuit so as to be resonant to the frequencies created in the first.

[16] At the insistence of the Patent Office Stone divided his original application, and was granted two patents, No. 714,756 for a method and No. 714,831 for apparatus. The former is the one particularly relied on here.

mended that the frequency impressed upon the vertical conductor at the transmitter "may or may not be the same as the natural period or fundamental of such conductor" and that the antenna circuit at the transmitter "may with advantage be so constructed as to be highly resonant to a particular frequency and the harmonic vibrations impressed thereon may well be of that frequency". Since Stone used a variable inductance to alter at will the frequency of the charging circuit, this direction plainly indicated that the frequency of the antenna circuit might also be variable, and suggested the inclusion of the well-known Lodge variable inductance in the construction of the antenna circuit to achieve that result. And since Stone had specified that "by my invention" the operator at the receiving station is able to "adjust" the receiving apparatus so as to place it in resonance with any particular transmitting station, his patent equally plainly suggested the use of the Lodge variable inductance as a means of adjusting the tuning of the receiving antenna.

Stone's 1902 amendments also suggested that "an elevated conductor that is aperiodic may be employed"—i. e., one having very weak natural periodicity and consequently "adapted to receive or transmit all frequencies". But this suggestion was accompanied by the alternative recommendation in the 1902 amendments that the antenna circuits at transmitter and receiver "may with advantage be made resonant to a particular frequency," i. e., be periodic. No inference can be drawn from this that only an aperiodic antenna was contemplated either by the application or the amendments. The application was sufficiently broad to cover both types, since both were suitable means of achieving under different conditions the results which the application described and sought to attain. The amendments thus merely clarified and explained in fuller detail two alternative means which could be employed in the invention described in the original application, one of those means being the construction of the antenna so as to be highly resonant, i. e., tuned, to a particular frequency.[17]

[17] This is borne out by the subsequent letter from Stone to the Commissioner of Patents dated June 7, 1902. Stone there refers to a letter by the Patent Office saying that the statement that a simple harmonic wave developed in the closed circuit "can be transferred to the elevated conductor and from the latter to the earth without change of form" is "an argument which the Office has no means of testing". Stone replied with arguments to show that the vibrations radiated by the antenna circuit would be sufficiently

The only respects in which it is seriously contended that Marconi desclosed invention over Stone are that Marconi explicitly claimed four circuit tuning before Stone had made it explicit by his 1902 amendment, and that Marconi disclosed means of adjusting the tuning of each of his four circuits whereas Stone had explicitly shown adjustable tuning only in the two closed circuits. But we think that neither Marconi's tuning of the two antenna circuits nor his use of the Lodge variable inductance to that end involved any invention over Stone. Two questions are involved, first, whether there was any invention over Stone in tuning the antenna circuits, and, second, whether there was any invention in the use of the Lodge variable inductance or any other known means of adjustment in order to make the tuning of the antenna circuits adjustable.

For reasons already indicated we think it clear that Stone showed tuning of the antenna circuits before Marconi, and if this involved invention Stone was the first inventor. Stone's application emphasized the desirability of tuning, and disclosed means of adjusting the tuning of the closed circuits His very explicit recognition of the increased selectivity attained by inductive coupling of several resonant circuits plainly suggested to those skilled in the art that the antenna circuit could with advantage be a resonant circuit, that is to say a tuned circuit, and hence that it was one of the circuits to be tuned. He stressed the importance of tuning "by any suitable device" the "apparatus" at transmitter and receiver, which included at both an antenna circuit.

Tuning of the antenna circuit was nothing new; Lodge had not only taught that the antenna circuits at transmitter and receiver should be tuned to each other but had shown a means of adjusting the tuning which was the precise means adopted by Marconi, and which Stone had, prior to Marconi, used to tune his closed circuit—the variable inductance. Tesla, too, had shown the tuning of the antenna circuit at the transmitter to the frequency developed by the charging circuit, and the tuning of both circuits at the re-

pure for practical purposes either if the antenna circuit were aperiodic, or if it had a fundamental which was of the same frequency as that of the forced vibrations impressed upon it, although they would not be pure if the antenna circuit had a marked natural periodicity and was untuned. This letter, while somewhat later in date than the amendments, reinforces the conclusion that the purpose of those amendments was to explain more fully the details of theory and practice necessary to the success of the idea underlying Stone's original invention.

ceiver to the frequency thus transmitted. Thus Marconi's improvement in tuning the antenna circuits is one of the principles which were well understood and stated by Stone himself before Marconi, and the mechanism for achieving which had previously been disclosed by Lodge and Stone.[18]

Since no invention over Stone was involved in tuning the antenna circuits, neither Marconi nor Stone made an invention by providing adjustable tuning of any of the circuits or by employing Lodge's variable inductance as a means of adjusting the tuning of the resonant four circuit arrangement earlier disclosed by Stone's application and patented by him. No invention was involved in employing the Lodge variable inductance for tuning either the closed or the open circuits in lieu of other structural modes of adjustment for that purpose. The variable inductance imparted no new function to the circuit; and merely making a known element of a known combination adjustable by a means of adjustment known to the art, when no new or unexpected result is obtained is not invention. *Peters* v. *Hanson*, 129 U. S. 541, 550-51, 553; *Electric Cable Co.* v. *Edison Co.*, 292 U. S. 69, 79, 80, and cases cited; *Smyth* v. *Sheridan*, 149 Fed. 208, 211; cf. *Bassick Co.* v. *Hollingshead Co.*, 298 U. S. 415, 424-5 and cases cited.

Stone's conception of his invention as disclosed by his patent antedated his application. It is carried back to June 30, ~~1899~~ 1899, seven months before his application, when, in a letter to Baker, he described in text and drawings his four circuit system for wireless telegraphy in substantially the same form as that disclosed by the application. His letter is explicit in recommending the tuning of the antenna circuits. In part he wrote as follows:

"Instead of utilizing the vertical wire [antenna] itself at the transmitting station as the oscillator, I propose to impress upon this vertical wire, oscillations from an oscillator, which oscilla-

[18] It is not without significance that Marconi's application was at one time rejected by the Patent Office because anticipated by Stone, and was ultimately allowed, on renewal of his application, on the sole ground that Marconi showed the use of a variable inductance as a means of tuning the antenna circuits, whereas Stone, in the opinion of the Examiner, tuned his antenna circuits by adjusting the length of the aerial conductor. All of Marconi's claims which included that element were allowed, and the Examiner stated that the remaining claims would be allowed if amended to include a variable inductance. Apparently through oversight, Claims 10 and 11, which failed to include that element, were included in the patent as granted. In allowing these claims the Examiner made no reference to Lodge's prior disclosure of a variable inductance in the antenna circuit.

tions shall be of a frequency corresponding to the fundamental of the wire. Similarly at the receiving station, I shall draw from the vertical wire, only that component of the complex wave which is of lowest frequency.

"If now the fundamental of the wire at the receiving station be the same as that of the wire at the transmitting station, then the receiving station may receive signals from the transmitting station, but if it be different from that of the transmitting station, it may not receive those signals.

. . . . . .

"The tuning of these circuits one to another and all to the same frequency will probably be best accomplished empirically, though the best general proportions may be determined mathematically."

On July 18, 1899, Stone again wrote to Baker, mathematically demonstrating how to achieve the single frequency by means of forced vibrations. He expressed as a trigonometric function the form taken by the forced wave "if the period of the impressed force be the same as that of the fundamental of the vertical wire." He also pointed out that the transmitting circuit which he had disclosed in his earlier letter to Baker, "is practically the same as that employed by Tesla", except that Stone added an inductance coil in the closed circuit "to give additional means of tuning" and to "swamp" the reactions from the coil of the oscillation transformer and thus loosen the coupling between the open and closed circuit of the transmitter.[19] His recognition of the effect upon the current in the antenna if it is of the same period as the charging circuit; his statement that his transmitting system was the same as that employed by Tesla; his recognition that the fundamental of the receiver should be the same as that of the transmitter antenna when used for the transmission of a single frequency, and finally his statement that all four circuits are to be tuned, "one to another and all to the same frequency," all indicate his understanding of the principles of resonance and of the significance of tuning the antenna circuits.

Stone disclosed his invention to others, and in January, 1900, described it to his class at the Massachusetts Institute of Technology. Before 1900 he was diligent in obtaining capital to promote his invention. Early in 1901 a syndicate was organized to finance laboratory experiments. The Stone Telegraph & Telephone Co. was organized in December, 1901. It constructed sev-

[19] See footnote 13, *supra*.

eral experimental stations in 1902 and 1903; beginning in 1904 or 1905 it built wireless stations and sold apparatus, equipped a Navy collier and some battleships, and it applied for a large number of patents. The apparatus used in the stations is described by Stone's testimony in this suit as having resonant open and closed circuits loosely coupled inductively to each other, at both the transmitter and receiver, and all tuned to the same wave length, as described in his letters to Baker and his patent.

We think that Stone's original application sufficiently disclosed the desirability that the antenna circuits in transmitter and receiver be resonant to the same frequency as the closed circuits, as he expressly recommended in his patent. But in any event it is plain that no departure from or improper addition to the specifications was involved in the 1902 amendments, which merely made explicit what was already implicit. *Hobbs* v. *Beach*, 180 U. S. 383, 395-7. We would ordinarily be slow to recognize amendments made after the filing of Marconi's application and disclosing features shown in that application. Cf. *Schriber-Schroth Co.* v. *Cleveland Trust Co.*, 305 U. S. 47, 57; *Powers-Kennedy Corporation* v. *Concrete Co.*, 282 U. S. 175, 185-6; *Mackay Radio Co.* v. *Radio Corporation*, 306 U. S. 86. But here Stone's letters to Baker, whose authenticity has not been questioned in this case, afford convincing proof that Stone had conceived of the idea of tuning all four circuits prior to the date of Marconi's invention. Cf. *Bickell* v. *Smith-Hanbury-Scott Welding Co.*, 53 F. 2d 356, 358.

It is well established that as between two inventors priority of invention will be awarded to the one who by satisfying proof can show that he first conceived of the invention. *Philadelphia & Trenton Ry.* v. *Stimpson*, 14 Pet. 448, 462; *Loom Co.* v. *Higgins*, 105 U. S. 580, 593; *Radio Corporation* v. *Radio Laboratories*, 293 U. S. 1, 11-13; *Christie* v. *Seybold*, 55 Fed. 69, 76; *Automatic Weighing Mach. Co.* v. *Pneumatic Scale Corp.*, 158 Fed. 415, 417-22; *Harper* v. *Zimmermann*, 41 F. 2d 261, 265; *Sachs* v. *Hartford Electric Supply Co.*, 47 F. 2d 743, 748.

Commercial success achieved by the later inventor and patentee cannot save his patent from the defense of anticipation by a prior inventor.[20] Compare *Smith* v. *Hall*, 301 U. S. 216 with

[20] Even if the lack of invention in Marconi's improvement over Stone—making it stable the tuning of the antenna circuits which Stone had said should be tuned—could be said to be in sufficient doubt so that commercial

Smith v. *Snow*, 294 U. S. 1. To obtain the benefit of his prior conception, the inventor must not abandon his invention, *Gaylor* v. *Wilder*, 10 How. 477, 481, but must proceed with diligence to reduce it to practice. We think Stone has shown the necessary diligence. Compare *Radio Corporation* v. *Radio Laboratories*, *supra*, 13, 14. The delay until 1902 in including in his patent specifications the sentences already referred to, which explicitly provide for tuning of the antenna circuits, does not in the circumstances of this case show any abandonment of that feature of Stone's invention since, as we have seen, the idea of such tuning was at least implicit in his original application, and the 1902 amendments merely clarified that application's effect and purport.

Marconi's patent No. 763,772 was sustained by a United States District Court in *Marconi Wireless Telegraph Co.* v. *National*

---

success could aid in resolving the doubt, Thropp's Sons Co. v. Sieberling, 264 U. S. 319, 330; DeForest Radio Co. v. Electric Co., 283 U. S. 664, 685; Altoona Theatre v. Tri-Ergon Corp., 294 U. S. 477, 488, it has not been established that the alleged improvement contributed in any material degree to that success. Compare Altoona Theatre v. Tri-Ergon Corp., *supra*. Marconi's specifications disclose a large number of details of construction, none of which is claimed as invention in this patent, in which his apparatus differed from, and may have been greatly superior to, Stone's. Many of these formed the subject of prior patents. After his application for this patent, as well as before, Marconi made or adopted a great number of improvements in his system of wireless telegraphy. Two of his engineers have written that a major factor in his successful transmission across the Atlantic in December, 1901, was the use of much greater power and higher antennae than had previously been attempted, an improvement in no way suggested by the patent here in suit. Fleming, Electric Wave Telegraphy, 449-53; Vyvyan, Wireless Over Thirty Years, 22-33. Indeed both are agreed that in the actual transmission across the Atlantic tuning played no part; the receiver antenna consisted of a wire suspended by a kite which rose and fell with the wind, varying the capacity so much as to make tuning impossible. *Ibid.*

By 1913, when he testified in the National Electric Signalling Co. case, that "due to the utilization of the invention" of this patent he had successfully transmitted messages 6,600 miles, he had, after almost continuous experimentation, further increased the power used, developed new apparatus capable of use with heavy power, enlarged his antennae and adopted the use of horizontal, "directional" antennae, and made use of improved types of spark gaps and detecting apparatus, including the Fleming cathode-anode tube, the crystal detector, and sound recording of the signals—to mention but a few of the improvements made. He had also discovered that much greater distances could be attained at night. See Vyvyan, *supra*, 34-47, 55-60. The success attained by the apparatus developed by Marconi and his fellow engineers by continuous experimentation over a period of years—however relevant it might be in resolving doubts whether the basic four-circuit, tuned system disclosed by Marconi, and before him by Stone, involved invention—cannot, without further proof, be attributed in significant degree to any particular one of the many improvements made by Marconi over Stone during a period of years. The fact that Marconi's apparatus as a whole was successful does not entitle him to receive a patent for every feature of its structure.

Signalling Co., 213 Fed. 815, and his invention as specified in his corresponding British patent No. 7777 of 1900, was upheld in *Marconi* v. *British Radio & Telegraph Co.*, 27 T. L. R. 274, 28 R. P. C. 18. The French court likewise sustained his French patent, Civil Tribunal of the Seine, Dec. 24, 1912. None of these courts considered the Stone patent or his letters. All rest their findings of invention on Marconi's disclosure of a four circuit system and on his tuning of the four circuits, in the sense of rendering them resonant to the same frequency, in both of which respects Stone anticipated Marconi, as we have seen. None of these opinions suggests that if the courts had known of Stone's anticipation, they would have held that Marconi showed invention over Stone by making the tuning of his antenna circuit adjustable, or by using Lodge's variable inductance for that purpose. In *Marconi Wireless Telegraph Co.* v. *Kilbourne & Clark Mfg. Co.*, 229 Fed. 328, affirmed 265 Fed. 644, the district court held that the accused device did not infringe. While it entered formal findings of validity which the Circuit Court of Appeals approved, neither court's opinion discussed the question of validity and that question was not argued in the Circuit Court of Appeals.[21]

Marconi's reputation as the man who first achieved successful radio transmission rests on his original patent, which became reissue No. 11,913, and which is not here in question. That reputation, however well-deserved, does not entitle him to a patent for every later improvement which he claims in the radio field. Patent cases, like others, must be decided not by weighing the reputations of the litigants, but by careful study of the merits of their respective contentions and proofs. As the result of such a study

[21] A preliminary injunction restraining infringement was entered in Marconi Wireless Tel. Co. v. De Forest Tel. & Tel. Co., 225 Fed. 65, affirmed, 225 Fed. 373, both courts, without independent discussion of the validity of the patent, determining that the decision in the National Signalling Co. case justified the grant of preliminary relief. A preliminary injunction was also granted [illegible] Atlantic Communications Company, an action brought in the Eastern District of New York. Stone's letters were introduced in evidence in the Atlantic Communications Company case and the Kilbourne & Clark case. His deposition in the latter case, taken February 28 and 29, 1916, was incorporated in the record in this case. He there testified that he had refrained from producing proofs of the priority of his invention when called upon to testify in prior litigation in 1911 and 1914 because he wished the priority of his invention to be established by the owners of the patent, the Stone Telegraph Co. and its bondholders, in order to be sure that a bona fide defense would be made. He said that by 1915 [illegible], which he testified in the Atlantic Communications Co. case, he had concluded that the owners of the patent were not in a financial position to litigate, and that the Atlantic Co. "could make a bona fide Stone defense."

we are forced to conclude, without undertaking to determine whether Stone's patent involved invention, that the Court of Claims was right in deciding that Stone anticipated Marconi, and that Marconi's patent did not disclose invention over Stone. Hence the judgment below holding invalid the broad claims of the Marconi patent must be affirmed. In view of our interpretation of the Stone application and patent we need not consider the correctness of the court's conclusion that even if Stone's disclosures should be read as failing to direct that the antenna circuits be made resonant to a particular frequency, Marconi's patent involved no invention over Lodge, Tesla, and Stone.

Claim 16 of Marconi patent No. 763,772.

The Government asks us to review so much of the decision of the Court of Claims as held valid and infringed Claim 16 of Marconi's patent No. 763,772. That claim is for an antenna circuit at the receiver connected at one end to "an oscillation-receiving condactor" and at the other to a capacity (which could be the earth), containing the primary winding of a transformer, "means for adjusting the two transformer-circuits in electrical resonance with each other," and "an adjustable condenser in a shunt connected with the open circuit, and around said transformer-coil." Marconi thus discloses and claims the addition to the receiver antenna of an adjustable condenser connected in a shunt around the primary of the transformer. The specifications describe the condenser as "preferably one provided with two telescoping metallic tubes separated by a dielectric and arranged to readily vary the capacity by being slid upon each other". Marconi, however, makes no claim for the particular construction of the condenser.

Although the claim broadly provides for "means of adjusting the two transformer-circuits in electrical resonance", Marconi's drawings disclose the use of a variable inductance connected between the aerial conductor and the transformer-coil in such a manner that the variable inductance is not included in that part of the antenna circuit which is bridged by the condenser. The condenser is thus arranged in parallel with the transformer coil and in series with the variable inductance. In his specifications Marconi enumerates a number of preferred adjustments for tuning the transmitting and receiving stations, showing the precise equipment to be used to achieve tuning to the desired wave-length. The

two tunings which show the use of the adjustable condenser in the receiver antenna also make use of the variable inductance. And his specifications state: "In a shunt around said primary j^2 [the primary of the transformer] I usually place a condenser k . . . . An inductance coil g^1 of variable inductance is interposed in the primary circuit of the transformer, being preferably located between the cylinder f^2 [the aerial capacity] and the coil j^1."

In this respect the devices which the court below found to infringe Claim 16 exhibit somewhat different arrangements. Apparatus manufactured by the Kilbourne and Clark Company, and used by the Government, had a receiver antenna circuit containing a variable inductance in addition to the transformer coil, and having an adjustable condenser so constructed that it could be connected either in series with the two inductances, or in a shunt bridging both of them. Apparatus manufactured by the Telefunken Company showed a similar antenna having no variable inductance, but having an adjustable condenser so arranged that it could be connected either in series with the transformer coil, or in parallel with it by placing the condenser in a shunt circuit which would thus bridge all the inductance in the antenna circuit.

The Marconi patent does not disclose the function which is served by the adjustable condenser disclosed by Claim 16, except in so far as Marconi in his specifications, in describing the means of tuning the receiver circuits to a particular desired frequency, prescribes specific values for both the variable inductance and the adjustable condenser in the receiver antenna. The Court of Claims found that this indicated "that the purpose of the condenser connected in shunt with the primary winding of the transformer of the receiver, is to enable the electrical periodicity or tuning of the open circuit of the receiver to be altered".

The court thus based its holding that Claim 16 disclosed patentable invention on its finding that Marconi, by the use of an adjustable condenser in the antenna circuit, disclosed a new and useful method of tuning that circuit. The Government contends that the arrangement of the antenna circuit disclosed by Marconi's specifications—with the condenser shunted around the transformer coil but not around the variable inductance—is such that the condenser cannot increase the wave-length over what it would be without such a condenser, and that it can decrease that wave-length only when adjusted to have a very small capacity. The Government contends therefore that its principal function is

not that of tuning but of providing "loose coupling".[22] The Government does not deny that this precise arrangement is novel and useful, but it contends that its devices do not infringe that precise arrangement, and that Claim 16, if more broadly construed so as to cover its apparatus, is invalid because anticipated by the prior art, particularly the patents of Pupin and Fessenden.

As we have seen from our discussion of the other claims of the Marconi patent, the idea of tuning the antenna circuits involved no patentable invention. It was well known that tuning was achieved by the proper adjustment of either the inductance or the capacity in a circuit, or both. Lodge and Stone had achieved tuning by the use of an adjustable induction coil, so arranged that its effective inductance could readily be varied.

But capacity was no less important in tuning. De Tunzelmann's descriptions of Hertz's experiments show that Hertz, in order to make his receiving apparatus resonant to the particular frequency radiated by the transmitter, carefully determined the capacity of both, and indeed disclosed a means of adjusting the capacity of the receiver by attaching to it wires whose length could readily be varied. Marconi in his prior patent No. 586,193, granted July 13, 1897, which became reissue No. 11,913, had disclosed a two-circuit system for the transmission of radio waves in which both transmitter and receiver had large metal plates serving as capacity areas. His specifications describe the construction of transmitting and receiving stations so as to be resonant to the same frequency by calculation of the length of those metal plates, thereby determining the capacity of the antenna circuits of transmitter and receiver respectively. He states that the plates are "preferably of such a length as to be electrically tuned with the electric oscillations transmitted", and describes means of achieving this result so as to determine "the length most appropriate to the length of wave emitted by the oscillator". Claim 24 of his patent claims "the combination of a transmitter capable of producing electrical oscillations or rays of definite character at the will of the operator, and a receiver located at a distance and having a conductor tuned to respond to said oscillations . . .". The only means of achieving this tuning disclosed by the specifications is the determination

[22] See note 13, *supra*. Most of the current in the antenna circuit is said to pass through the condenser shunt and not through the transformer coil, thus minimizing the effect upon the frequency of vibrations in the antenna circuit of the magnetic stresses set up in the primary of the transformer by the current induced in the secondary.

of the capacity of the antenna of transmitter and receiver in the manner described.

Moreover the use of an adjustable condenser as a means of tuning was known to the prior art. Pupin in patent No. 640,515, applied for May 28, 1895, and granted January 2, 1900, before Marconi, disclosed the use of an adjustable condenser as a means of tuning a receiving circuit in a system of wired telegraphy. Pupin's patent was designed to permit the simultaneous transmission over a wire of several messages at different frequencies, and the selective reception at a given receiving station of the particular message desired, by tuning the receiving circuit to the frequency at which that message was transmitted. His specifications and drawings disclose at the receiver a telegraph key or other suitable detecting instrument located in a shunt from the wire along which the messages were passed. The shunt circuit included a condenser "of adjustable capacity", an adjustable induction coil, and a detecting instrument. His specifications state that "the capacity of the condenser H and the self-induction of the [induction] coil I being such that the natural period or frequency of the shunt or resonance circuit HI is the same as the period of one of the electromotive forces which produce the current coming over the line . . . this circuit HI will be in resonance with the current and therefore will act selectively with respect to it". He disclosed an alternative system in which a similar shunt circuit containing a condenser, already described as of adjustable capacity, and the primary of a transformer, was inductively coupled with another circuit containing the secondary of the transformer, an induction coil, an adjustable condenser, and a receiving device. He thus in effect disclosed an open receiving circuit with earth connection including the primary of an oscillation transformer—the secondary of which is connected in a circuit with a telegraph key or other suitable detecting instrument—and an adjustable condenser in a shunt bridging the primary of the transformer and thus connected in parallel with it.

Thus Pupin showed the use of an adjustable condenser as a means of tuning an electrical circuit so as to be selectively receptive to impulses of a particular frequency. It is true that his patent related not to the radio art but to the art of wired telegraphy, an art which employed much lower frequencies. But so far as we are informed the principles of resonance, and the methods of achieving it, applicable to the low frequencies used by

Pupin are the same as those applicable to the high frequency radio transmission and reception.

Fessenden, in patent No. 706,735, applied for Dec. 15, 1899, before Marconi, and granted Aug. 12, 1902, disclosed, in the antenna circuit of a radio receiver, a condenser in a shunt around a coil. The coil was used in effect as a transformer, by the magnetic lines of force set up when a current passed through it an indicator was caused to move, thereby either closing an electrical connection or giving a visible signal. Fessenden's specifications do not clearly disclose the purpose of his condenser, but they specify that it must be "of the proper size". He also discloses a condenser in a shunt circuit around the terminals of a spark gap in the antenna circuit of the transmitter, and his specifications prescribe that "This shunt-circuit must be tuned to the receiving-conductor; otherwise the oscillations produced by it will have no action upon the wave-responsive device at the receiving-station."

We have referred to the Pupin and Fessenden patents, not for the purpose of determining whether they anticipate Claim 16 of Marconi, as the Government insists, but to indicate the importance of considering them in that aspect, together with the relevant testimony, which the court below did not do. In the present state of the record we do not undertake to determine whether and to what extent these disclosures either anticipate Claim 16 of the Marconi patent or require that claim to be so narrowly construed that defendants' accused devices or some of them do not infringe Marconi.

Although the Pupin and Fessenden patents were in the record before the Court of Claims when it entered its decision finding Claim 16 valid and infringed, they were not referred to in connection with Claim 16 either in the court's opinion or in its findings, evidently because not urged upon that court by the Government as anticipating Claim 16. But this Court, in the exercise of its appellate power, is not precluded from looking at any evidence of record which, whether or not called to the attention of the court below, is relevant to and may affect the correctness of its decision sustaining or denying any contention which a party has made before it. *Muncie Gear Co.* v. *Outboard Motor Co.*, 315 U. S. 759, 766-8; Act of May 22, 1939, 28 U. S. C. § 2886; cf. *Hormel* v. *Helvering*, 312 U. S. 552, 556.

In order to determine whether this Court should consider the evidence which the Government now presses upon it, and should

on the basis of that evidence either decide for itself whether Claim 16 is valid and infringed or remand that question to the Court of Claims for further consideration, it is necessary to set out in some detail the relevant proceedings below. The case was referred to a special commissioner for the taking of testimony under a stipulation that the issue of reasonable compensation for damages and profits be postponed until the determination of the issues of validity and infringement. On June 26, 1933, the Commissioner filed a report in which he made the following findings with regard to Claim 16, which the Court of Claims later adopted in substance:

LXII. Claim 16 of Marconi # 763772 is directed to subject matter which is new and useful . . .

LXV. The receiving apparatus of the Kilbourne & Clark Company, shown in exhibit 95, and the receiver made by the Telefunken company, illustrated in exhibit 79, each has apparatus coming within the terminology of claim 16.

Both parties filed exceptions to the Commissioner's report. The Marconi Company excepted to part of finding LXII, and took several exceptions which were formally addressed to finding LXV. The Government, in a memorandum, opposed the suggested amendments to these findings. But the Government filed no exceptions to these two findings, nor did it, in its extensive brief before the Court of Claims, make any contention that Claim 16 either is invalid or was not infringed.

After the court had rendered its interlocutory decision holding Claim 16 valid and infringed, the case was sent back to the Commissioner to take evidence on the accounting. Much evidence was taken bearing on the function served by the condenser in the arrangement described in Claim 16 and in the Government's receivers, and in that connection the Pupin and Fessenden patents were again introduced in evidence by the Government. When the Pupin patent was offered the Commissioner stated: "Obviously, as I understand the offer of this patent of Pupin, it does not in any way attack the validity of Claim 16 of the Marconi patent in suit. As you state Mr. Blackmar, that has been decided by the Court, and I do not recall just now what procedure was followed after the decision and prior to the accounting proceeding; but the defendant had at that time opportunity for a motion for a new trial and presentation of newly-discovered evidence and all those matters." Accordingly, the Commissioner stated that he received the patent in evidence "for the sole purpose of aiding the wit-

ness and the Commissioner and the Court in an understanding of how the condenser in the Marconi patent operates." And in offering the Fessenden patent counsel for the Government similarly stated that it was offered "not to show invalidity but as showing justification for the defendant's use".

In its exceptions to the Commissioner's report on the accounting the Government asked the Court of Claims to make certain specific findings as to the mode of operation of the arrangements disclosed in the Pupin and Fessenden patents, and also to find that

"The mode of connecting the primary condenser in parallel with the antenna-to-earth capacity used by the defendant followed the disclosure of Pupin 640,516 and the Fessenden patent 706,735 . . . and hence does not infringe the Marconi claim 16 which is based upon a different arrangement, operating in a different manner to obtain a different result."

The Government contended that there was no finding of fact that Claim 16 had been infringed, and that the court, in the course of the accounting proceeding had by an order of October 22, 1937, reopened the entire subject of infringement. We agree with the court that the Commissioner's finding LXV, which the court adopted as finding LXIII, was a finding of infringement, and we see no reason to question the court's conclusion that its order had not reopened the subject of infringement.

In view, however, of the Government's apparent misunderstanding of the scope of the issues left open on the accounting we think that its request for a finding of non-infringement specifically addressed to the Pupin and Fessenden patents was a sufficient request to the court to reconsider its previous decision of infringement. And while most of the argument on the Government's exceptions to the Commissioner's report was based on evidence taken upon the accounting, the Government's briefs sufficiently disclosed to the court that the Pupin and Fessenden patents, at least, had been in the record prior to the interlocutory decision.

The court, in rejecting the Government's request for a finding of non-infringement stated: "The question of infringement of Marconi Claim 16 . . . is not before us in the present accounting." "The sole purpose and function of an accounting in a patent infringement case is to ascertain the amount of compensation due, and no other issue can be brought into the accounting to change or alter the court's prior decision." We cannot say

with certainty whether in rejecting the Government's request the court thought that it lacked power to reconsider its prior decision, or whether it held merely that in the exercise of its discretion it should not do so. Nor does it appear that, assuming it considered the question to be one of discretion, it recognized that in part at least the Government's request was based on evidence, having an important bearing on the validity and construction of Claim 16, which had been before the court but had not been considered by it when it held Claim 16 valid and infringed.

Although the interlocutory decision of the Court of Claims on the question of validity and infringement was appealable, *United States* v. *Esmault Pelterie*, 299 U. S. 201, 303 U. S. 26; 28 U. S. C. § 288 (b), as are interlocutory orders of district courts in suits to enjoin infringement, 28 U. S. C. § 227 (a); *John Simmons Co.* v. *Grier Bros. Co.*, 258 U. S. 82, 89, the decision was not final until the conclusion of the accounting. *Barnard* v. *Gibson*, 7 How. 649; *Hunnewell* v. *Stainthorp*, 2 Wall. 106; *Simmons Co.* v. *Grier Bros. Co.*, *supra*, 89. Hence the court did not lack power at any time prior to entry of its final judgment at the close of the accounting to reconsider any portion of its decision and reopen any part of the case. *Perkins* v. *Fourniquet*, 6 How. 206, 208; *McGourkey* v. *Toledo and Ohio Ry.*, 146 U. S. 536, 544; *Simmons Co.* v. *Grier Bros Co.*, *supra*, 90-91. It was free in its discretion to grant a reargument based either on all the evidence then of record or only the evidence before the court when it rendered its interlocutory decision, or to reopen the case for further evidence.

Whether it should have taken any of these courses was a matter primarily for its discretion, to be exercised in the light of various considerations which this Court cannot properly appraise without more intimate knowledge than it has of the proceedings in a long and complex trial. Among those considerations are the questions whether, as appears to be the case from such portions of the record as have been filed in this Court or cited to us by counsel, the Government failed to make any contention as to the validity or construction of Claim 16 in the proceedings leading to the interlocutory decision; whether the showing of noninfringement which it now makes is sufficiently strong, and the public interest that an invalid patent be not sustained is sufficiently great, to justify reconsidering the decision as to Claim 16 despite the failure of Government counsel to press its contention at the proper time; whether adequate consideration of the question of noninfringement can be had on the existing record, or whether additional tes-

timony should be received; and whether, balancing the strength or weakness of the Government's present showing of noninfringement against the undesirability of further prolonging this already extended litigation, the case is one which justifies reconsideration.

These are all matters requiring careful consideration by the trial court. In order that the case may receive that consideration, we vacate the judgment as to Claim 16 and remand the cause to the Court of Claims for further proceedings in conformity to this opinion.

If on the remand, the court should either decline to reconsider its decision of infringement, or should upon reconsideration adhere to that decision, it should pass upon the contention of the Government, urged here and below, as to the measure of damages, with respect to which the court made no findings. The Government's contention is that the variable capacity shunt of the accused devices bridged all the inductance in the receiving antenna circuit, and that even though those devices infringed they nevertheless embody an improvement over Marconi's Claim 16, in which only the transformer coil was bridged. In computing the damages the court measured them by 65% of the cost to the Government of the induction coils which would be required to replace in the accused devices the adjustable condensers as a means of tuning, taking into account the greater convenience and efficiency of condenser tuning. The allowance of only 65% was on the theory that if the parties had negotiated for the use of the invention the price would have been less than the cost to the Government of the available alternative means of tuning.

In computing the damages the court apparently did not take into account or attempt to appraise any contribution which may have been made by the improvement over Marconi which the Government asserts was included in the accused devices. The court found that where the condenser is connected in series with the inductance coils in the antenna it "can be used to shorten the natural resonant wave length of the antenna circuit but cannot lengthen it beyond what would be the resonant wave length if the condenser were not present." On the other hand, it found that when the condenser is connected in parallel it enables the periodicity of the antenna to be lowered, permitting the reception of longer wave lengths.

The computation of damages was based on the premise that the advantage to the Government resulting from the infringement was

derived from the ability which the accused devices had thus acquired to receive longer wave lengths. But there was substantial testimony that the arrangement disclosed by Marconi's specifications was in effect a connection in series which did not make possible reception of longer wave lengths, as did the arrangement in the accused devices. And the court nowhere found that the arrangement covered by Marconi's Claim 16 did make possible such reception. The appropriate effect to be given to this testimony is important in the light of the recognized doctrine that if a defendant has added "non-infringing and valuable improvements which had contributed to the making of the profits", it is not liable for benefits resulting from such improvements. *Westinghouse* v. *Wagner Mfg. Co.*, 225 U. S. 604, 614-15, 616-17; *Sheldon* v. *Metro-Goldwyn Corp.*, 309 U. S. 390, 402-406, and cases cited. Finding LXIII that the Government was using "apparatus coming within the terminology of Claim 16", and Finding 23 on the accounting that the accused devices "infringe Claim 16 of the Marconi patent", give no aid in solving this problem for they are not addressed to the question whether, assuming infringement, the Government has made improvements which, of themselves are non-infringing. That can only be afforded by findings which appraise the evidence, establish the scope of Marconi's claim and the nature and extent of the difference in function, if any, between the device claimed by Marconi and those used by the Government, and determine whether any differences shown to exist constitute a "non-infringing improvement" for which Marconi deserves no credit.

The judgment as to Claim 16 will be vacated and the cause remanded for further proceedings.

The Fleming Patent No. 803,684

The Fleming patent, entitled "Instrument for Converting Alternating Electric Currents into Continuous Currents" was applied for April 19, 1905, and granted on November 7, 1905 to the Marconi Company, as assignee of Fleming. Its specifications state that "this invention relates to certain new and useful devices for converting alternating electric currents, and especially high-frequency alternating electric currents or electric oscillations, into continuous electric currents for the purpose of making them detectable by and measurable with ordinary direct-current instruments, such as a mirror galvanometer of the usual type or any ordinary direct-current ammeter". Fleming's drawings and specifications show a

combination apparatus by which alternating current impulses received through an antenna circuit containing the primary of a transformer are induced in the secondary of the transformer. To one end of the secondary coil is connected a carbon filament like that of an incandescent electric lamp, which is heated by a battery. Surrounding, but not touching the filament, is a cylinder of aluminum open at the top and bottom, which is connected with the other end of the secondary. The cylinder and filament are enclosed in an evacuated vessel such as an ordinary electric lamp bulb. An indicating instrument or galvanometer is so located in this circuit as to respond to the flow of current in it. The specifications explain the operation of this device:

"This arrangement described above operates as an electric valve and permits negative electricity to flow from the hot carbon *b* to the metal cylinder *c*, but not in the reverse direction, so that the alternations induced in the coil *k* by the Hertzian waves received by the aerial wire *n* are rectified or transformed into a more or less continuous current capable of actuating the galvanometer *l* by which the signals can be read."

The specifications further state:

". . . the aerial wire *n* may be replaced by any circuit in which there is an alternating electromotive force, whether of low frequency or of high frequency . . ."

"Hence the device may be used for rectifying either high-frequency or low-frequency alternating currents of electrical oscillations . . .".

Only Claims 1 and 37 of the patent are in suit. They read as follows:

"1. The combination of a vacuous vessel, two conductors adjacent to but not touching each other in the vessel, means for heating one of the conductors, and a circuit outside the vessel connecting the two conductors.

"37. At a receiving-station in a system of wireless telegraphy employing electrical oscillations of high frequency a detector comprising a vacuous vessel, two conductors adjacent to but not touching each other in the vessel, means for heating one of the conductors, a circuit outside of the vessel connecting the two conductors, means for detecting a continuous current in the circuit, and means for impressing upon the circuit the received oscillations."

The current applied to the filament or cathode by the battery sets up a flow of electrons (negative electric charges) from the heated cathode, which are attracted to the cold plate or anode when the latter is positively charged. When an alternating current

is set up in the circuit containing the cathode, anode, and secondary of the transformer, the electronic discharge from the cathode closes the circuit and permits a continuous flow of electricity through it when the phase of the current is such that the anode is positively charged, while preventing any flow of current through the tube when the anode is negatively charged. The alternating current is thus rectified so as to produce a current flowing only in one direction. *See DeForest Radio Co.* v. *General Electric Co.*, 283 U. S. 664; *Radio Corporation* v. *Radio Laboratories*, 293 U. S. 1; *Detrola Corporation* v. *Hazeltine Corporation*, 313 U. S. 259.

Claims 1 and 37 of the Fleming patent are identical in their structural elements. Both claim the vacuum tube, and the two electrodes connected by a circuit outside the tube, one element being heated. The claims differ only in that Claim 37 includes "means for detecting" the continuous or direct current in the anode-cathode circuit, and "means for impressing upon the circuit the received oscillations" from the transformer coil of the antenna circuit.

In the patent as originally issued there had been another difference between the two claims. Claim 37 describes the tube as being used "in a system of wireless telegraphy employing oscillations of high frequency". No such limitation was placed on Claim 1 as originally claimed, and the specifications already quoted plainly contemplated the use of the claimed device with low as well as high frequency currents. This distinction was eliminated by a disclaimer filed by the Marconi Company November 17, 1915, restricting the combination of the elements of Claim 1 to a use "in connection with high frequency alternating electric currents or electric oscillations of the order employed in Hertzian wave transmission", and deleting certain references to low frequencies in the specifications. The result of the disclaimer was to limit both claims to the use of the patented device for rectifying high frequency alternating waves or currents such as were employed in wireless telegraphy.

The earliest date asserted for Fleming's invention, as limited by the disclaimer, is November 16, 1904. Twenty years before, on October 21, 1884, Edison had secured United States Patent No. 307,031. In his specifications he stated:

> I have discovered that if a conducting substance is interposed in the vacuous space within the globe of an incandescent electric lamp, and said conducting substance is connected outside of the lamp with one terminal, preferably the positive

one, of the incandescent conductor, a portion of the current will, when the lamp is in operation, pass through the shunt-circuit thus formed, which shunt includes a portion of the vacuous space within the lamp. This current I have found to be proportional to the degree of incandescence of the conductor or candle-power of the lamp."

Edison proposed to use this discovery as a means of "indicating, variations in the electro-motive force in an electric circuit," by connecting a lamp thus equipped at a point where the current was to be measured. The drawings of his patent show an electric circuit, including a filament (cathode) and a plate (anode) both "in the vacuous space within the globe"—an electric light bulb. The shunt-circuit extends from the plate through a galvanometer to the filament. His specifications disclose that the vacuous space within the globe is a conductor of current between the plate anode and the filament; that the strength of the current in the filament-to-plate circuit through the vacuum depends upon the degree of incandescence at the filament; and that the plate anode is preferably connected to the positive side of the current supply. The claims of the patent are for the combination of the filament, plate and interconnecting circuit, including the galvanometer. Claim 5, a typical claim, reads as follows:

"The combination, with an incandescent electric lamp, of a circuit having one terminal in the vacuous space within the globe of said lamp, and the other connected with one side of the lamp-circuit, and electrically controlled or operated apparatus in said circuit, substantially as set forth."

The structure disclosed in Fleming's Claims 1 and 37 thus differed in no material respect from that disclosed by Edison. Since Fleming's original Claim 1 is merely for the structure, it reads directly on Edison's Claim 5 and could not be taken as invention over it.

Fleming used this structure for a different purpose than Edison. Edison disclosed that his device operated to pass a current across the vacuous space within the tube between filament and plate. He used this current as a means of measuring the current passing through the filament circuit. Fleming, in his specifications, disclosed the use of his tube as a rectifier of alternating currents, and in Claim 37 he claimed the use of that apparatus as a means of rectifying alternating currents of radio frequency. But in this use of the tube to convert alternating into direct

currents there was no novelty for it had been disclosed by others and by Fleming himself long before Fleming's invention date.

On January 9, 1890, ten years before Fleming filed his application, he stated in a paper read before the Royal Society of London:

"It has been known for some time that if a platinum plate or wire is sealed through the glass bulb of an ordinary carbon filament incandescent lamp, this metallic plate being quite out of contact with the carbon conductor, a sensitive galvanometer connected between this insulated metal plate enclosed in the vacuum and the external *positive* electrode of the lamp indicates a current of some milliampères passing through it when the lamp is set in action, but the same instrument when connected between the *negative* electrode of the lamp and the insulated metal plate indicates no sensible current. This phenomenon in carbon incandescence lamps was first observed by Mr. Edison, in 1884, and further examined by Mr. W. H. Preece, in 1885." Proceedings of the Royal Society of London, vol. 47, pp. 118-9.

Fleming's 1890 paper further pointed out that the vacuous space "possesses a curious unilateral conductivity"; that is, it permits current to "flow across the vacuous space from the hot carbon [cathode] to the cooler metal plate [anode], but not in the reverse direction." *Id.* 122. He noted the ability of the tube to act as a rectifier of alternating current, saying:

"When the lamp is actuated by an *alternating* current a *continuous* current is found flowing through a galvanometer, connected between the insulated plate and *either* terminal of the lamp. The direction of the current through the galvanometer is such as to show that negative electricity is flowing from the plate through the galvanometer to the lamp terminal." *Id.* 120.

Fleming's paper thus noted, contrary to the then popular conception, that it is negative electricity which flows from cathode to anode, but he emphasized that even this had been a part of general scientific knowledge, as follows:

"The effect of heating the negative electrode in facilitating discharge through vacuous spaces has previously been described by W. Hittorf ('Annalen der Physik und Chemie,' vol. 21, 1884, p. 90-139), and it is abundantly confirmed by the above experiments. We may say that a vacuous space bounded by two electrodes—one incandescent and the other cold—possesses a unilateral conductivity for electric discharge when these electrodes are within a distance of the mean free path of projection of the molecules which the impressed electromotive force can detach and send off from the hot negative electrode.

"This unilateral conductivity of vacuous spaces having unequally heated electrodes has been examined by MM. Elster and Geitel (see 'Wiedemann's Annalen,' vol. 38, 1889, p. 40), and also by Goldstein ('Wied. Ann.,' vol. 24, 1885, p. 83), who in experiments of various kinds have demonstrated that when an electric discharge across a vacuous space takes place from a carbon conductor to another electrode the discharge takes place at lower electromotive force when the carbon conductor is the negative electrode and is rendered incandescent." *Id.* 125-6.

Fleming's reference in this publication to the unilateral conductivity of the vacuous space between cathode and anode, and the consequent ability of the two to derive a continuous unidirectional current from an alternating current was a recognition that the Edison tube embodying the structure described could be used as a rectifier of alternating current. This knowledge, disclosed by publication more than two years before Fleming's application, was a bar to any claim for a patent for an invention embodying the published disclosure. R. S. §§ 4886, 4920; 35 U. S. C. § 31, 69. *Wagner* v. *Meccano Ltd.*, 246 Fed. 603, 607; cf. *Muncie Gear Co.* v. *Outboard Co.*, *supra*, 766.

It is unnecessary to decide whether Fleming's use of the Edison device for the purpose of rectifying high frequency Hertzian waves as distinguished from low frequency waves, involved invention over the prior art, or whether the court below rightly held that the devices used by the Government did not infringe the claims sued upon, for we are of the opinion that the court was right in holding that Fleming's patent was rendered invalid by an improper disclaimer. It is plain that Fleming's original Claim 1, so far as applicable to use with low frequency alternating currents, involved nothing new, as Fleming himself must have known in view of his 1890 paper, and as he recognized by his disclaimer in 1915, made twenty-five years after his paper was published and ten years after his patent had been allowed. Its invalidity would defeat the entire patent unless the invalid portion had been claimed "through inadvertence, accident, or mistake, and without any fraudulent or deceptive intention", and was also disclaimed without "unreasonable" neglect or delay. R. S. §§ 4917, 4922, 35 U. S. C. §§ 65, 71; *Enston* v. *Simon Ascher & Co.*, 282 U. S. 445, 452; *Altoona Theatres* v. *Tri-Ergon Corp.*, 294 U. S. 477, 493; *Maytag* v. *Harley Co.*, 307 U. S. 243.

We need not stop to inquire whether, as the Government contends, the subject matter of the disclaimer was improper as in

effect adding a new element to the claim. See *Milcor Steel Co.* v. *Fuller Co.*, 316 U. S. 143, 147-8. For we think that the court below was correct in holding that the Fleming patent was invalid because Fleming's claim for "more than he had invented" was not inadvertent, and his delay in making the disclaimer was "unreasonable". Both of these are questions of fact, but since the court in its opinion plainly states its conclusions as to them, and those conclusions are supported by substantial evidence, its omission to make formal findings of fact is immaterial. Act of May 22, 1939, 53 Stat 752, 28 U. S. C. § 288(b); cf. *American Propeller Co* v. *United States*, 300 U. S. 475, 479-80; *Great Lakes Dredge & Dock Co.* v. *Huffman*, No. 849, May 24, 1943.

The purpose of the rule that a patent is invalid in its entirety if any part of it be invalid is the protection of the public from the threat of an invalid patent, and the purpose of the disclaimer statute is to enable the patentee to relieve himself from the consequences of making an invalid claim if he is able to show both that the invalid claim was inadvertent and that the disclaimer was made without unreasonable neglect or delay. *Easten* v. *Simon Ascher & Co., supra.* Here the patentee has sustained neither burden.

Fleming's paper of 1890 showed his own recognition that his claim of use of his patent for low frequency currents was anticipated by Edison and others. It taxes credulity to suppose, in the face of this publication, that Fleming's claim for use of the Edison tube with low frequency currents was made "through inadvertence, accident or mistake", which is prerequisite to a lawful disclaimer. No explanation or excuse is forthcoming for his claim of invention of a device which he had so often demonstrated to be old in the art, and which he had specifically and consistently attributed to Edison. Nor is any explanation offered for the delay of the patentee—the Marconi Company—in waiting ten years to disclaim the use of the device with low frequency currents and to restrict it to a use with high frequency Hertzian waves which Edison had plainly foreshadowed but not claimed. For ten years the Fleming patent was held out to the public as a monopoly of all its claimed features. That was too long in the absence of any explanation or excuse for the delay, and hence in this case was long enough to invalidate the patent. The conclusion of the Court of Claims not only has support in the

evidence, but we can hardly see how on this record any other could have been reached.

The Marconi Company's contention that it nowhere appears that Fleming was not the first inventor of the use of the patented device to rectify high frequency alternating currents is irrelevant to the question of the sufficiency of the disclaimer. The disclaimer itself is an assertion that the claimed use of the invention with low frequencies was not the invention of the patentee, whose rights were derived wholly from Fleming. This improper claim for something not the invention of the patentee rendered the whole patent invalid unless saved by a timely disclaimer which was not made.

The Marconi Company also asserts that, as it is suing as assignee of the patentee, it is unaffected by the provisions of the disclaimer statutes, which it construes as restricting to the "patentee" the consequences of unreasonable delay in making the disclaimer and as exempting the assignee from those consequences by the sentence "But no patentee shall be entitled to the benefits of this section if he has unreasonably neglected or delayed to enter a disclaimer". 35 U. S. C. 71. As the court below found, the Marconi Company was itself the patentee to whom the patent was issued on the assignment of Fleming's application in conformity to 35 U. S. C. § 44. The right given by § 71 to the patentee or his assignees to sue for infringement upon a proper disclaimer obviously does not relieve the patentee from the consequences of his failure to comply with the statute because he acquired his patent under an assignment of the application. *Altoona Theatres* v. *Tri-Ergon Corp., supra; Maytag Co.* v. *Hurley Co., supra; France Mfg. Co.* v. *Jefferson Electric Co.*, 106 F. 2d 605, 610. Such a contention is not supported by the words of the statute and if allowed would permit the nullification of the disclaimer statute by the expedient of an assignment of the application. We need not consider whether one who has taken an assignment of a patent after its issuance would have any greater rights than his assignor in the event of the latter's undue delay in filing a disclaimer. Compare *Apex Electrical Mfg. Co.* v. *Maytag Co.*, 122 F. 2d 182, 189.

The judgment in No. 373 is vacated and the cause remanded to the Court of Claims for further proceedings not inconsistent with this opinion.

The judgment in No. 369 is affirmed.

So ordered.

Mr. Justice MURPHY took no part in the consideration or decision of this case.

SUPREME COURT OF THE UNITED STATES.

Nos. 369, 373.—October Term, 1942.

369	Marconi Wireless Telegraph Company of America, Petitioner, *vs.* The United States.	On Writs of Certiorari to the Court of Claims.
373	The United States, Petitioner, *vs.* Marconi Wireless Telegraph Company of America.	

[June 21, 1943.]

Mr. Justice Frankfurter, dissenting in part.

I regret to find myself unable to agree to the Court's conclusion regarding the invalidity of the broad claims of Marconi's patent. Since broad considerations control the significance and assessment of the details on which judgment in the circumstances of a case like this is based, I shall indicate the general direction of my views.

It is an old observation that the training of Anglo-American judges ill fits them to discharge the duties cast upon them by patent legislation.[1] The scientific attainments of a Lord Moulton are perhaps unique in the annals of the English-speaking judiciary. However, so long as the Congress, for the purposes of patentability, makes the determination of originality a judicial function, judges must overcome their scientific incompetence as best they can. But consciousness of their limitations should make them

[1] "Considering the exclusive right to invention as given not of natural right, but *for* the benefit of society, I know well the difficulty of drawing a line between the things which are worth to the public the embarrassment of an exclusive patent, and those which are not. As a member of the patent board for several years, while the law authorized a board to grant or refuse patents, I saw with what slow progress a system of general rules could be matured. . . . Instead of refusing a patent in the first instance, as the board was authorized to do, the patent now issues of course, subject to be declared void on such principles as should be established by the courts of law. This business, however, is but little analogous to their course of reading, since we might in vain turn over all the lubberly volumes of the law to find a single ray which would lighten the path of the mechanic or the mathematician. It is more within the information of a board of academical professors, and a previous refusal of patent would better guard our citizens against harassment by law suits. But England had given it to her judges, and the usual predominancy of her examples carried it to ours." Thomas Jefferson to Mr.

vigilant against importing their own notions of the nature of the creative process into Congressional legislation, whereby Congress "to promote the Progress of Science and useful Arts" has secured "for limited Times to . . . Inventors the exclusive Right to their . . . Discoveries." Above all, judges must avoid the subtle temptation of taking scientific phenomena out of their contemporaneous setting and reading them with a retrospective eye.

The discoveries of science are the discoveries of the laws of nature, and like nature do not go by leaps. Even Newton and Einstein, Harvey and Darwin, built on the past and on their predecessors. Seldom indeed has a great discoverer or inventor wandered lonely as a cloud. Great inventions have always been parts of an evolution, the culmination at a particular moment of an antecedent process. So true is this that the history of thought records striking coincidental discoveries—showing that the new insight first declared to the world by a particular individual was "in the air" and ripe for discovery and disclosure.

The real question is how significant a jump is the new disclosure from the old knowledge. Reconstruction by hindsight, making obvious something that was not at all obvious to superior minds until someone pointed it out,—this is too often a tempting exercise for astute minds. The result is to remove the opportunity of obtaining what Congress has seen fit to make available.

The inescapable fact is that Marconi in his basic patent hit upon something that had eluded the best brains of the time working on the problem of wireless communication—Clerk Maxwell and Sir Oliver Lodge and Nikola Tesla. Genius is a word that ought to be reserved for the rarest of gifts. I am not qualified to say whether Marconi was a genius. Certainly the great eminence of Clerk Maxwell and Sir Oliver Lodge and Nikola Tesla in the field in which Marconi was working is not questioned.

Isaac M'Pherson, August 13, 1813, Works of Thomas Jefferson, Wash. Ed., vol. VI, pp. 181-82.

"I cannot stop without calling attention to the extraordinary condition of the law which makes it possible for a man without any knowledge of even the rudiments of chemistry to pass upon such questions as these. The inordinate expense of time is the least of the resulting evils, for only a trained chemist is really capable of passing upon such facts, e. g., in this case the chemical character of Von Furth's so-called "zinc compound," or the presence of inactive organic substances. . . . How long we shall continue to blunder along without the aid of unpartisan and authoritative scientific assistance in the administration of justice, no one knows; but all fair persons not conventionalized by provincial legal habits of mind ought, I should think, unite to effect some such advance." Judge Learned Hand in Parke-Davis & Co. v. Mulford Co., 189 Fed. 95, 115 (1911).

They were, I suppose, men of genius. The fact is that they did not have the "flash" (a current term in patent opinions happily not used in this decision) that begot the idea in Marconi which he gave to the world through the invention embodying the idea. But it is now held that in the important advance upon his basic patent Marconi did nothing that had not already been seen and disclosed.

To find in 1943 that what Marconi did really did not promote the progress of science because it had been anticipated is more than a mirage of hindsight. Wireless is so unconscious a part of us, like the automobile to the modern child, that it is almost impossible to imagine ourselves back into the time when Marconi gave to the world what for us is part of the order of our universe. And yet, because a judge of unusual capacity for understanding scientific matters is, by a process of intricate ratiocination, able to demonstrate that anyone could have drawn precisely the inferences that Marconi drew and that Stone hinted at [illegible] on paper, the Court finds that Marconi's patent was invalid although nobody except Marconi did in fact draw the right inferences that were embodied into a workable boon for mankind. For me it speaks volumes that it should have taken forty years to reveal the fatal bearing of Stone's relation to Marconi's achievement by a retrospective reading of his application to mean this rather than that. This is for me, and I say it with much diffidence, too easy a transition from what was not to what became.

I have little doubt, in so far as I am entitled to express an opinion, that the vast transforming forces of technology have rendered obsolete much in our patent law. For all I know the basic assumption of our patent law may be false, and inventors and their financial backers do not need the incentive of a limited monopoly to stimulate invention. But whatever revamping our patent laws may need, it is the business of Congress to do the revamping. We have neither constitutional authority nor scientific competence for the task.

Mr. Justice ROBERTS joins in this opinion.

SUPREME COURT OF THE UNITED STATES.

Nos. 369, 373.—October Term, 1942.

Marconi Wireless Telegraph Company of America, Petitioner, 369 *vs.* The United States. The United States, Petitioner, 373 *vs.* Marconi Wireless Telegraph Company of America.	On Writs of Certiorari to the Court of Claims.

[June 21, 1943.]

Mr. Justice Rutledge, dissenting in part.

Until now law[1] has united with almost universal repute[2] in acknowledging Marconi as the first to establish wireless telegraphy on a commercial basis. Before his invention, now in issue,[3] etherborne communication traveled some eighty miles. He lengthened the arc to 6,000. Whether or not this was "inventive" legally, it was a great and beneficial achievement.[4] Today, forty years after

R. 688; *Société* Marconi v. *Société Générale*, etc., Civil Tribunal of the Seine, 3d Chamber, Dec. 24, 1912; Marconi Wireless Telegraph Co. of America v. National Electric Signalling Co., 213 Fed. 815 (D. C.); Marconi Wireless Telegraph Co. of America v. Kilbourne & Clark Mfg Co., 265 Fed. 644 (C. C. A.), aff'g 239 Fed. 328 (D. C.)

[2] Cf., e. g., 14 Encyc. Britannica (14th ed.) 869.

[3] His earliest American patent, U. S. Patent No. 586,193, granted on July 13, 1897, later becoming Reissue Patent No. 11,913, is not in suit here. That patent did not embrace many of the crucial claims here involved and its product cannot compare in commercial usefulness with that of the patent in suit.

[4] Courts closer to it chronologically than we are have characterized it as a "conspicuous advance in wireless telegraphy"; "a real accomplishment" and the ideas involved in the patent were said to "have proven of great value to the world," to have brought about "an entirely new and useful result," "a new and very important industrial result" and "a wonderful conquest." "The Marconi patent stands out as an unassailable monument until new discoveries are made." Cf. the authorities cited in note 1, *supra*.

the event, the Court's decision reduces it to an electrical mechanic's application of mere skill in the art.

By present knowledge, it would be no more. School boys and mechinics now could perform what Marconi did in 1900. But before then wizards had tried and failed. The search was at the pinnacle of electrical knowledge. There, seeking, among others, were Tesla, Lodge and Stone, old hands and great ones. With them was Marconi, still young as the company went,[2] obsessed with youth's zeal for the hunt.

At such an altitude, to work at all with success is to qualify for genius, if that is important. And a short step forward gives evidence of inventive power. For at that height a merely slight advance comes through insight only a first-rate mind can produce. This is so, whether it comes by years of hard work tracking down the sought secret or by intuition flashed from subconsciousness made fertile by long experience or shorter intensive concentration. At this level and in this company Marconi worked and won.

He won by the test of results. No one disputes this. His invention had immediate and vast success, where all that had been done before, including his own work, gave but narrowly limited utility. To make useful improvement at this plane, by such a leap, itself shows high capacity. And that is true, although it was inherent in the situation that Marconi's success should come by only a small margin of difference in conception. There was not room for any great leap of thought, beyond what he and others had done, to bring to birth the practical and useful result. The most eminent men of the time were conscious of the problem, were interested in it, had sought for years the exactly right arrangement, always approaching more nearly but never quite reaching the stage of practical success. The invention was, so to speak, hovering in the general climate of science, momentarily awaiting birth. But just the right releasing touch had not been found. Marconi added it.

When to altitude of the plane of conception and results so immediate and useful is added well-nigh unanimous contemporary judgment, one who long afterward would overturn the invention assumes a double burden. He undertakes to overcome what

[2] He was only twenty-six years old at the time he applied for the patent in suit, but he had already made substantial contributions to the field.

would offer strong resistance fresh in its original setting. He seeks also to overthrow the verdict of time. Long-range retroactive diagnosis, however competent the physician, becomes hazardous by progression as the passing years add distortions of the past and destroy its perspective. No light task is accepted therefore in undertaking to overthrow a verdict settled so long and so well, and especially one so foreign to the art of judges.

In lawyers' terms this means a burden of proof, not insurmountable, but inhospitable to implications and inferences which in less settled situations would be permissible to swing the balance of judgment against the claimed invention. That Marconi received patents elsewhere which, once established, have stood the test of time as well as of contemporary judgment, and secured his American patent only after years were required to convince our office he had found what so many others sought, but emphasizes the weight and clarity of proof required to overcome his claim.

Marconi received patents here in England, and in France.[6] The American patent was not issued perfunctorily. It came forth only after a long struggle had brought about reversal of the Patent Office's original and later rejections. The application was filed in November, 1900. In December it was rejected on Lodge,[7] and an earlier patent to Marconi.[8] It was amended and again rejected. Further amendments followed and operation of the system was explained. Again rejection took place, this time on Lodge, the earlier Marconi, Braun and other patents. After further proceedings, the claims were rejected on Tesla.[9] A year elapsed, but in March, 1904, reconsideration was granted. Some claims then were rejected on Stone,[10] others were amended, still others were cancelled, and finally on June 28, 1904, the patent issued. French and British patents had been granted in 1900.

Litigation followed at once. Among Marconi's American victories were the decisions cited above.[11] Abroad the results were similar.[12] Until 1935, when the Court of Claims held it invalid

in this case, 81 Ct. Cl. 671, no court had found Marconi's patent wanting in invention. It stood without adverse judicial decision for over thirty years. In the face of the burden this history creates, we turn to the references, chiefly Tesla, Lodge and Stone. The Court relies principally on Stone, but without deciding whether this was inventive.

It is important, in considering the references, to state the parties' contentions concisely. The Government's statement is that they differ over whether Marconi was first to conceive four-circuit "tuning" for transmission of sound by Hertzian waves. It says this was taught previously by Tesla, Lodge and Stone. Petitioner however says none of them taught what Marconi did. It contends that Marconi was the first to accomplish the kind of tuning he achieved, and in effect urges this was patentably different from other forms found earlier.

Specifically petitioner urges that Tesla had nothing to do with either Hertzian waves or tuning, but in fact his transmitting and receiving wires could not be tuned.[13] Lodge, it claims, disclosed a tuned antenna, for either transmitter or receiver or both, but the closed circuits associated with the antenna ones were not tuned. Finally it is said Stone does not describe tuning the antenna, but does show tuning of the associated closed circuit. And Marconi tuned both.

Petitioner does not claim the general principles of tuning. It admits they had long been familiar to physicists and that Lodge and others fully understood them. But it asserts Lodge did not know what circuits should be tuned, to accomplish what Marconi achieved, and that, to secure this, "knowledge that tuning is possible is not enough—there is also required the knowledge of whether or not to tune and how much."

Likewise, petitioner does not deny that Stone knew and utilized the principles of tuning, but urges, with respect to the claim he applied them to all of the four circuits, that the only ones tuned,

[13] Tesla in fact did not use Hertzian waves. His idea was to make the ether a conductor for long distances by using extremely high voltage, 20,000,000 to 30,000,000 volts, and extremely high altitudes, 30,000 to 40,000 feet or more, to secure transmission from aerial to aerial. Balloons, with wires attached reaching to the ground, were his suggested aerials. His system was really one for transmitting power for motors, lighting, etc., to "any terrestrial distance," though he incidentally mentions "intelligible messages." As he did not use Hertzian waves, he had no such problem of selectivity as Marconi, Lodge, Stone and others were working on later.

in his original application, were the closed circuits and therefore that the antenna circuits were not tuned; although it is not denied that the effects of tuning the closed circuits were reflected in the open ones by what Stone describes as "producing *forced* simple harmonic electric vibrations of the same periodicity in an elevated conductor."

The Stone amendments of 1902, made more than a year after Marconi's filing date, admittedly disclose tuning of both the closed and the open circuits, and were made for the purpose of stating expressly the latter effect, claimed to be implicit in the original application. Petitioner denies this was implicit and argues, in effect, that what Stone originally meant by "producing *forced* . . . vibrations" was creating the desired effects in the antenna *by force*, not by tuning; and therefore that the two methods were patentably different.

It seems clear that the parties use the word "tuning" to mean different things and the ambiguity, if there is one, must be resolved before the crucial questions can be stated with meaning. It will aid, in deciding whether there is ambiguity or only confusion, to consider the term and the possible conceptions it may convey in the light of the problems Marconi and Stone, as well as other references, were seeking to solve.

Marconi had in mind first a specific difficulty, as did the principal references. It arose from what, to the time of his invention, had been a baffling problem in the art. Shortly and simply, it was that an electrical circuit which is a good conserver of energy is a bad radiator and, conversely, a good radiator is a bad conserver of energy. Effective use of Hertzian waves over long distances required both effects. To state the matter differently, Lodge had explained in 1894 the difficulties of fully utilizing the principle of sympathetic resonance in detecting ether waves. To secure this, it was necessary, on the one hand, to discharge a long series of waves of equal or approximately equal length. Such a series can be produced only by a circuit which conserves its energy well, what Marconi calls a persistent oscillator. On the other hand, for distant detection, the waves must be of substantial amplitude, and only a circuit which loses its energy rapidly can transmit such waves with maximum efficiency. Obviously in a single circuit the two desired effects tend to cancel each other, and therefore to limit the distance of detection. Similar difficulty characterized the receiver, for a good radiator is a good absorber,

and that very quality disables it to store up and hold the effect of a train of waves, until enough is accumulated to break down the coherer, as detection requires.

Since the difficulty was inherent in a single circuit, whether at one end or the other, Marconi used two in both transmitter and receiver, four in all. In each station he used one circuit to obtain one of the necessary advantages and the other circuit to secure the other advantage. The antenna (or open) circuits he made "good radiators" (or absorbers). The closed circuits he constructed as "good conservers." By coupling the two at each end loosely he secured from their combination the dual advantages he sought. At the transmitter, the closed circuit, by virtue of its capacity for conserving energy, gave persistent oscillation, which passed substantially undiminished through the coupling transformer to the "good radiator" open circuit and from it was discharged with little loss of energy into the ether. Thence it was picked up by the "good absorber" open circuit and passed, without serious loss of energy, through the coupling transformer, into the closed "good conserving" circuit, where it accumulated to break the coherer and give detection.

Moreover, and for present purposes this is the important thing, Marconi brought the closed and open circuits into almost complete harmony by placing variable inductance in each. Through this the periodicity of the open circuit was adjusted automatically to that of the closed one; and, since the circuits of the receiving station were similarly adjustable, the maximum resonance was secured throughout the system. Marconi thus not only solved the dilemma of a single circuit arrangement, he attained the maximum of resonance and selectivity by providing in each circuit independent means of tuning.

In 1911 this solution was held inventive, as against Lodge, Marconi's prior patents, Braun and other references, in *Marconi* v *British Radio Tel. & Tel. Co.*, 27 T. L. R. 274. Mr. Justice Parker carefully reviewed the prior art, stated the problem, Marconi's solution, and in disposing of Braun's specification concluded it "did not contain even the remotest suggestion of the problem . . . , much less any suggestion bearing on its solution. . . ." As to Lodge, Mr. Justice Parker observed, referring first to Marconi:

". . . It is important to notice that *in the receiver* the mere introduction of two circuits instead of one was no novelty. A

figure in Lodge's 1897 patent shows the open circuit of his receiving aerial linked through a transformer with a closed circuit containing the coherer, *his idea being, as he states, 'to leave his receiving aerial to vibrate electrically without disturbance from attached wires.* This secondary circuit, as shown, *is not tuned to, nor can it be tuned to,* the circuit of the aerial. This, in my opinion, is exceedingly strong evidence that Marconi's 1900 invention was not so obvious as to deprive it of subject matter. In the literature quoted there is no trace of the idea underlying Mr. Marconi's invention, nor, so far as I can see, a single suggestion from which a competent engineer could arrive at this idea." (Emphasis added.)

It was therefore clearly Mr. Justice Parker's view, in his closer perspective to the origin of the invention and the references he considered, that in none of them, and particularly not in Lodge or Braun, was there anticipation of Marconi's solution.

He did not mean that the references did not apply "the principle of resonance as between transmitter and receiver" or utilize "the principle of sympathetic resonance for the purpose of detection of ether waves." For he expressly attributed to Lodge, in his 1894 lectures, explanation "with great exactness [of] the various difficulties attending the full utilization" of that principle. And in referring to Marconi's first patent, of 1896, the opinion states that Marconi "*for what it was worth* . . . tuned the two circuits [i. e., the sending and receiving ones] together as Hertz had done." (Emphasis added.)

From these and other statements in the opinion it is obvious that Mr. Justice Parker found Marconi's invention in something more than merely the application of the "principle of resonance," or "sympathetic resonance," or its use to "tune" together the transmitting and receiving circuits. For Marconi in his own prior inventions, Lodge and the other references, in fact all who had constructed any system using Hertzian waves capable of transmitting and detecting sound, necessarily had made use, in some manner and to some extent, of "the principle of resonance" or "sympathetic resonance." That principle is inherent in the idea of wireless communication by Hertzian waves. So that, necessarily, all the prior conceptions included the idea that common periodicity must appear in all of the circuits employed.

Nor did Mr. Justice Parker's opinion find the inventive feature in the use of two circuits instead of one, at any rate in the receiver. For he expressly notes this in Lodge. But he points out that Lodge added the separate circuit "to leave his receiving aerial

free to vibrate electrically without disturbance from attached wires." And he goes on to note that this secondary (or closed) circuit not only was not, but could not be, "tuned" to the aerial circuit. And this he finds "exceedingly strong evidence" that "Marconi's 1900 invention was not so obvious as to deprive it of subject matter." Lodge had "tuned" the antenna circuit, by placing in it a variable inductance. But he did not do this or accomplish the same thing by any other device, such as a condenser, in the closed circuit. And the fact that so eminent a scientist, the one who in fact posed the problem and its difficulties, did not see the need for extending this "independent tuning" (to use Marconi's phrase) to the closed circuit, so as to bring it thus in tune with the open one, was enough to convince Mr Justice Parker, and I think rightly, that what Marconi did over Lodge was not so obvious as to be without substance.

In short, Mr. Justice Parker found the gist of Marconi's invention, not in mere application of the general principle or principles of resonance to a four-circuit system, or in the use of four circuits or the substitution of two for one in each or either station; but, as petitioner now contends, in recognition of the principle that, whether in the transmitter or the receiver, attainment of the maximum resonance required that means for tuning the closed to the open circuit be inserted in both. That recognized, the method of accomplishing the adjustment was obvious, and different methods, as by using variable inductance or a condenser, were available. As petitioner's reply brief states the matter, "The Marconi invention was not the use of a variable inductance, *nor* indeed *any other specific way* of tuning an antenna—before Marconi it was known that electrical circuits could be tuned or not tuned, by inductance coils or condensers. His broad invention was *the combination of a tuned antenna circuit* and *a tuned closed circuit*." (Emphasis added.) And it is only in this view that the action of the Patent Office in finally awarding the patent to Marconi can be explained or sustained, for it allowed claims both limited to and not specifying variable inductance. That feature was essential for both circuits in principle, but not in the particular method by which Marconi accomplished it. And it was recognition of this which eventually induced allowance of the claims, notwithstanding the previous rejections on Lodge, Stone and other references including all in issue here.

In the perspective of this decade, Marconi's advance, in requiring "independent tuning," that is, positive means of tuning

located in both closed and open circuits, seems simple and obvious. It was simple. But, as is often true with great inventions, the simplest and therefore generally the best solution is not obvious at the time, though it becomes so immediately it is seen and stated. Looking back now at Edison's light bulb one might think it absurd that highly useful and beneficial idea had not been worked out long before, by anyone who knew the elementary laws of resistance in the field of electric conduction. But it would be shocking, notwithstanding the presently obvious character of what Edison did, for any court now to rule he made no invention.

The same thing applies to Marconi. Though what he did was simple, it was brilliant, and it brought big results. Admittedly the margin of difference between his conception and those of the references, especially Lodge and Stone, was small. It came down to this, that Lodge saw the need for and used means for performing the function which variable inductance achieves in the antenna or open circuit, Stone did the same thing in the closed circuit, but Marconi first did it in both. Slight as each of these steps may seem now, in departure from the others, it is as true as it was in 1911, when Mr. Justice Parker wrote, that the very fact men of the eminence of Lodge and Stone saw the necessity of taking the step for one circuit but not for the other is strong, if not conclusive, evidence that taking it for both circuits was not obvious. If this was so clearly indicated that anyone skilled in the art should have seen it, the unanswered and I think unanswerable question remains, why did not Lodge and Stone, both assiduously searching for the secret and both preeminent in the field, recognize the fact and make the application? The best evidence of the novelty of Marconi's advance lies not in any judgment, scientific or lay, which could now be formed about it. It is rather in the careful, considered and substantially contemporaneous judgments, formed and rendered by both the patent tribunals and the courts when years had not distorted either the scientific or the legal perspective of the day when the invention was made. All of the references now used to invalidate Marconi were in issue, at one time or another, before these tribunals, though not all of them were presented to each. Their unanimous conclusion, backed by the facts which have been stated, is more persuasive than the most competent contrary opinion formed now about the matter could be.

It remains to give further attention concerning Stone. Admittedly his original application did not require tuning, in Marconi's sense, of the antenna circuit, though it specified this for the closed one. He included variable inductance in the latter, but not in the former. His device therefore was, in this respect, exactly the converse of Lodge. But it is said his omission to specify the function (as distinguished from the apparatus which performed it) for the antenna circuit was not important, because the function was implicit in the specification and therefore supported his later amendment, filed more than a year following Marconi's date, expressly specifying this feature for the open circuit.

Substantially the same answer may be made to this as Mr. Justice Parker made to the claim based on Lodge. Tuning both circuits, that is, including in each independent means for variable adjustment, was the very gist of Marconi's invention. And it was what made possible the highly successful result. It seems strange that one who saw not only the problem, but the complete solution, should specify only half what was necessary to achieve it, neglecting to mention the other and equally important half as well, particularly when, as is claimed, the two were so nearly identical except for location. The very omission of explicit statement of so important and, it is claimed, so obvious a feature is evidence it was neither obvious nor conceived. And the force of the omission is magnified by the fact that its author, when he fully recognized its effect, found it necessary to make amendment to include it, after the feature was expressly and fully disclosed by another. Amendment under such circumstances, particularly with respect to a matter which goes to the root rather than an incident or a detail of the invention, is always to be regarded critically and, when the foundation claimed for it is implicit existence in the original application, as it must be, the clearest and most convincing evidence should be required when the effect is to give priority, by backward relation, over another application intermediately filed.

Apart from the significance of omitting to express a feature so important, I am unable to find convincing evidence the idea was implicit in Stone as he originally filed. His distinction between "natural" and "forced" oscillations seems to me to prove, in the light of his original disclosure, not that "tuning" of the antenna circuit as Marconi required this was implicit, but rather

that it was not present in that application at all. It is true he sought, as Marconi did, to make the antenna circuit at the transmitter the source of waves of but a single periodicity and the same circuit at the receiver an absorber only of the waves so transmitted. But the methods they used were not the same. Stone's method was to provide "what are *substantially forced* vibrations" in the transmitter's antenna circuit and, at the receiver, to impose "between the vertical conductor [the antenna] . . . and the translating devices [in the closed circuit] [other] *resonant circuits attuned* to the particular frequency of the electro-magnetic waves which it is desired to have operate the translating devices." (Emphasis added.) In short he provided for "tuning," as Marconi did, the transmitter's closed circuit, the receiver's closed circuit and the intermediate circuits which he interposed in the receiver between the open or antenna one and the closed one. But nowhere did he provide for or suggest "tuning," as Marconi did and in his meaning, the antenna circuit of the transmitter or the antenna circuit of the receiver. For resonance in the former he depended upon the introduction, from the closed circuit, of "substantially forced electric vibrations" and for selectivity in the latter he used the intermediate tuned circuits. Stone and Marconi used the same means for creating persistent oscillation, namely, the use of the separate closed circuit; and in this both also developed single periodicity to the extent the variable inductance included there and there only could do so. But while both created persistent oscillation in the same way, Marconi went farther than Stone with single periodicity and secured enhancement of this by placing means for tuning in the antenna circuit, which admittedly Stone nowhere expressly required in his original application. And, since this is the gist of the invention in issue and of the difference between the two, it will not do to dismiss this omission merely with the statement that there is nothing to suggest that Stone "did not desire to have those circuits tuned." Nor in my opinion do the passages in the specifications relied upon as "suggesting" the "independent" tuning of the antenna circuits bear out this inference.

When Stone states that "the vertical conductor at the transmitter station is made the source of . . . waves of but a single periodicity," I find nothing to suggest that this is accomplished by specially tuning that circuit, or, in fact, anything more than that this circuit is a good conductor sending out the single period waves

Co., supra. The amendment here should receive the same fate as befell the one there involved.

Stone's letters to Baker, quoted in the Court's opinion, show no more than his original application disclosed. There is no hint or suggestion in them of tuning the antenna circuits "independently" as Marconi did. And the correspondence gives further proof he contemplated introducing the inductance coil (or a device equivalent in function) into the closed circuit, but expressed no idea of doing the same thing in the open one.

In my opinion therefore the judgment should be reversed, in so far as it holds Marconi's broad claims invalid.
